In the elevated districts, natural excavations sometimes of great extent are found; and some naturalists have imagined that one or two mountains presented volcanic appearances. The rivers are numerous, but seldom navigable: the principal are the Enns, the Muhr, the Drave, and the Save. The climate presents great discrepancies, arising from the greater or less elevation of the soil. In Upper Styria the air is elastic, pure, and cold: winter begins in November, and the snow lies on the hills till May. In Lower Styria the climate is more temperate; but, though the air is in general of great purity, endemic fevers prevail, and the constitutional imbecility or idiocy called Cretinism is very common. The quantity of rain is less than might be expected, not exceeding fifteen inches in the year. The soil of Styria is, with the exception of the higher mountains, fertile, and produces wheat, barley, oats, rye, and, in the warmer situations, maize. The potato, though introduced so lately as the middle of the eighteenth century, is now general. Agriculture is extremely backward, though irrigation is practised extensively.

Styria has long been remarkable for the care bestowed on its cattle. They are of middle size, but well shaped, and are driven in summer to the highest parts of the mountains, where, after passing the warm season, they return to the plains. In sheep, at least in the improvement of wool, the Styrians have not yet succeeded, and their horses are chiefly for draught. Poultry is abundant.

Styria produces coal, and several mines of it are wrought; but it is at present not much used in mines and forges. Almost all the metals are found in Styria: gold, silver, and copper, hardly defray the expense of mining; lead is less scarce; but the great produce is iron. The mountain of Erzberg, situated in the north of Styria, was well known to the Romans. Instead of veins and strata, it presents a solid mass of ore, which has been wrought without intermission for eleven centuries; and, although nearly 13,000 tons of pure iron have been obtained annually from it for years, it hardly appears diminished, and the restriction in the quantity made arises chiefly from the limited supply of fuel. At the small town of Turroch is a mine producing the celebrated Prescian steel, used by the Romans for sword blades. The other mines, though less rich, are not inconsiderable; and the total annual produce of iron in Styria is from 16,000 to 20,000 tons. Salt is yet more abundant, particularly at Aussee, from which almost any quantity might be produced, were the demand greater. Cobalt, arsenic, and molybdena, occur in Styria; and zinc, antimony, and bismuth, rarely.

The manufactures of Styria are of course principally derived from the mines. The country contains in all 200 forges, and about thirty manufacturing establishments, in which it is computed that 300,000 sickles, and a still larger quantity of scythes, are made annually. Next

to these in importance are the copper forges, and various preparations of sulphate of iron, alum, saltpetre, earthenware, gunpowder, and sulphur. The flax raised in this country is made into coarse linen, or exported unwrought: the women are much employed in the fields. The exports consist of metals, corn, wine, flax, clover seed, cattle; the imports comprise woollens, linens, silks, tobacco, oil, and groceries.

The Styrians have the hospitality and frankness of an agricultural people, but are as yet very imperfectly educated; the great majority are Roman Catholics; but the Protestants enjoy a full, and the Jews a limited toleration. In regard to government, the Styrians have a parliament under the name of States, composed of four orders, the higher clergy, the nobility, the deputies from the landholders, and the deputies from the towns.

Pliny and Strabo considered the inhabitants as descended from the Boii and Taurisci. They are described as altogether uncivilised, and as harassing the adjoining provinces by their incursions, till the reign of Tiberius (A. D. 8), when Styria was subdued, and included in the province of Noricum. During the period of its remaining in the Roman hands, considerable improvements took place, towns being built at the more important stations, tillage diffused, and in the fourth century Christianity introduced. But Styria was almost as unfortunate in the repeated invasions of the barbarians as the adjoining provinces of Illyria and Pannonia. History records an invasion of southern Germany by the Magyars, the conquerors of Hungary, and their expulsion from the limits of the empire by Otho I. in 933: the reconquered territory was divided into a number of principalities, one of which, called the county of Steyr, rose by gradual and successive augmentations to its present extent. In 1172 it was annexed to Austria, and has since been governed either by the sovereign of that country, or by a member of his family.

STY'THY, *v. a.* See STITHY. To forge on an anvil.

By the forge that *stythied* Mars his helm,
I'll kill thee every where, yea, o'er and o'er.

Shakespeare.

STYX, in mythology, a celebrated river of hell, round which it flows nine times. The gods held the waters of the Styx in such veneration that to swear by them was reckoned an oath altogether inviolable. If any of the gods had perjured themselves, Jupiter obliged them to drink the waters of the Styx, which lulled them for one whole year into a senseless stupidity, for the nine following years they were deprived of the ambrosia and the nectar of the gods, and, after the expiration of the years of their punishment, they were restored to the assembly of the deities, and to all their original privileges. It is said that this veneration was shown to the Styx because it received its name from the nymph Styx, who with her three daughters assisted Jupiter in his war against the Titans. Styx was a river which it was necessary for departed shades to pass before they could enter the infernal regions; and it was the office of Charon to ferry them

over in a boat which was kept for that purpose. The ghosts of those who had not been honored with the rites of sepulture were obliged to wander 100 years before Charon could admit them into his boat to convey them before the judges of Hades. Mythological writers have said that the Greeks learned it from the Egyptians, which is indeed probable enough; that the Egyptians framed both this and some other fables relating to the dead, from certain customs peculiar to their country; that in particular there was, not far from Memphis, a famous burying-place, to which the dead bodies were conveyed in a boat across the lake Acherusia; and that Charon was a boatman who had long officiated in that service. The learned Dr. Blackwell says, in his *Life of Homer*, that, in the old Egyptian language, Charon signified ferryman.

STYX, a sea nymph, daughter of Oceanus and Tellus. She married the giant Pallas, son of Crius and Eurybia, by whom she had three daughters, all goddesses, Victory, Strength, and Valor. She and her daughters assisted Jupiter against the giants; and she gave name to the infernal river by which the gods swore.

SUANES, **SUANETI**, **SUANI**, or **SOANES**, a people of Asia, who inhabit one of the four divisions of Imeritia. They are chiefly employed in agriculture and rearing cattle. Major Rennell supposes them to be the descendants of a people of the same name and country, mentioned by Strabo. They were then a numerous and powerful nation, governed by a king and national council of 300. They collected gold in their rivers, washed down from the mountains, by sinking sheep-skins in them, with the wool uppermost; whence Strabo derives the origin of the fable of the Golden Fleece. See **ARGO**, **ARGONAUTS**, **COLCHIS**, and **MINGRELIA**.

SUARDONES, an ancient nation of Germany. Tacitus de Germ. 40.

SUARES, or **SUAREZ** (Francis), a Spanish Jesuit, born in Grenada, 5th of January, 1548. He was professor of theology at Alcalá, Salamanca, Rome, and Coimbra in Portugal. He died at Lisbon in 1617, with great ease and resignation. His memory was astonishing: he could repeat the whole of his voluminous works by heart. His writings fill twenty-three folio volumes, mostly on theological and moral subjects. His *Treatise of Laws* has been reprinted in this country. His defence of the Catholic Faith against the errors of England was written at the request of pope Paul V. This book was publicly burnt at London by order of James I.

SUA'SIVE, *adj.* Lat. *suadeo*. Having power to persuade.

It had the passions in perfect subjection; and though its command over them was but *suasive* and political, yet it had the force of coercion, and despotical. *South.*

SUA'VITY, *n. s.* Fr. *suavité*; Lat. *suavitas*. Sweetness to the senses.

She desired them for rarity, pulchritude, and *suavity*. *Browne.*

SUBACID, *adj.* Lat. *sub* and *acidus*. Sour in a small degree.

The juice of the stem is like the chyle in the ani-

mal body, not sufficiently concocted by circulation and is commonly *subacid* in all plants.

Arbuthnot on Aliments.

SUBACRID, *adj.* Sub and acrid. Sharp and pungent in a small degree.

The green cholera of a cow tasted sweet, bitter, *subacrid*, or a little pungent, and turned syrup of violets green. *Floyer.*

SUBACT, *v. a.* Lat. *subactus*. To reduce; to subdue.

Tangible bodies have no pleasure in the consort of air, but endeavour to *subact* it into a more dense body. *Bacon.*

There are of concoction two periods: the one assimilation, or absolute conversion and *subaction*; the other maturation: whereof the former is most conspicuous in living creatures, in which there is an absolute conversion and assimilation of the nourishment into the body. *Id. Natural History.*

SUBAH, the general name of the viceroyships, or greater governments, into which the Mogul empire was divided, consisting of several provinces.

SUBAHDAR, the viceroy, lord-lieutenant, or governor, holding a subah; the same as nabob or nazim. Also the black commander of a company of seapoys.

SUBAHDAREE, or **SUBAHSHIP**, the jurisdiction of subahdar; the same with nizamut.

SUBALTERN, *adj.* Fr. *subalterne*. Inferior; subordinate; that which in different respects is both superior and inferior.

Love's *subalterns*, a duteous band,
Like watchmen round their chief appear;

Each had his lantern in his hand,
And Venus, masked, brought up the rear. *Prior.*

One, while a *subaltern* officer, was every day complaining against the pride of colonels towards their officers, yet, after he received his commission for a regiment, he confessed the spirit of colonelship was coming fast upon him, and it daily increased to his death. *Swift.*

This sort of universal ideas, which may either be considered as a genus or species, is called *subaltern*. *Watts.*

SUBALTERN (Fr. *officiers subalternes*), *subaltern* officers. This word is used among the French, as with us, to signify all officers of a certain inferior degree, viz. les *subalternes*, the *subalterns*. All officers under the rank of major, technically considered, are *subalterns*; captains of troops and companies, in an effective battalion, under arms, are in a *subaltern* station, and subject to the word of command given by one person; hence *subaltern*,—from the Latin *sub* and *alter*—in the same manner that lieutenants, cornets, and ensigns, are under the control of captains of troops or companies.

SUBBEADLE, *n. s.* Sub and beadle. An under beadle.

They ought not to execute those precepts by simple messengers, or *subbeadles*, but in their own persons. *Ayliffe.*

SUBBULGUR, a town in the Mahratta territories, in the province of Agra, situated sixty-five miles south-west from the city of Agra, is surrounded by a high stone wall, in good repair, with a number of bastions; but the artillery is very insufficient. One side of the fort stands on the edge of a deep precipice. Between Sub-

bulghur and Bejghur, to the south, the country is tolerably well cultivated.

Also a town in the province of Delhi, on the east side of the Ganges, twelve miles south from Hurdwar. There is here an extensive line of fortification enclosing the town, but which exhibits little more than naked walls falling to decay. Much of the ground within the fort is under cultivation.

SUBCELESTIAL, *adj.* Sub and celestial. Placed beneath the heavens.

The most refined glories of *subcelestial* excellencies are but more faint resemblances of these.

Glanville.

SUBCLAVIAN, *adj.* Lat. *sub* and *clavus*.

Subclavian is applied to any thing under the armpit or shoulder, whether artery, nerve, vein, or muscle.

Quincy.

The chyle first mixeth with the blood in the *subclavian* vein, and enters with it into the heart, where it is very imperfectly mixed, there being no mechanism nor fermentation to convert it into blood, which is effected by the lungs.

Arbuthnot.

SUBCLAVIAN ARTERIES. See ANATOMY.

SUBCLAVIUS. See ANATOMY.

SUBCONSTELLATION, *n. s.* Sub and constellation. A subordinate or secondary constellation.

As to the picture of the seven stars, if thereby he meant the Pleiades, or *subconstellation* upon the back of Taurus, with what congruity they are described, in a clear night an ordinary eye may discover.

Broune's Vulgar Errors.

SUBCONTRACTED, *part. adj.* Sub and contracted. Contracted after a former contract.

Your claim,

I bar it in the interest of my wife,

'Tis she is *subcontracted* to this lord,

And I her husband contradict your banes.

Shakspeare. King Lear.

SUBCONTRARY, *adj.* Sub and contrary. Contrary in an inferior degree.

If two particular propositions differ in quality, they are contraries: as, some vine is a tree; some vine is not a tree. These may be both true together, but they can never be both false.

Watts.

SUBCONTRARY POSITION, in geometry, is when two equiangular triangles are so placed as to have one common angle at the vertex, and yet their bases not parallel; consequently the angles at the bases are equal, but on the contrary sides.

SUBDEACON, *n. s.* Lat. *subdiaconus*.

In the Romish church they have a *subdeacon*, who is the deacon's servant.

Ayliffe's Parergon.

SUBDEACON, an inferior minister, who anciently attended the altar, prepared the sacred vessels, delivered them to the deacons in time of divine service, attended the doors of the church during communion service, went on the bishop's embassies with his letters or messages to foreign churches, and was invested with the first of the holy orders. They were so subordinate to the superior rulers of the church that, by a canon of the council of Laodicea, they were forbidden to sit in the presence of a deacon without his leave. According to the canons, a person must be twenty-two years of age to be promoted to the order of *subdeacon*. See DEACON.

SUBDEAN, *n. s.* Lat. *subdecanus*. The vicegerent of a dean.

Whenever the dean and chapter confirm any act, that such confirmation may be valid, the dean must join in person, and not in the person of a deputy or *subdean* only.

Ayliffe.

SUBDELEGATE; appointed to act under another, or one who is so.

SUBDERISORIOUS, *adj.* Lat. *sub* and *derisor*. Scoffing or ridiculing with tenderness and delicacy. Not used.

The *subderisorius* mirth is far from giving any offence to us: it is rather a pleasant *condiment* of our conversation.

More.

SUBDIVERSIFY, *v. a.* Sub and diversify. To diversify again what is already diversified.

The same wool one man felts into a hat, another weaves it into cloth, another into arras; and these variously *subdiversified* according to the fancy of the artificer:

Hale.

SUBDIVIDE, *v. a.* } Fr. *subdiviser*. Sub
SUBDIVISION, *n. s.* } and divide. To divide a part into yet more parts: the noun substantive corresponding.

When Brutus and Cassius were overthrown, soon after Antonius and Octavianus brake and *subdivided*.

Browne.

The glad father glories in his child,

When he can *subdivide* a fraction.

Roscommon.

When the progenies of Cham and Japhet swarmed into colonies, and those colonies were *subdivided* in many others, in time their descendants lost the primitive rights of divine worship, retaining only the notion of one deity.

Dryden.

In the decimal table the *subdivisions* of the cubit, as span, palm, and digit, are deduced from the shorter cubit.

Arbuthnot.

When any of the parts of any idea are farther divided, in order to a clear explication of the whole, this is called a *subdivision*; as when a year is divided into months, each month into days, and each day into hours, which may be farther *subdivided* into minutes and seconds.

Watts's Logick.

SUB'DOLOUS, *adj.* Lat. *subdolos*. Cunning; subtle; sly.

In his own case he might have thought it a *subdulous* evasion; a forced succession wholly nugatory on the footing of worldly success.

Whyte's Poems, Notes.

SUBDOMINANT, in music, a name given by M. Rameau to the fourth note of the tone, which of consequence is the same interval from the tonic when descending as the dominant in rising. This denomination arises from the affinity which this author finds by inversion between the minor mode of the subdominant and the major mode of the tonic. See DOMINANT and MUSIC.

SUBDUCE, *v. a.* } Lat. *subduco, subductus*.

SUBDUCT, } To withdraw; take away;

SUBDUCTION, *n. s.* } subtract: the noun substantive corresponding.

Or nature failed in me, and left some part

Not proof enough such object to sustain;

Or, from my side *subducting*, took perhaps

More than enough. *Milton's Paradise Lost.*

Take the other operation of arithmetick, *subduction*: if out of that supposed infinite multitude of antecedent generations we should *subduce* ten, the residue must be less by ten than it was before, and yet still the quotient must be infinite.

Hale.

Possibly the Divine beneficence *subducting* that influence which it communicated from the time of their

first creation, they were kept in a state of immortality till that moment of the *subduction*.

Id. Origin of Mankind.

SUBDUE', *v. a.* } *Lat. subdo, or subjugo.*
 SUBDUÉMENT, *n. s.* } To crush; oppress; over-
 SUBDUER. } power; sink; conquer;

tame: the noun substantives corresponding.
 Be fruitful and replenish the earth, and *subdue* it.
Gen. i. 28.

Them that rose up against me hast thou *subdued*
 under me. *2 Sam. xxii. 40.*

Great god of might, that reigneth in the mind,
 And all the body to thy hest dost frame:
 Victor of gods, *subduer* of mankind,
 That dost the lions and fell tygers tame,
 Who can express the glory of thy might? *Spenser.*

Nothing could have *subdued* nature
 To such a lowness, but his unkind daughters.

Shakspeare.

As hot as Perseus, spur thy Phrygian steed,
 Bravely despising forfeits and *subduements.* *Id.*
 Augustus Cæsar *subdued* Egypt to the Roman em-
 pire. *Peacham.*

Nor 'st unwholesome to *subdue* the land
 By often exercise; and, where before
 You broke the earth, again to plow. *May's Virgil.*

If aught were worthy to *subdue*

The soul of man. *Milton.*

Their curious eye

Discerns their great *subduer's* awful men
 And corresponding features fair. *Phillips.*

The Romans made those times the standard of
 their wit, when they *subdued* the world. *Sprat.*

Figs are great *subduers* of acrimony, useful in
 hoarseness and coughs, and extremely emollient.

Arbuthnot.

SUB'DUPLE, *adj.* } Fr. *subduple*; Lat. *sub*
 SUBDUPLICATÉ, *n. s.* } and *duplus*. Containing
 one part of two.

As one of these under pulleys doth abate half of
 that heaviness which the weight hath in itself, and
 cause the power to be in a *subduple* proportion unto
 it, so two of them do abate half of that which re-
 mains, and cause a subquadruple proportion, and
 three a subseptuple. *Wilkins's Mathematical Magick.*

The motion generated by the forces, in the whole
 passage of the body or thing through that space, shall
 be in a *subduplicate* proportion of the forces.

Newton's Opticks.

SUBDUPLICATE RATIO is, when any number or
 quantity is contained in another twice. Thus
 three is said to be *subduple* of six, as six is *duple*
 of three. See RATIO.

SUBDUPLICATE RATIO of any two quantities
 is the ratio of their square roots.

SUBER, the cork-tree. See QUERCUS.

SUBERAS, or SUBERAT, from *suber*, the
 cork-tree. A salt formed by the combination of
 the suberic acid, or acid of cork, with different
 bases. 'These salts,' says Dr. Thomson in his
 System of Chemistry, vol. iii. p. 434, 'have been
 described with a good deal of detail, by Bouil-
 lon la Grange. They have in general a bitter
 taste, and are decomposed by heat.' The doctor
 describes seven species, viz., 1. 'S. of alumina.
 This salt does not crystallise. When its solution
 is evaporated by a moderate heat, in a wide ves-
 sel, the salt obtained is of a yellow color, trans-
 parent, having a styptic taste, and leaving an im-
 pression of bitterness on the tongue. When too
 much heat is employed it melts and blackens. It
 reddens the tincture of turnsole, and attracts

moisture from the air. Before the blow-pipe it
 swells up, the acid is volatilised and decomposed,
 and nothing remains but the alumina.

2. 'S. of ammonia crystallises in parallelepipedic.
 Its taste is saltish and leaves an impression of
 bitterness. It reddens vegetable blues. It is
 very soluble in water. It attracts moisture from
 the air. When placed upon burning coals it
 loses its water of crystallisation, and swells up;
 and before the blow-pipe it evaporates entirely.
 It is decomposed by the aluminous and magne-
 sian salts.

3. 'S. of barytes does not crystallise. Heat
 makes it swell up and melts it. It is scarcely
 soluble in water except there be an excess of
 acid. It is decomposed by most of the salts, ex-
 cept the barytic salts and the fluat of lime.

4. 'S. of lime does not crystallise. It is per-
 fectly white; it has a saltish taste; it does not
 redden the tincture of turnsole. It is very spar-
 ingly soluble in water, except when hot; and, as
 the solution cools, most of the salt precipitates
 again. When placed upon burning coals it swells
 up, the acid is decomposed, and there remains
 only the lime in the state of powder. It is decom-
 posed by 1. Muriate of alumina: 2. Carbonates
 of potash and soda: 3. Fluat of magnesia: 4.
 Phosphates of alumina and soda: 5. Borate of
 potash: 6. All the metallic solutions.

5. 'S. of magnesia is in the form of a powder;
 it reddens the tincture of turnsole. It has a bit-
 ter taste; it is soluble in water, and attracts some
 moisture when exposed to the air. When heated
 it swells up and melts: before the blow-pipe the
 acid is decomposed, and the magnesia remains
 in a state of purity. It is decomposed by 1.
 Muriate and phosphate of alumina: 2. Nitrates
 of lime and alumina: 3. Borate of potash: 4.
 Fluat of soda.

6. 'S. of potash ought to be formed by means
 of crystallised carbonat of potash. It crystallises
 in prisms having four unequal sides. It has a
 bitter saltish taste, and it reddens vegetable blues.
 It is very soluble in water. Caloric melts it, and
 at last volatilises the acid. It is decomposed by
 most of the metallic salts, and by sulphate of alu-
 mina, muriate of alumina and of lime; nitrate of
 alumina and of lime; and phosphate of alumina.

7. 'S. of soda does not crystallise. It reddens
 the tincture of turnsole. Its taste is slightly bit-
 ter. It is very soluble in water and in alcohol.
 It attracts moisture from the air. Caloric pro-
 duces the same effect on it that it does on sube-
 rat of potash, No. 6. It is decomposed by the
 calcareous, aluminous, and magnesian salts.

SUBERIC, from Lat. *suber*, the cork-tree.
 Of or belonging to cork, or the cork-tree; con-
 sisting of the essence of cork.

SUBERIC ACID, or the acid of cork, one of the
 many new acids recently discovered by the inge-
 nuity of modern chemists. 'Cork,' says Dr.
 Thomson, in his System of Chemistry, ii. 140,
 'a substance too well known to require any de-
 scription, is the bark of a tree which bears the
 same name. By means of nitric acid Brug-
 natelli converted it into an acid, which has
 been called the suberic acid, from *suber*.'
 'Several chemists affirmed that this acid was the
 oxalic, because it possesses several properties in

common with it. These assertions induced Bouillon La Grange to undertake a set of experiments on suberic acid. These experiments, which have been published in the twenty-third volume of the *Annales de Chimie*, completely establish the peculiar nature of suberic acid, by showing that it possesses properties different from those of any other acid. Suberic acid may be formed by pouring six parts of nitric acid of the specific gravity 1.261 on one part of cork grated down, or simply broken down into small pieces, and distilling the mixture with a gentle heat as long as red vapors continue to escape. As the distillation advances, a yellow matter like wax appears on the surface of the liquid. While the matter contained in the retort is hot, it is to be poured into a glass vessel, placed upon a sand-bath over a gentle fire, and constantly stirred with a glass rod. By these means it becomes gradually thick. As soon as white vapors, exciting a tickling in the throat, begin to disengage themselves, the vessel is removed from the bath, and the mass continually stirred till it is almost cold. By these means an orange-colored mass is obtained of the consistence of honey, of a strong and sharp odor while hot, but having a peculiar aromatic smell when cold. On this mass twice its weight of boiling-water is to be poured, and heat applied till it becomes liquid; and then that part of it which is insoluble in water is to be separated by filtration. The filtered liquor becomes muddy; on cooling it deposits a powdery sediment, and a thin pellicle forms on its surface. The sediment is to be separated by filtration, and the liquor reduced to a dry mass by evaporating in a gentle heat. This mass is suberic acid. It is still a little colored, owing to some accidental mixture; from which it may be purified, either by saturating it with potass, and precipitating it by an acid, or by boiling it with charcoal powder. Suberic acid thus obtained is not crystallisable, but, when precipitated from potass by an acid, it assumes the form of a powder; when obtained by evaporation, it forms thin irregular pellicles. Its taste is acid and slightly bitter; and, when dissolved in a small quantity of boiling water, it acts upon the throat, and excites coughing. It reddens vegetable blues; and, when dropped into a solution of indigo in sulphuric acid (the liquid blue of this country), it changes the color of the solution and renders it green. Water at 60° or even 70° dissolves only one 57-6th part of its weight of suberic acid; and if the acid be very pure only one 144th part: boiling water on the contrary dissolves half its weight of it. When exposed to the air it attracts moisture, especially if it be impure. When exposed to the light of day, it becomes at last brown; and this effect is produced much sooner by the direct rays of the sun. When heated in a matrass the acid sublimes, and the inside of the glass is surrounded with zones of different colors. If the sublimation be stopped at the proper time, the acid is obtained on the sides of the vessel in small points formed of concentric circles. When exposed to the heat of the blow-pipe, on a spoon of platinum, it first melts, then becomes pulverulent, and at last sublimes entirely, with a smell resembling that of cebacic acid. It is not altered

by oxygen gas: the other acids do not dissolve it completely. Alcohol devolves an aromatic odor, and an ether may be obtained by means of this acid. It converts the blue color of nitrate of copper into a green; the sulphate of copper into a green; green sulphate of iron to a deep yellow; and sulphate of zinc to a golden yellow. It has no action either on platinum, gold, or nickel; but it oxidates silver, mercury, lead, tin, iron, bismuth, arsenic, cobalt, zinc, antimony, manganese, and molybdenum. With alkalis, earths, and metallic oxides, it forms compounds named *suberats*. See *SUBERAT*. Its affinities are as follows:—barytes, potass, soda, lime, ammonia, magnesia, alumina.

M. Chevreuil obtained the suberic acid by mere digestion of the nitric acid on grated cork, without distillation, and purified it by washing with cold water. Twelve parts of cork may be made to yield one of acid. When pure, it is white and pulverulent, having a feeble taste, and little action on litmus. It is soluble in eighty parts of water at 55° 30' Fahrenheit, and in thirty-eight parts at 140°. It is much more soluble in alcohol, from which water throws down a portion of the suberic acid. It occasions a white precipitate when poured into acetate of lead, nitrates of lead, mercury, and silver, muriate of tin, and protosulphate of iron. It affords no precipitate with solutions of copper or zinc. The suberates of potassa, soda, and ammonia, are very soluble. The two latter may be readily crystallised. Those of barytes, lime, magnesia, and alumina, are of sparing solubility.

SUBJA'CENT, *adj.* Lat. *subjacens*,
SUBJECT, *v. a., adj., & n. s.* } *subjectus*. Lying
SUBJECTION, *n. s.* } under: to put un-
SUBJECTIVE, *adj.* } der; to reduce to submission; enslave; expose; make liable, subservient, or accountable: as an adjective, placed under; liable; obnoxious; being that on which an action operates: the noun substantives correspond: subjective, relating to the subject.

How hard it is now for him to frame himself to *subjection*, that, having once set before his eyes the hope of a kingdom, hath found encouragement.

Spenser.

Because the *subjection* of the body to the will is by natural necessity, the *subjection* of the will unto God voluntary, we therefore stand in need of direction after what sort our wills and desires may be rightly conformed to his.

Hooker.

I live on bread like you, feel want like you,
 Taste grief, need friends, like you: *subjected* thus,
 How can you say to me I am a king?

Shakspeare. Richard II.

Now spurs the lated traveller apace
 To gain the timely inn, and near approaches
 The *subject* of our watch. *Id. Macbeth.*

Every *subject's* duty is the king's,
 But every *subject's* soul is his own. *Id. Henry V.*

The' eastern tower,
 Whose height commands, as *subject*, all the vale
 To see the fight. *Id. Troilus and Cressida.*

Most *subject* is the fattest soil to weeds;
 And he, the noble image of my youth,
 Is overspread with them. *Shakspeare.*

Anger is certainly a kind of baseness, as it appears well in the weakness of those *subjects* in whom it reigns, children, women, old folks, sick folks.

Bacon

Those I call *subjects* which are governed by the ordinary laws and magistrates of the sovereign.

Davies.

Here he would have us fix our thoughts; nor are they too dry a *subject* for our contemplation.

Decay of Piety.

We must understand and confess a king to be a father, a *subject* to be a son; and therefore honour to be by nature most due from the natural *subject* to the natural king.

Holyday.

The angel

Led them direct, and down the cliff as fast

To the *subjected* plain. *Milton.*

He *subjected* to man's service angel wings. *Id.*

Both in *subjection* now to sensual appetite. *Id.*

After the conquest of the kingdom, and *subjection* of the rebels, enquiry was made who there were hat, fighting against the king, had saved themselves by flight. *Hale.*

Hale.

I will not venture on so nice a *subject* with my severe style. *More.*

More.

Christ, since his incarnation, has been *subject* to the Father; and will be so also, in his human capacity, after he has delivered up his mediatorial kingdom. *Waterland.*

Waterland.

Think not, young warriors, your diminished name Shall lose of lustre, by *subjecting* rage

To cool the dictates of experienced age. *Dryden.*

Dryden.

I see thee, in that fatal hour,

Subjected to the victor's cruel power,

Led hence a slave. *Id.*

Id.

All human things are *subject* to decay,

And, when fate summons, monarchs must obey. *Id.*

Id.

Were *subjects* so but only by their choice,

And not from birth did forced dominion take,

Our prince alone would have the public voice. *Id.*

Id.

I enter into the *subject* matter of my discourse. *Id.*

Id.

The blind will always be led by those that see, or fall into the ditch: and he is the most *subjected*, the most enslaved, who is so in his understanding. *Locke.*

Locke.

God is not bound to *subject* his ways of operation to the scrutiny of our thoughts, and confine himself to do nothing but what we must comprehend. *Id.*

Id.

Esau was never *subject* to Jacob, but founded a distinct people and government, and was himself prince over them. *Id.*

Id.

Heroick kings whose high perfections have made them awful to their *subjects*, can struggle with and subdue the corruption of the times. *Davenant.*

Davenant.

If the vessels yield, it *subjects* the person to all the inconveniencies of an erroneous circulation. *Arbutnot.*

Arbutnot.

The superficial parts of mountains are washed away by rains and borne down upon the *subjacent* plains. *Woodward.*

Woodward.

The medal bears each form and name, In one short view, *subjected* to our eye, Gods, emperors, heroes, sages, beauties lie. *Pope.*

My real design is that of publishing your praises to the world; not upon the *subject* of your noble birth. *Swift.*

Swift.

The *subject* must obey his prince, because God commands it, human laws require it. *Id.*

Id.

The *subject* of a proposition is that concerning which any thing is affirmed or denied. *Watts's Logic.*

Watts's Logic.

Certainty, according to the schools, is distinguished into objective and *subjective*; objective is when the proposition is certainly true in itself, and *subjective*, when we are certain of the truth of it. *Watts.*

Watts.

SUBINFEUDATION, in English law, was where the inferior lords, in imitation of their superiors, began to carve out and grant to others minuter estates than their own, to be held of themselves; and were so proceeding downwards in infinitum, till the superior lords observed that by this method of subinfeudation they lost all their feudal profits, of wardships, marriages, and escheats, which fell into the hands of these mesne or middle lords, who were the immediate superiors of the terre-tenant, or him who occupied the land. This occasioned the statute of Westm. 3, or quia emptores, 18 Edw. 1., to be made; which directs that, upon all sales or feoffments of lauds, the feoffee shall hold the same, not of his immediate feoffer, but of the chief lord of the fee of whom such feoffer himself held it. And hence it is held that all manors existing at this day must have existed by immemorial prescription; or at least ever since the 18 Edw. 1. when the statute of quia emptores was made.

SUBINGRESS'ION, *n. s.* Lat. *sub* and *ingressus*. Secret entrance.

The pressure of the ambient air is strengthened upon the accession of the air sucked out; which forceth the neighbouring air to a violent *subingression* of its parts. *Boyle.*

Boyle.

SUBJOIN', *v. a.* Fr. *sub* and *joindre*; Lat. *subjungo*. To add at the end; to add afterwards.

He makes an excuse from ignorance, the only thing that could take away the fault; namely, that he knew not that he was the high-priest, and *subjoins* a reason. *South.*

South.

SUBITO, in the Italian music, is used to signify that a thing is to be performed quickly and hastily: thus we meet with *volti subito*, turn over the leaf quickly.

SUBJUGATE, *v. a.* Fr. *subjuguier*; Lat. *subjugo*. To conquer; subdue; bring under dominion by force.

This was the condition of the learned part of the world, after their *subjugation* by the Turks. *Hale.*

Hale.

O favorite virgin, that hast warned the beast, Whose sovereign dictates *subjugate* the cast! *Prior.* He *subjugated* a king, and called him his vassal. *Baker.*

Baker.

SUBJUNCTION, *n. s.* } Lat. *subjungo*. The SUBJUNCTIVE, *adj.* } state of being subjoined; the act of subjoining: subjoined to something else.

The verb undergoes in Greek a different formation; and in dependence upon, or *subjunction* to, some other verb. *Clarke.*

Clarke.

The verb undergoes a different formation, to signify the same intention as the indicative, yet not absolutely, but relatively to some other verb, which is called the *subjunctive mood*. *Id.*

Id.

SUBJUNCTIVE, or **SUBJUNCTIVE MOOD**, in grammar. See **GRAMMAR**.

SUBLAPSA'RIAN, *adj.* } Lat. *sub* and **SUBLAP'SARY**. } *lapsus*. Done after the fall of man.

The degree of reprobation, according to the *sublapsarian* doctrine, being nothing else but a mere preterition or non-election of some persons whom God left as he touna involved in the guilt of the first Adam's transgression, without any actual per-

sonal sin of their own, when he withdrew some others as guilty as they. *Hammond.*

SUBLAPSARIANS, or INFRALAPSARIANS. See SUPRALAPSARIANS.

SUBLEYRAS (Peter), an eminent French painter born in Languedoc, in 1699. He excelled in history and portraits: and was much patronised by the king and nobility, as well as by foreigners. He painted a grand piece for St. Peter's church at Rome; and died in 1749, aged fifty.

SUBLIMABLENESS, *n. s.* } *Lat. sublimis.*
 SUBLIMATE, *v. a., n. s., & adj.* } Quality of
 SUBLIMATION, *n. s.* } admitting to
 SUBLIME', *adj., n. s., v. a., &* } be sublimat-
 SUBLIMELY, *adv.* [*v. n.*] } ed, or raised
 SUBLIMITY, *n. s.* } by the force
 of fire: sublimate is also used for to raise; exalt; generally: but the noun substantive and adjective are only used chemically: sublimation is defined below: sublime is, high in place; excellent style or sentiment; mien or manner: as a noun substantive, a grand or lofty style: to sublime, synonymous with to sublimate: sublimely is, loftily; grandly: the noun substantive that follows corresponding.

As religion looketh upon him who in majesty and power is infinite, as we ought we account not of it, unless we esteem it even according to that very height of excellency which our hearts conceive, when divine *sublimity* itself is rightly considered. *Hooker.*

In respect of God's incomprehensible *sublimity* and purity, this is also true, that God is neither a mind nor a spirit like other spirits, nor a light such as can be discerned. *Raleigh.*

Enquire the manner of *subliming*, and what metals endure *subliming*, and what body the *sublimate* makes. *Bacon.*

Separation is wrought by weight, in the settlement of liquors, by heat, by precipitation, or *sublimation*; that is, a calling of the several parts up or down, which is a kind of attraction. *Id. Natural History.*

She turns

Bodies to spirits, by *sublimation* strange. *Davies.*
 And as his actions rose, so raise they still their vein

In words, whose weight best suits a *sublimated* strain. *Drayton.*

Study our manuscripts, those myriads
 Of letters, which have passed 'twixt thee and me:
 Thence write our annals, and in them lessons be
 To all, whom love's *subliming* fire invades. *Donne.*

He was *sublime*, and almost tumorous, in his looks and gestures. *Wotton.*

Not only the gross and illiterate souls, but the most ærial and *sublimated*, are rather the more proper fuel for an immaterial fire. *Decay of Piety.*

The precepts of Christianity are so excellent and refined, and so apt to cleanse and *sublimate* the more gross and corrupt, as shews flesh and blood never revealed it. *Id.*

Although thy trunk be neither large nor strong,
 Nor can thy head, not helped itself *sublime*,
 Yet, like a serpent, a tall tree can climb. *Denham.*

They sum'd their pens, and soaring the' air *sublime*

With clang despised the ground. *Milton.*
 My earthly strained to the height

In that celestial colloquy *sublime*. *Id.*

Their hearts were jocund and *sublime*,
 Drunk with idolatry, drunk with wine. *Id.*

His fair large front and eye *sublime* declared
 Absolute rule. *Id.*

Flowers, and then fruit,
 Man's nourishment, by gradual scale *sublimed*,
 To vital spirits aspire. *Id.*

The fancies of most are moved by the inward springs of the corporeal machine, which, even in the most *sublimed* intellectuals, is dangerously influential. *Glanville.*

He obtained another concrete as to taste and smell, and easy *sublimableness*, as common sal ammoniack. *Boyle.*

Sublime on these a tower of steel is reared,
 And dire Tisiphone there keeps the ward. *Dryden.*

Can it be, that souls *sublime*
 Return to visit our terrestrial clime?
 And that the generous mind, released by death,
 Can covet lazy limbs? *Id.*

Art, being strengthened by the knowledge of things, may pass into nature by slow degrees, and so be *sublimed* into a pure genius, which is capable of distinguishing betwixt the beauties of nature and that which is low in her. *Id. Dufresnoy.*

Shall he pretend to religious attainments who is defective and short in moral, which are but the rudiments and first draught of religion, as religion is the perfection, refinement, and *sublimation* of morality? *South.*

In English lays, and all *sublimely* great,
 Thy Homer charms with all his ancient heat. *Parnell.*

The *sublime* rises from the nobleness of thoughts, the magnificence of the words, or the harmonious and lively turn of the phrase; the perfect *sublime* arises from all three together. *Addison.*

Milton's distinguishing excellence lies in the *sublimity* of his thoughts, in the greatness of which he triumphs over all the poets, modern and ancient, Homer only excepted. *Id.*

Easy in stile thy work, in sense *sublime*. *Prior.*

Sublimation differs very little from distillation, excepting that in distillation only the fluid parts of bodies are raised, but in this the solid and dry; and that the matter to be distilled may be either solid or fluid, but *sublimation* is only concerned about solid substances. There is also another difference, namely, that rarefaction, which is of very great use in distillation, has hardly any room in *sublimation*; for the substances which are to be *sublimed*, being solid, are incapable of rarefaction; and so it is only impulse that can raise them. *Quincy.*

The particles of mercury, uniting with the acid particles of spirit of salt, compose mercury *sublimate* and, with the particles of sulphur, cinnabar. *Newton's Opticks.*

Since oil of sulphur per campanam is of the same nature with oil of vitriol, may it not be inferred that sulphur is a mixture of volatile and fixed parts, so strongly cohering by attraction as to ascend together by *sublimation*? *Id.*

The particles of sal ammoniack in *sublimation* carry up the particles of antimony, which will not *sublime* alone. *Id.*

This salt is fixed in a gentle fire, and *sublimes* in a great one. *Arbutnot on Aliments.*

Longinus strengthens all his laws,
 And is himself the great *sublime* he draws. *Pope.*

Meanly they seek the blessing to confine,
 And force that sun but on a part to shine;
 Which not alone the southern wit *sublimes*,
 But ripens spirits in cold northern climes.

Fustian's so *sublimely* bad,
 It is not poetry, but prose run mad.

SUBLIMATE, a chemical preparation, consisting

of quicksilver united with the muriatic acid. See CHEMISTRY and PHARMACY.

SUBLIMATE, CORROSIVE. Bichloride of mercury.

SUBLIMATION is a process by which volatile substances are raised by heat, and again condensed in the solid form. This operation is founded on the same principles as distillation, and its rules are the same, as it is nothing but a dry distillation. Therefore all that has been said on the article **DISTILLATION** is applicable here, especially in those cases where sublimation is employed to separate volatile substances from others which are fixed or less volatile.

Sublimation is also used in other cases; for instance, to combine volatile matters together, as in the operation of the sublimate of mercury; or to collect some volatile substances, as sulphur, the acid of borax, and all the preparations called flowers. The apparatus for sublimation is simple. A matrass or small alembic is generally sufficient for the sublimation of small quantities of matter. But the vessels, and the method of managing the fire, vary according to the nature of the matters which are to be sublimed, and according to the form which is to be given to the sublimate.

The beauty of some sublimate consists in their being composed of very fine, light parts, such as almost all those called flowers; as flowers of sulphur, of benzoin, and others of this kind. When the matters to be sublimed are at the same time volatile, a high cucurbit, to which is adapted a capital, and even several capitals placed one upon another, are employed. The sublimation is performed in a sand-bath, with only the precise degree of heat requisite to raise the substance which is to be sublimed, and the capitals are to be guarded as much as possible from heat. The height of the cucurbit and of the capital seems well contrived to accomplish this intention.

When, along with the dry matter which is to be collected in these sublimate, a certain quantity of some liquor is raised, as happens in the sublimation of acid of borax, and in the rectification of volatile concrete alkali, which is a kind of sublimation, a passage and a receiver for these liquors must be provided. This is conveniently done by using the ordinary capital of the alembic, furnished with a beak and a receiver.

Some sublimate are required to be in masses as solid and compact as their natures allow. Of this number are camphor, muriate of ammonia, and all the sublimate of mercury. The properest vessels for these sublimate are bottles or matrasses, which are to be sunk more or less deeply in sand, according to the volatility and gravity of the matters that are to be sublimed. In this manner of subliming, the substances, having quitted the bottom of the vessel, adhere to its upper part, and, as this part is low and near the fire, they there suffer a degree of heat sufficient to give them a kind of fusion. The art, therefore, of conducting these sublimate consists in applying such a degree of heat, or in so disposing the sand (that is, making it cover more or less the matrass), that the heat in the upper part of the matrass shall be sufficient to make

the sublimate adhere to the glass, and to give it such a degree of fusion as is necessary to render it compact; but at the same time this heat must not be so great as to force the sublimate through the neck of the matrass, and dissipate it. These conditions are not easily to be attained, especially in great works. Many substances may be reduced into flowers, and sublimed, which require for this purpose a very great heat, with the access of free air and even the contact of coals, and therefore cannot be sublimed in close vessels. Such are most soots or flowers of metals, and even some saline substances. When these sublimate are required, the matters from which they are to be separated must be placed among burning coals in open air; and the flowers are collected in the chimney of the furnace in which the operation is performed. The tutty, calamine, or pompholix, collected in the upper part of furnaces in which ore are smelted, are sublimate of this kind.

SUBLIMATORY (from sublimation). Of or belonging to sublimation, or to the art of subliming.

SUBLIMATORY VESSELS. See CHEMISTRY, Index.

SUBLIMITY, in style. See LANGUAGE, ORATORY, and SIMPLICITY.

SUBLINGUAL, *adj.* Fr. *sublingual*; Lat. *sub* and *lingua*. Placed under the tongue.

Those subliming humours should be intercepted, before they mount to the head by *sublingual* pills.

Harvey.

SUBLINGUAL ARTERY OF SUBLINGUAL GLANDS. See ANATOMY.

SUBLUNAR, *adj.* } Fr. *sublunaire*; Lat. *sub* and *luna*. Situated beneath the moon; earthly; terrestrial; of this world.

Dull *sublunary* lovers! love,
Whose soul is sense, cannot admit
Of absence, 'cause it doth remove
The thing which elemented it. *Donne.*

Through seas of knowledge we our course advance,
Discovering still new worlds of ignorance;
And these discoveries make us all confess
That *sublunary* science is but guess. *Denham.*

Night measured, with her shadowy cone,
Half way up hill this vast *sublunar* vault. *Milton.*

The celestial bodies above the moon, being not subject to chance, remain in perpetual order, while all things *sublunary* are subject to change.

Dryden's Dufresnoy.

Ovid had warned her to beware
Of strolling gods, whose usual trade is,
Under pretence of taking air,
To pick up *sublunary* ladies. *Swift*

The fair philosopher to Rowley flies,
Where in a box the whole creation lies;
She sees the planets in their turns advance,
And scorns, Poitier, this *sublunary* dance. *Young.*

SUBMARINE, *adj.* Lat. *sub* and *mare*. Lying or acting under the sea.

This contrivance may seem difficult, because these *submarine* navigators will want winds and tides for motion, and the sight of the heavens for direction.

Wilkins

Not only the herbaceous and woody *submarine* plants, but also the lithophata, affect this manner of growing, as I observed in corals.

Ray on the Creation

Z

SUBMERGE', v. a. } Fr. *submerger*; Lat. **SUBMER'SION, n. s.** } *submergo*. To drown; to put under water: act or state of drowning.
So half my Egypt was *submerged*, and made
A cistern for scaled snakes.

Shakspeare. Antony and Cleopatra.

The great Atlantick island is mentioned in Plato's *Timaus*, almost contiguous to the western parts of Spain and Africa, yet wholly swallowed up by that ocean; which, if true, might afford a passage from Africa to America by land before that *submersion*.

Hale's Origin of Mankind.

SUBMIN'ISTER, v. a. } Lat. *subministro*.
SUBMIN'ISTRATE. } To supply; to afford.

A word not much in use.

Nothing *subministrates* apter matter to be converted into pestilent seminaries than steams of nasty folks.

Harvey.

Some things have been discovered, not only by the industry of mankind, but even the inferior animals have *subministered* unto man the invention of many things, natural, artificial, and medicinal.

Hale's Origin of Mankind.

Passions, as fire and water, are good servants, but bad masters, and *subminister* to the best and worst purposes.

L'Estrange.

SUBMISS', adj. } Lat. *submissus*. Hum-
SUBMISS'ION, n. s. } ble; submissive; ob-
SUBMISS'IVE, adj. } sequious: submissive
SUBMISS'IVELY, adv. } is the more common
SUBMISS'IVENESS, n. s. } adjective of the same
SUBMISS'LY, adv. } meaning: all the deri-
vatives correspond.

Submission, dauphin! 'tis a mere French word;
We English warriors wot not what it means.

Shakspeare.

Be not as extreme in *submission* as in offence. *Id.*
On what *submissive* message art thou sent? *Id.*

King James, mollified by the bishop's *submit* and eloquent letters, wrote back, that though he were in part moved by his letters, yet he should not be fully satisfied except he spake with him.

Bacon's Henry VII.

If thou dost sin in wine and wantonness,
Boast not thereof, nor make thy shame thy glory;
F frailty gets pardon by *submissiveness*,
But he that boasts shuts that out of his story;
He makes flat war with God, and doth defy,
With his poor clod of earth, the spacious sky.

Herbert.

Humility consists not in wearing mean cloaths,
and going softly and *submissly*, but in mean opinion
of thyself.

Taylor.

Rejoicing, but with awe,
In adoration at his feet I fell

Submit: he reared me. *Milton.*

Her at his feet *submissive* in distress

He thus with peaceful words upraised. *Id.*

No duty in religion is more justly required by God
Almighty, than a perfect *submission* to his will in all
things. *Temple.*

The goddess,
Soft in her tone, *submissively* replies.

Dryden's Æneid.

Sudden from the golden throne
With a *submissive* step I hasted down;
The glowing garland from my hair I took,
Love in my heart, obedience in my look. *Prior.*

But speech even there *submissively* withdraws
From rights of subjects, and the poor man's cause;
Then pompous silence reigns, and stills the noisy
laws. *Pope.*

Great prince, by that *submission* you'll gain more
Than e'er your haughty courage won before.

Halifax.

SUBMIT', v. a. & v. n. Fr. *soumettre*; Lat. *submitto*. To let down; sink; subject: be sub-
ject.

Return to thy mistress, and *submit* thyself under
her hands. *Genesis xvi. 9.*

To thy husband's will

Thine shall *submit*: he over thee shall rule. *Milton.*

Will ye *submit* your neck and chuse to bend

The supple knee? *Id.*

Sometimes the hill *submits* itself a while

In small descents, which do its height beguile;

And sometimes mounts, but so as billows play,

Whose rise not hinders but makes short our way.

Dryden.

Our religion requires from us not only to forego
pleasure, but to *submit* to pain, disgrace, and even
death. *Rogers.*

Whether the condition of the clergy be able to
bear a heavy burden is *submitted* to the house.

Swift.

SUBMONTORIUM, an ancient town of
Germany, in Vindelicia: now called Augsburg.

SUBMULTIPLE, in geometry &c., coincides
with an aliquot part.

SUBMULTIPLE RATIO is that between the quan-
tity contained and the quantity containing. Thus
the ratio of 3 to 21 is submultiple. In both
cases submultiple is the reverse of multiple: 21,
e. gr. being a multiple of 3, and the ratio of 21
to 3 a multiple ratio.

SUBNORMAL (Latin, *sub* and *norma*, a
rule). Belonging to that point in the axis of a
curvilinear space which is intersected by a per-
pendicular to a tangent drawn from any given
point in the curve.

SUBNORMAL, the perpendicular to the tangent
of a curve intercepting the axis.

SUBOCTAVE, adj. } Lat. *sub* and *octavus*,
SUBOC'TUPLE. } and octuple. Contain-
ing one part of eight.

As one of these under pulleys abates half of that
heaviness of the weight, and causes the power to be
in a subduple proportion: so two of them abate half
of that which remains, and cause a subquadruple
proportion, three a sextuple, four a suboctuple.

Wilkins's Mathematical Magick.

Had they erected the cube of a foot for their prin-
cipal concave, and geometrically taken its *suboctave*,
the congius, from the cube of half a foot, they would
have divided the congius into eight parts, each of
which would have been regularly the cube of a quar-
ter foot, their well-known palm: this is the course
taken for our gallon, which has the pint for its *sub-
octave*.

Arbuthnot on Coins.

SUBOR'DINACY, n. s. } Lat. *sub* and *ordi-
SUBOR'DINACY. } natus. The state
SUBOR'DINATE, adj. & v. a. } of being subject;
SUBOR'DINATELY, adv. } series of subordi-
SUBORDINA'TION, n. s. } nation: inferior in
order, nature, dignity, or power: to make so: the
adverb and noun substantive corresponding.*

The two armies were assigned to the leading of
two generals, rather courtiers than martial men, yet
assisted with *subordinate* commanders of great ex-
perience. *Bacon.*

If I have *subordinated* picture and sculpture to ar-
chitecture, as their mistress, so there are other in-
ferior arts *subordinate* to them. *Wotton.*

It being the highest step of ill, to which all others
subordinately tend, one would think it could be capa-
ble of no improvement. *Decay of Piety.*

The natural creatures having a local *subordination*, the rational having a political, and sometimes a sacred.

His next *subordinate*

Awakening, thus to him in secret spake. *Milton.*

The *subordinancy* of the government changing hands so often, makes an unsteadiness in the pursuit of the public interests. *Temple.*

Nor can a council national decide,
But with *subordination* to her guide. *Dryden.*

It was *subordinate*, not enslaved, to the understanding; not as a servant to a master, but as a queen to her king, who acknowledges a subjection, yet retains a majesty. *South.*

Whether dark presages of the night proceed from any latent power of the soul during her abstraction, or from any operation of *subordinate* spirits, has been a dispute. *Addison.*

Pursuing the imagination through all its extravagancies is no improper method of correcting, and bringing it to act in *subordinacy* to reason. *Spectator.*

These carry such plain characters of disagreement or affinity, that the several kinds and *subordinate* species of each are easily distinguished. *Woodward.*

If we would suppose a ministry, where every single person was of distinguished piety, and all great officers of state and law diligent in chusing persons who in their several *subordinations* would be obliged to follow the examples of their superiors, the empire of religion would be soon destroyed. *Swift.*

SUBORDINARIES. See **HERALDRY.**

SUBORN, *v. a.* } Fr. *subornner*; Lat.

SUBORNATION, *n. s.* } *suborno.* To procure privately; procure by secret collusion, or indirectly: the noun substantive corresponding.

Thomas earl of Desmond was through false *subordination* of the queen of Edward IV. brought to his death at Tredah most unjustly. *Spenser on Ireland.*

His judges were the self-same men by whom his accusers were *suborned.* *Hooker.*

Fond wretch! thou knowest not what thou speakest,
Or else thou art *suborned* against his honour
In hateful practice. *Shakspeare.*

You set the crown

Upon the head of this forgetful man,
And for his sake wear the detested blot
Of murderous *subornation.* *Id. Henry IV.*

Reason may meet

Some specious object, by the foe *suborned,*
And fall into deception. *Milton.*

His artful bosom heaves dissembled sighs;
And tears *suborned* fall dropping from his eyes. *Prior.*

Behold

Those who by lingering sickness lose their breath,
And those who by despair *suborn* their death. *Dryden.*

The fear of punishment in this life will preserve men from few vices, since some of the blackest often prove the surest steps to favour; such as ingratitude, hypocrisy, treachery, and *subornation.* *Swift.*

SUBORNATION, in English law, a secret, underground, preparing, instructing, or bringing in a false witness; and hence subornation of perjury is the preparing or corrupt alluring to perjury. The punishment for the crime was formerly death, then banishment or cutting out the tongue, afterwards forfeiture of goods; and it is now a fine and imprisonment, and never more to be received as evidence. The stat. 2 Geo. II. c. 25. superadded a power for the court to order the offender to be sent to the house of correction

for a term not exceeding seven years, or be transported for the same period.

SUBPENA, in law, is a writ whereby common persons are called into chancery, in such cases where the common law hath provided no ordinary remedy: and the name of it proceeds from the words therein, which charge the party called to appear at the day and place assigned, sub pœna centum librarum, &c. The *subpœna* is the leading process in the court of equity; and by statute, when a bill is filed against any person, process of *subpœna* shall be taken out to oblige the defendant to appear and answer the bill, &c.

SUBPENA AD TESTIFICANDUM, a writ or process to bring in witnesses to give their testimony. If a witness on being served with this process does not appear, the court will issue an attachment against him; or a party, plaintiff or defendant, injured by his non-attendance, may maintain an action against the witness. See Blackstone's Commentaries, vol. III. p. 369.

SUBPENA IN EQUITY, a process in equity, calling on a defendant to appear and answer to the complainant's bill. See stat. 5 Geo. II. c. 25, which enacts that where the party cannot be found to be served with a *subpœna*, and absconds (as is believed) to avoid being served, a day shall be appointed him to appear to the bill of the plaintiff; which is to be inserted in the London Gazette, read in the parish church where the defendant last lived, and fixed up at the Royal Exchange: and, if the defendant doth not appear upon that day, the bill shall be taken pro confesso.

SUBQUADRUPLE, *adj.* Sub and quadruple. Containing one part of four.

As one of these under pulleys abates half that heaviness the weight hath in itself, and causes the power to be in a subduple proportion unto it, so two of them abate half of that which remains, and cause a *subquadruple* proportion.

Wilkins's Mathematical Magick.

SUBQUINTUPLE, *adj.* Sub and quintuple. Containing one part of five.

If unto the lower pulley there were added another, then the power would be unto the weight in a *subquintuple* proportion.

Wilkins's Mathematical Magick.

SUBROGATION, or **SURROGATION**, in the civil law, the act of substituting a person, in the place, and entitling him to the rights of another. In its general sense, subrogation implies a succession of any kind, whether of a person to a person, or of a person to a thing. There are two kinds of subrogation: the one conventional, the other legal. Conventional subrogation is a contract whereby a creditor transfers his debt, with all appurtenances thereof, to the profit of a third person. Legal subrogation is that which the law makes in favor of a person who discharges an antecedent creditor; in which case there is a legal translation of all rights of the ancient creditor to the person of the new one.

SUBSALT, a term first used by Dr. Pearson for a salt having an excess of base beyond what is requisite for saturating the acid, as supersalt is one with an excess of the acid. The sulphate of potash is the neutral compound of sulphuric

acid and potash; subsulphate of potash a compound of the same ingredients, in which there is an excess of base; supersulphate of potash, a compound of the same acid and the same base, in which there is an excess of acid.

SUBSCRIBE, *v. a. & v. n.* } *Fr. souscrire;*
 SUBSCRIBER, *n. s.* } *Lat. subscribo.* To
 SUBSCRIPTION. } give consent to by
 underwriting the name; attest by writing; submit: give consent: both the noun substantives corresponding.

Osius, with whose hand the Nicene creed was set down, and framed for the whole Christian world to *subscribe* unto, so far yielded in the end, as even with the same hand to ratify the Arians' confession.

Their particular testimony ought to be better credited than some other *subscribed* with an hundred hands.

The king gone to-night! *subscribed* his power!
 Confined to exhibition! all is gone. *Shakspeare.*

Advise thee what is to be done,
 And we will all *subscribe* to thy advice. *Id.*

I tax not you, you elements, with unkindness;
 I never gave you kingdom, called you children;
 You owe me no *subscription*. *Id. King Lear.*

The man asked, Are ye Christians? We answered we were; fearing the less because of the cross we had seen in the *subscription*. *Bacon.*

They united by *subscribing* a covenant, which they pretended to be no other than had been *subscribed* in the reign of king James, and that his majesty himself had *subscribed* it; by which imposition people of all degrees engaged themselves in it. *Clarendon.*

So spake much humbled Eve; but fate
Subscribed not: nature first gave signs, impressed
 On bird, beast, air. *Milton's Paradise Lost.*

The reader sees the names of those persons by whom this letter is *subscribed*. *Addison.*

The work he plied;
 Stocks and *subscriptions* pour on every side. *Pope.*

Let a pamphlet come out upon a demand in a proper juncture, every one of the party who can spare a shilling shall be a *subscriber*. *Swift.*

SUBSCRIPTION, in general, signifies the signature put at the bottom of a letter, writing, or instrument. In commerce, it is used for the share or interest which particular persons take in a public stock or a trading company, by writing their names, and the shares they require, in the books or register thereof.

SUBSCRIPTION, in the commerce of books, signifies an engagement to take a certain number of copies of a book intended to be printed, and a reciprocal obligation of the bookseller or publisher to deliver the said copies on certain terms. These subscriptions, which had their rise in England about the middle of the last century, were lately very frequent in France and Holland, and are now very common among ourselves.

SUBSCRIPTION TO ARTICLES OF FAITH is a written solemn declaration of the subscriber's assent, and is governed, according to archdeacon Paley, by the same rule of interpretation with oaths;—which rule is the 'animus imponentis.' The enquiry, therefore, concerning subscription will be, 'quis imposuit, et quo animo.' The bishop who receives the subscription, says this ingenious writer, is not the imposer, any more than the cryer of a court, who administers the oath to the jury and witnesses,

is the person that imposes it; nor consequently is the private opinion or interpretation of the bishop of any signification to the subscriber, one way or other. The compilers of the thirty-nine articles are not to be considered as the imposers of subscription, any more than the framer or drawer up of a law is the person that enacts it. The legislature of the 13th Eliz. is the imposer, whose intention the subscriber is bound to satisfy. They who contend that nothing less can justify subscription to the thirty-nine articles, than the actual belief of each and every separate proposition contained in them, must suppose that the legislature expected the consent of 10,000 men, in perpetual succession, not to one controverted proposition, but to many hundreds. It is difficult to conceive how this could be expected by any, who observed the incurable diversity of human opinion upon all subjects short of demonstration. If the authors of the law did not intend this, what did they intend? Our author replies to this question that they intended to exclude from offices in the church, 1. All abettors of popery; 2. Anabaptists, who were at that time a powerful party on the continent; and, 3. The Puritans, who were hostile to an episcopal constitution; and in general the members of such leading sects or foreign establishments, as threatened to overthrow our own. Whoever, he says, finds himself comprehended within these descriptions, ought not to subscribe. For the general reasons upon which he justifies the imposition of this test on the teachers of religion, we must refer to his Moral Philosophy; where it will appear that this writer seems to intimate, that our articles of faith might be converted into articles of peace; and acknowledges that subscriptions perpetuate the proscription of sects and tenets, from which any danger has long ceased to be apprehended. The cases in which subscription to the thirty-nine articles is required are, those of clergy officiating in the church, and entitled to its preferments and emoluments, and of school-masters, of young men in the university of Oxford at the time of their matriculation; and at Cambridge all degrees in arts, law, physic, music, and divinity, are guarded by subscription, nor are any admitted to their first degree of bachelor of arts without a *bonâ fide* subscription, i. e. 'I, A. B., do declare that I am *bonâ fide* a member of the church of England as by law established.'

We must here, however, observe that the three articles contained in the thirty-sixth canon are those that are subscribed at Cambridge for a bachelor of divinity's degree, and for a doctor's in any faculty, divinity, law, or physic. They include all the thirty-nine articles, and are as follow:—1. That the king's majesty, under God, is the only supreme governor of the realm and all other his highness's dominions and countries, as well in spiritual or ecclesiastical things or causes, as temporal, and that no foreign prince, person, prelate, or potentate hath, or ought to have, any jurisdiction, ecclesiastical or spiritual, within his majesty's said realms, dominions, and countries. 2. That the book of common prayer, and of ordering of bishops, priests, and deacons, containeth nothing in it contrary to the word of

God; and that it may lawfully be used; and that he himself will use the form in the said book prescribed in public prayer, and administration of the sacraments, and no other. 3. That he alloweth the book of articles agreed upon by the archbishops, and bishops of both provinces, and the whole clergy in the convocation, holden at London in the year 1562: and that he acknowledgeth all, and every, the articles therein contained (being in number thirty-nine, besides the ratification) to be agreeable to the word of God. We whose names are underwritten do willingly, and ex animo, subscribe to the three articles before mentioned, and to all things in them contained.—Excerpt. e Stat. Acad. Cantab. p. 25.

Many persons who think highly of archdeacon Paley's judgment and liberality, and some who are inclined to interpret subscription with the utmost latitude, are not satisfied with his statement of the intention with which the articles were formed, and subscription to them enjoined. The truth of the case seems to be that the compilers of the articles considered them as comprehending scriptural doctrines, generally believed at the time when they were drawn up, and which they thought no one could reasonably dispute; and that they were authoritatively enforced with a view of preventing diversity of opinion. This will appear if we take a cursory view of the manner in which they were introduced and established. Soon after the Reformation, when dissensions and separations took place among the reformed churches, particularly in Poland, Hungary, and Transylvania, and the Catholics charged these differences and dissensions upon the principles of the reformed, their leaders made attempts for vindicating themselves from the charge. Accordingly they determined to make a public declaration of their principles; they drew up public confessions, and their teachers subscribed a profession of uniformity. A diet was held at Augsburg, in the year 1530, under Charles V., and there an explicit confession, confirmed by the leaders of the several churches, received its birth. In process of time other churches followed the example, and the faith of eleven Protestant churches was comprehended in the Harmony, drawn up by the Belgic and Gallican churches, A. D. 1581. The Book of Concord among the Remonstrants in Holland, and the Corpus Confessionum, which appeared at Geneva in the year 1612, were productions of a similar kind, and formed for like purposes. In England measures of the same tendency were adopted. After Henry VIII. assumed the supremacy of the church, he proceeded, in the exercise of his newly acquired authority, to appoint six articles, ordaining, among other enactments, 'that all bishops and ministers were to believe the whole bible, the three creeds, viz. the Apostles', the Nicene, and the Athanasian, and interpret all things according to them and in the same words.' In the preface it is said, 'they are to maintain unity and concord in opinion.' In the reign of Edward VI. Cranmer and others remonstrated against these articles, and they were repealed; but forty-two articles were published 'for the avoiding of diversity of opinion, and the

gaining of true consent, touching true religion. In queen Elizabeth's reign eleven articles were set out by order of the metropolitans, and the rest of the bishops, 'for the unity of doctrine, to be holden by all parsons, vicars, and curates, as well in testification of their common consent in the said doctrine, as to the stopping of the mouths of those who go about to slander the ministers of the church for diversity of judgment.' Some time after all of them were surveyed, and at length comprised within a system of thirty-nine articles. These articles were again ratified by James I., according to the form commonly prefixed to the book of articles of queen Elizabeth; in which, among other things, are these words, 'that the articles of the church of England (which have been allowed and authorised heretofore, and which our clergy have generally subscribed unto) do contain the true doctrine of the church of England, agreeable to God's word; which we do therefore ratify and confirm, requiring all our loving subjects to continue in the uniform profession thereof, and prohibiting the least difference from the said articles, &c.' It is added, after an assertion 'that we are supreme governor of the church of England,' and the recital of some other particular observations relating to these articles, 'that no man hereafter shall either print or preach to draw the article aside any way, but shall submit to it in the plain and full meaning thereof, and shall not put his own sense or comment to be the meaning of the articles, but shall take it in the literal and grammatical sense. That if any public reader in either of our universities, or any head or master of a college, or any other person respectively in either of them, shall affix any sense to any article, or shall publicly read, determine, or hold any public disputation, or suffer any such to be held either way, in either the universities or colleges respectively; or if any divine in the universities shall preach or print any thing either way, other than is already established in convocation with our royal assent; he or they the offenders shall be liable to our displeasure, and the church's censure in our commission ecclesiastical, as well as any other; and we will see there shall be due execution upon them.'

By 13 Eliz. c. 12, none shall be admitted to the order of deacon, unless he shall first subscribe to the said articles. And, by the same statute none shall be made minister, or permitted to preach or administer the sacraments, unless he first bring to the bishop of that diocese, from men known to the bishop to be of sound religion, a testimonial of his professing the doctrine expressed in the said articles, nor unless he be able to answer and render to the ordinary an account of his faith in Latin, according to the said articles, or have special gift or ability to be a preacher; nor unless he shall first subscribe to the said articles.

By the thirty-sixth canon, no person shall be received into the ministry, nor either by institution or collation admitted to any ecclesiastical living, nor suffered to preach, catechise, or to be a lecturer or reader of divinity in either university, or in any cathedral or collegiate church, city, or market town, parish-church, chapel, or

in any other place, except he shall first subscribe to this article following: viz. 'That he alloweth the book of articles of religion agreed upon by the archbishops and bishops of both provinces, and the whole clergy in the convocation holden at London, in the year of our Lord God 1562; and that he acknowledgeth all and every the articles therein contained, being in number nine-and-thirty, besides the ratification, to be agreeable to the word of God.' And by the statute of the 13 Eliz., c. 12, no person shall be admitted to any benefice with cure, except he shall first have subscribed the said articles in the presence of the ordinary; and all admissions to benefices of any person contrary to this act, and all dispensations, qualifications, and licenses to the contrary, shall be merely void in law, as if they never were.

The 13 & 14 Car. II., c. 4, require subscription to the thirty-nine articles mentioned in the 13th Eliz. c. 12, and a declaration of unfeigned assent and consent unto, and approbation of them, under certain express penalties. It has been observed, however, that by the 13 Eliz. c. 12, subscription is enjoined to those articles which only concern the confession of the true Christian faith, and the doctrine of the sacraments; and that by 14 Car. II. the articles to be subscribed are the articles mentioned in the preceding statute: the limiting clause, therefore, being still in force, there is no act of the legislature imposing the subscription to all the thirty-nine. Such is the opinion of archdeacon Blackburne and Mr. Selden, but others are of a different opinion. We shall here merely remark that the origin of the act of uniformity under Charles II., and various clauses in the act itself, suppose the reception of the disciplinarian as well as the doctrinal and sacramental articles, and that the doctors of the church do actually impose them all.

By those who are acquainted with the history of the times under consideration, and with the sentiments and character of the compilers and imposers of the articles, it must, as it has been conceived, be allowed that the notion of diversity of judgment never entered into the minds of the English reformers; they supposed that the Scriptures had but one meaning, and with an excess of confidence imagined that they were in possession of the truth. In confirmation of this it has been urged that when the Harmony of Confessions was published, among those of other reformed churches, that of the church of England appeared. So that bishop Burnet, though disposed on other occasions to a liberality of interpretation, and though he left his dying testimony against the hard injunction of subscription (Conclusion of his History, vol. ii. p. 634, fol. ed.), ingenuously confesses in his History of the Reformation (vol. ii. p. 169), that the thirty-nine articles were something more than articles of peace, and adds, 'that the men who subscribed them, when they were first set out, did either believe them to be true, or else they did grossly prevaricate.' The bishop's opinion seems to have remained unaltered; for, when his Exposition was about to be published, bishop Williams strongly recommended that they might be con-

sidered only as articles of peace. Upon which the late judge Burnet, mentioning this incident in his father's life, observes 'that there might, perhaps, be reason to wish that they had been only imposed as such; but there was nothing in our constitution to warrant an expositor in giving that sense to them.' Those who respect the opinion of these two able judges, the one of the original intention of the church, the other of the point of law, cannot consistently contend for the pacific sense of subscription. According to the intent of the first subscriptions, maintained by the bishop in his Hist. Reform. above-cited, he could no more give the subscribers of the present age the privilege of availing themselves of different grammatical terms, than he could allow them to consider the articles as articles of peace. Did not the royal declaration prefixed to them, to which we have already referred, and never invalidated by any act of the legislature, preclude a latitude of subscription? The articles were to be subscribed 'ex animo, in the literal and grammatical sense;' and, as this declaration has been continued in every succeeding reign, does it not seem to imply that uniformity is still demanded? We can easily conceive, however, that men of as great integrity as learning, may think themselves warranted in subscribing with greater latitude. Some, as we have seen, have been desirous of considering the articles as articles of peace, and not of faith: and others, again, may reconcile themselves to subscription on different principles. Some have felt the grievance, and have applied (unsuccessfully indeed) to the legislature for relief. Others, who had once subscribed, have declined preferment in the church, because they could not conscientiously renew their subscription: and others have actually surrendered their connexion with it. For a further account of the sentiments and reasonings of different writers, for and against subscription, we refer to archdeacon Blackburne's Confessional.

SUBSEPTUPLE. Lat. *sub* and *septuplus*. Containing one of seven parts.

If unto this lower pulley there were added another, then the power would be unto the weight in a subseptuple proportion; if a third, a *subseptuple*.

Wilkins.

SUBSEQUENT, adj. } Fr. *subsequent*; Lat. *sub* and *sequens*.
SUBSEQUENCE, n. s. } *subsequens*. Improperly pronounced
SUBSEQUENTLY, adv. } long in the second syllable by Shakspeare. Following in train; not preceding: the noun substantive and adverb corresponding.

In such indexes, although small pricks To their *subsequent* volumes, there is seen The baby figure of the giant mass Of things to come at large.

Shakspeare. Troilus and Cressida.

The *subsequent* words came on before the precedent vanish.

Bacon.

By this faculty we can take notice of the order of precedence and *subsequence* in which they are past.

Crew.

To men in governing most things fall out accidentally, and come not into any compliance with their preconceived ends: but they are forced to comply *subsequently*, and to strike in with things as they fall out, by postliminious after-applications of them to their purposes.

South.

Why does each consenting sign
With prudent harmony combine
In turns to move, and subsequent appear
To gird the globe and regulate the year? *Prior.*

This article is introduced as subsequent to the treaty of Munster, made about 1646, when England was in the utmost confusion. *Swift.*

SUBSERVE, *v. a.* } Lat. *subservio*. To
SUBSERVIENT, *n. s.* } serve in subordination;
SUBSERVIENT, *adj.* } to serve instrumentally;
the derivatives corresponding.

Not made to rule
But to *subserve* where wisdom bears command. *Milton.*

There is an immediate and agd subservience of the spirits to the empire of the soul.

Hale's Origin of Manhood.
It is a greater credit to know the ways of captivat-
ing nature, and making her *subserve* our purposes,
than to have learned all the intrigues of policy. *Giannini.*

Hammond had an incredible dexterity, scarce ever
reading any thing which he did not make *subservient*
in one kind or other. *Fell.*

Philosophers and common heathens believed one
God, to whom all things are referred; but under this
God they worshipped many inferior and *subservient*
gods. *Stillingfleet.*

Wicked spirits may by their cunning carry farther
in a seeming confederacy or *subserviency* to the designs
of a good angel. *Dryden.*

The memory hath no special part of the brain de-
voted to its own service, but uses all those parts
which *subserve* our sensations, as well as our train-
ing powers. *Wheat.*

Sense is *subservient* unto fancy, fancy unto intellect. *Greaves.*

We are not to consider the word as the body of
God; he is an uniform being, void of organs, mem-
bers, or parts; and they are his creatures, subordi-
nate to him, and *subservient* to his will. *Newton's Opticks.*

We cannot look upon the body, wherein appears
so much fitness, use, and *subserviency* to infinite func-
tions, any otherwise than as the effect of continuance. *Bentley.*

There is a regular subordination and *subserviency*
among all the parts to beneficial ends. *Chevne's Philosophical Principles.*

Most critics, fond of some *subservient* art,
Still make the whole depend upon a part;
They talk of principles, but notions prize,
And all to one loved folly sacrifice. *Pope.*

SUBSEXTUPLE, *adj.* Lat. *sub* and *sextu-*
plus. Containing one part of six.

One of these under pulls abates half of that heav-
iness the weight hath, and causes the power to be in
a subduple proportion unto it, two of them a sub-
quadruple proportion, three a *subsextuple*. *Willkins's Mathematical Magick.*

SUBSIDE, *v. n.* } Lat. *subsido*. To sink;
SUBSIDENCE, *n. s.* } tend downwards. Com-
SUBSIDENCY. } monly used of one part
of a compound merging in the whole: the noun
substantives corresponding.

He shook the sacred honours of his head,
With terror trembled heaven's *subsiding* hill.
And from his shaken curls ambrosial dews distill. *Dryden.*

This gradual *subsidiency* of the abyss would take up
a considerable time. *Burner's Theory.*

This miscellany of bodies being determined to *sub-*
sidiency merely by their different specific gravities, all

those which had the same gravity descend at the
same time. *Woodward.*

By the alternate motion of those air bubbles
whose surfaces are by turns freed from mutual con-
tact, and by a sudden subsidence next again to the
ingress and egress of the air, the liquor is thus far-
ther attenuated. *Flamsteed.*

Now Jove suspects his golden scales of air,
Weights the seas a weight against the sky's main
The doubtful beam long nods from side to side
At length the wags mount up, the beam descends. *Pope.*

SUBSIDY, *n. s.* } Fr. *subside*; Lat. *sub-*
SUBSIDUARY, *adj.* } *diem*. Aid, commonly
such as is given in money; assistance; temporary
aid.

Bitter substances burn the blood, and are a sort of
subsidary food. *Arctand's Medical History.*

They advised the king to send speedy aid, and
with much alacrity granted a great rate of *subsidy*. *Barrow.*

'Tis all the *subsidy* the present age can raise. *Dryden.*

It is a celebrated notion of a patriot that a share
of common should never grant such *subsidy* as is
to paid to the people, lest the nation should be bur-
dened under a burden they did not feel. *Locke.*

SUBSIDY, in law, signifies an aid which is granted
to the king by parliament for the necessary occa-
sions of the kingdom; and it is being granted to
every subject of ability, according to the value
of his lands or goods, and the amount of
some of our statutes, is confounded with that of
customs. See **TAX**.

SUBSIDY, in modern European politics, is a
large sum of money, often amounting to millions,
generously thrown away by the British govern-
ment to certain foreign despots who had them-
selves our allies, to pay them for fighting their
own battles, and who, when they get their own
ends accomplished, commonly make a separate
peace with the enemy, and leave us to the
lurch; nay, sometimes ungratefully turn the fire
against us. By such *subsidies* Britain often
gains much glory, but the profit goes to her
allies, while her national debt still increases. See
the history of Europe for the last century or more.

SUBSIGN, *v. a.* Lat. *subsigno*. To sign
under.

Neither have they seen any deed before the con-
quest, but *subsigned*, with crosses and simple names
without surnames. *Combe.*

SUBSIST, *v. n.* } Fr. *subsister*; Lat. *sub-*
SUBSISTENCE, *n. s.* } *sisto*. To be; have ex-
SUBSISTENT, *adj.* } istence; continue; have
means of living; inhere; subsistence is, that
being; means of support; competence; the ad-
jective corresponding.

The flesh, and the conjunction of the flesh with
God, began both at one instant: his making and
taking to himself our flesh was but one act, so that
in Christ there is no personal *subsistence* but one,
and that from everlasting. *Hobbes.*

Firm we *subsist*, but possible to swerve. *Milton.*

We know as little how the union is dissolved, that
is, the chain of these differing *subsistences* that com-
pound us, as how it first compounded. *Greaves.*

Such as deny spirits *subsistent* without bodies, will
with difficulty affirm the separate existence of the
own. *Brown.*

Not only the things and *substance*, but the very images were of some creatures existing. *Stillingfleet.*

He shone so powerfully upon me, that, like the heat of a Russian summer, he ripened the fruits of poetry in a cold climate; and gave me wherewithal to *subsist* in the long winter which succeeded.

Dryden.

Though the general natures of these qualities are sufficiently distant from one another, yet when they come to *subsist* in particulars, and to be clothed with several accidents, then the discernment is not so easy.

South.

His viceroy could only propose to himself a comfortable *subsistence* out of the plunder of his province.

Addison.

These qualities are not *subsistent* in those bodies, but are operations of fancy begotten in something.

Bentley.

The very foundation was removed, and it was a moral impossibility that the republic could *subsist* any longer.

Swift.

SUBSTANCE, *n. s.* } Fr. *substance*; Lat. }
 SUBSTANTIAL, *adj.* } *substantia*. Being; }
 SUBSTANTIALITY, *n. s.* } something existing; }
 SUBSTANTIALLY, *adv.* } something real; the }
 SUBSTANTIALNESS, *n. s.* } essential part; body; }
 SUBSTANTIALS, *n. s.* } means of life; wealth: }
 SUBSTANTIATE, *v. a.* } substantial and sub- }
 stantially follow these senses: substantiality is reality of existence; materiality; corporeity: substantials, essentials or essential parts: to substantiate, to make to exist; prove valid.

Trials of crimes and titles of right shall be made by verdict of a jury, chosen out of the honest and most *substantial* freeholders.

Spenser on Ireland.

He hath eaten me out of house and home, and hath put all my *substance* into that fat belly of his; but I will have some of it out again.

Shakspeare. Henry IV.

O blessed, blessed night! I am afraid, Being in night, all this is but a dream; Too flattering sweet to be *substantial*.

Shakspeare.

Shadows to-night Have struck more terror to the soul of Richard, Than can the *substance* of ten thousand soldiers Armed all in proof, and led by shallow Richmond.

Id.

When *substantialness* combineth with delightfulness, fulness with fineness, how can the language which consisteth of these sound other than most full of sweetness?

Camden's Remains.

Since then the soul works by herself alone, Springs not from sense, nor humours well agreeing; Her nature is peculiar, and her own;

She is a *substance*, and a perfect being.

Davies.

In degree of *substantialness* next above the Dorique, sustaining the third, and adorning the second story.

Wotton.

Having so *substantially* provided for the north, they promised themselves they should end the war that summer.

Clarendon.

It will serve our turn to comprehend the *substance*, without confining ourselves to scrupulous exactness in form.

Digby.

If happiness be a *substantial* good, Not framed of accidents, nor subject to them, I erred to seek it in a blind revenge.

Denham.

To give thee being, I lent Out of my side to thee, nearest my heart, *Substantial* life.

Milton.

He the future evil shall no less In apprehension than in *substance* feel.

Id.

Substantial doors, Cross-barred and bolted fast, fear no assaults.

Id.

The strength of gods,

And this empyreal *substance*, cannot fail. *Id.*

What creatures there inhabit, of what mould And *substance*?

Id.

In him his Father shone *substantially* expressed.

Id.

Time, as a river, hath brought down to us what is more light and superficial, while things more solid and *substantial* have been immersed.

Glanville.

The laws of this religion would make men, if they would truly observe them, *substantially* religious towards God, chaste and temperate.

Tillotson.

Heroic virtue did his actions guide, And he the *substance*, not the' appearance, chose.

To rescue one such friend he took more pride, Than to destroy whole thousands of such foes.

Dryden.

The difference betwixt the empty vanity of ostentation, and the *substantial* ornaments of virtue.

L'Estrange.

God is no longer to be worshipped and believed in as a God foreshewing and assuring by types, but as a God who has performed the *substance* of what he promised.

Nelso.

The accidental of any act is said to be whatever advenes to the act itself already *substantiated*.

Ayliffe's Parergon.

Although a custom introduced against the *substantials* of an appeal be not valid, as that it should not be appealed to a superior but to an inferior judge, yet a custom may be introduced against the accidentals of an appeal.

Id.

The merchants, and *substantial* citizens, cannot make up more than a hundred thousand families.

Addison on the War.

They are the best epitomes, and let you see with one cast of the eye the *substance* of a hundred pages.

Addison.

Now shine these planets with *substantial* rays? Does innate lustre gild their measured days? Prior:

Between the parts of opaque and coloured bodies are many spaces, either empty or replenished with mediums of other densities; as, water between the tinging corpuscles wherewith any liquor is impregnated, air between the aqueous globules that constitute clouds or mists, and for the most part spaces void of both air and water; but yet perhaps not wholly void of all *substance* between the parts of hard bodies.

Newton.

Observations are the only sure grounds whereon to build a lasting and *substantial* philosophy.

Woodward.

The qualities of plants are more various than those of animal *substances*.

Arbuthnot on Aliments.

There may be a great and constant cough, with an extraordinary discharge of phlegmatick matter, while, notwithstanding, the *substance* of the lungs remains sound.

Blackmore.

If this atheist would have his chance to be a real and *substantial* agent, he is more stupid than the vulgar.

Bentley.

We are destroying many thousand lives, and exhausting our *substance*, but not for our own interest.

Swift.

The sun appears flat like a plate of silver, the moon as big as the sun, and the rainbow a large *substantial* arch in the sky; all which are gross falsehoods.

Watts.

Every being is considered as subsisting in and by itself, and then it is called a *substance*; or it subsists in and by another, and then it is called a mode or manner of being.

Id.

SUBSTANTIAL means also belonging to the nature of *substance*.

SUBSTANTIVE, *n. s.* Fr. *substantif*; Lat. *substantivum*. A noun betokening the thing, not a quality.

He considered how sufficient and *substantive* this land was to maintain itself, without any aid of the foreigner. *Bacon*.

Claudian perpetually closes his sense at the end of a verse, commonly called golden, or two *substantives* and two adjectives, with a verb betwixt them to keep the peace. *Dryden*.

One is obliged to join many particulars in one proposition, because the repetition of the *substantive* verb would be tedious. *Arbutnot*.

SUBSTANTIVE VERB, *ii.* grammar, a verb expressing existence; as I am; to be; to exist. The Latin has four substantive verbs; viz. Sum, fio, forem, and existo.

SUBSTITUTE, *v. a. & n. s.* } Fr. *substituer*,
SUBSTITUTION, *n. s.* } Lat. *substitutus*,
 from *sub* and *statuo*. To put in the place of another; one so placed: the act of substituting, or state of being substituted.

You 've taken up,
 Under the counterfeited zeal of God,
 The subjects of his *substitute*, my father,
 And here upswarmed them. *Shakspeare. Henry IV.*

He did believe
 He was the duke, from *substitution*,
 And executing the' outward face of royalty,
 With all prerogative. *Id. Tempest.*

Nor sal, sulphur, or mercury, can be separated from any perfect metals; for every part, so separated, may easily be reduced into perfect metal without *substitution* of that which chymists imagine to be wanting. *Bacon's Physical Remains.*

Hast thou not made me here thy *substitute*,
 And these inferior far beneath me set? *Milton.*

If a swarthy tongue
 Is underneath his humid palate hung,
 Reject him then, and *substitute* another. *Dryden.*

In the original designs of speaking, a man can *substitute* none for them that can equally conduce to his honour. *Government of the Tongue.*

Providence delegates to the supreme magistrate the same power for the good of men, which that supreme magistrate transfers to those several *substitutes* who act under him. *Addison.*

Some few verses are inserted or *substituted* in the room of others. *Congreve.*

SUBSTRACTION, *n. s.* Fr. *soustraire, soustraction*; Lat. *subtraho*. The act of taking away part from the whole.

I cannot call this piece Tully's nor my own, being much altered not only by the change of the style, but by addition and *substraction*. *Denham.*

SUBSTRACTION and **SUBTRACT** certainly are or ought to be obsolete. They are a vulgar and irregular spelling, totally unauthorised by the original Latin words, *sub* and *traho*. It is absurd to pretend they are derived from the French; for in that case they should be *soustract*, and *soustraction*.

SUBSTRUCTION, *n. s.* Lat. *substructio, substruo*. Underbuilding.

To found our habitation firmly, examine the bed of earth upon which we build, and then the underfillings, or *substruction*, as the ancients call it. *Wotton's Architecture.*

SUBSTYLAR, *adj.* Lat. *sub* and *stylus*. The substylar line is, in dialling, a right line, whereon

the gnomon or style of a dial is erected at right angles with the plane.

Erect the style perpendicularly over the *substylar* line, so as to make an angle with the dial-plane equal to the elevation of the pole of your place. *Morcon's Mechanical Exercises.*

SUBSUL'LORILY, *adv.* Lat. *subsultus*. In a bounding manner; by fits; by starts.

The spirits spread even, and move not *subsultory*, for that will make the parts close and pliant. *Bacon's Natural History.*

SUBTANGENT OF A CURVE, the line that determines the intersection of a tangent with the axis, or that determines the point wherein the tangent cuts the axis prolonged. The tangent, subtangent, and semiordinate, always make a right-angled triangle.

It is a rule in all equations that, if the value of the subtangent comes out positive, the point of intersection of the tangent and axis falls on that side of the ordinate, where the vertex of the curve lines, as in the parabola and paraboloids.

If it come out negative, the point of intersection will fall on the contrary side of the ordinate, in respect of the vertex or beginning of the absciss; as in the hyperbola and hyperbolic figures. And universally, in all paraboliform and hyperbolic figures, the subtangent is equal to the exponent of the power of the ordinate multiplied into the absciss: thus, in the common parabola, whose property is $px = yy$, the subtangent is in length equal to x ; the absciss multiplied by 2, the exponent of the power of yy , the square of the ordinate; that is, it is equal to twice the absciss; and, by the former rule for paraboliform figures, it must be taken above the ordinate in the axis produced.

Thus, also, in one of the cubical paraboloids, where $pxx = yyy$; the length of the subtangent will be $\frac{2}{3}$ of the absciss; and in a parabola of any kind, the general equation being $ax^n = y^{m+n}$, the subtangent is $= \frac{m+n}{n} \times x$, or its ratio to the absciss, is constantly that of $m+n$ to n .

In the parabola the subtangent is double the absciss; and in the logarithmic curve, the subtangent is also a constant quantity.

SUBTENDY, *v. a.* Lat. *sub* and *tendo*. To be extended under.

From Aries rightways draw a line, to end
 In the same round, and let that line *subtend*
 An equal triangle: now since the lines
 Must three times touch the round, and meet three
 signs,
 Where'er they meet in angles, those are trines. *Creech.*

In rectangles and triangles, the square which is made of the side that *subtendeth* the right angle, is equal to the squares which are made of the sides containing the right angle. *Broune.*

SUBTERMANS (Justus), an eminent Flemish painter, born at Antwerp, in 1597. He was famous for history and portraits. In the palace of Florence there is a celebrated painting by him, of the homage made to Ferdinand II. by the Florentine nobles. He died 1681, aged eighty-four.

SUBTERFUGE, *n. s.* Fr. *subterfuge*; Lat. *subter* and *fugio*. A shift; an evasion; a trick.

The king cared not for *subterfuges*, but would stand envy, and appear in any thing that was to his mind. *Bacon.*

Notwithstanding all their sly *subterfuges* and studied evasions, yet the product of all their endeavours is but as the birth of the labouring mountains, wind and emptiness. *Glanville.*

Affect not little shifts and *subterfuges* to avoid the force of an argument. *Watts.*

SUBTERRANEAL, *adj.* } Lat. *sub* and
SUBTERRANEAN, } *terra*; Fr. *sous-*
SUBTERRANEOUS, } *terrine*.
SUBTERRAN, } *terran* or *subter-*
SUBTERRANITY, *n. s.* } *ran*eous or *subter-*
 the word now used. Lying under the earth; placed below the surface: *subterraneity* (obsolete) is a place under ground.

Metals are wholly *subterranean*; whereas plants are part above earth, and part under.

In *subterraneities*, as the fathers of their tribes, are brimstone and mercury. *Bacon's Natural History.*
Id.

The force
 Of *subterranean* wind transports a hill
 Torn from Pelorus, or the shattered side
 Of thundering *Ætna*, whose combustible
 And fueled entrails thence conceiving fire,
 Sublimed with mineral fury, aid the winds. *Milton.*

We commonly consider *subterraneities* not in contemplations sufficiently respective unto the creation. *Broune.*

Alteration proceeded from the change made in the neighbouring *subterranean* parts by that great conflagration. *Boyle.*

Let my soft minutes glide obscurely on,
 Like *subterraneous* streams, unheard, unknown. *Norris.*

This *subterraneous* passage was not at first designed so much for a highway as for a quarry. *Addison.*

Tell by what paths, what *subterranean* ways,
 Back to the fountain's head the sea conveys
 The reflux rivers. *Blackmore.*

Roused within the *subterranean* world,
 The' expanding earthquake unresisted shakes
 Aspiring cities. *Thomson.*

SUBTILE, *adj.* } Fr. *subtile*; Lat.
SUBTILELY, *adv.* } *subtilis*. Often writ-
SUBTIL'ATE, *v. a.* } ten subtle, which
SUBTIL'ATION, *n. s.* } signifies thin; not
SUBTILIZ'ATION, } dense; not gross;
SUBTILIZE, *v. a. & v. n.* } nice; fine; piercing;
SUBTILITY, *n. s.* } hence cunning; art-
SUBTLE, *adj.* } ful; sly; deceitful:
SUBTLELY, *adv.* } both the adverbs cor-
 responding: *subtiliate* and *subtilize* mean to make thin; talk affectedly: the noun substantives corresponding: and *subtily* with subtle, adjective.

A woman, an harlot, and *subtile* of heart. *Proverbs vii. 10.*

Finding force now faint to be,
 He thought grey hairs afforded *subtily*. *Sidney.*

Some *subtle* headed fellow will put some quirk, or devise some evasion, whereof the rest will take hold. *Spenser.*

Shall we think the *subtle*-witted French
 Conj'ners and sorc'ners, that, afraid of him,
 By magick verse have thus contrived his end?
Shakspeare. Henry VI.

Think you this York
 Was not incensed by his *subtle* mother
 To taunt and scorn you? *Id. Richard III.*

Like a bowl upon a *subtle* ground,
 I've tumbled past the throw. *Id. Coriolanus.*

The constitution of the air appeareth more *subtily* by worms in oak-apples than to the sense of man. *Bacon.*

Whatever is invisible, in respect of the fineness of the body, or *subtily* of the motion, is little enquired. *Id.*

But of the clock, which in our breasts we bear,
 The *subtile* motions we forget the while. *Davies.*

How shall we this union well express?
 Nought ties the soul, her *subtily* is such. *Id.*

O *subtile* love, a thousand wiles thou hast
 By humble suit, by service, or by hire,
 To win a maiden's hold. *Fairfax.*

The rudeness and barbarity of savage Indians know not so perfectly to hate all virtues as some men's *subtily*. *King Charles.*

From his eyes the fleeting fair
 Retired, like *subtle* smoke dissolved in air.
Dryden's Georgicks.

Intelligible discourses are spoiled by too much *subtily* in nice divisions. *Locke.*

Chyle, being mixed with the choler and pancreatic juices, is further *subtilized*, and rendered so fluid and penetrant that the thinner and finer part easily finds way in at the straight orifices of the lacteous veins. *Ray on the Creation.*

Body cannot be vital; for, if it be, then is it so either as *subtilized* or organized, moved or endowed with life. *Grew.*

The Arabians were men of a deep and *subtle* wit. *Spratt.*

Bodies, the more of kin they are to spirit in *subtlety*, and refinement, the more spreading and self-diffusive are they. *Norris.*

Pass we the slow disease, and *subtile* pain,
 Which our weak frame is destined to sustain;
 The cruel stone, the cold catarrh. *Prior.*

Deny Des Cart his *subtile* matter,
 You leave him neither fire nor water. *Id.*

The opakest bodies, if *subtily* divided, as metals dissolved in acid menstruums, become perfectly transparent. *Newton.*

Greece did at length a learned race produce,
 Who needful science mocked, and arts of use;
 Mankind with idle *subtilties* embroil,
 And fashion systems with romantic toil. *Blackmore.*

Fluids have their resistances proportional to their densities, so that no *subtilization*, division of parts, or refining, can alter these resistances.

Cheyne's Philosophical Principles.
 In the nice bee, what sense so *subtly* true,
 From pois'nous herbs extracts the healing dew!

They give method, and shed *subtily* upon their author. *Pope.*
Baker.

SUBTILE, in physics, an appellation given to whatever is extremely small, fine, and delicate; such as the animal spirits, the effluvia of odorous bodies, &c., are supposed to be.

SUBTRACT, *v. a.* Lat. *subtractio*. They who derive it from the Latin write *subtract*; those who regard the French original *subtract*; to withdraw part from the rest.

Reducing many things unto charge, which, by confusion, became concealed and *subtracted* from the crown. *Davies.*

What is *subtracted* or subducted out of the extent of the divine perfection, leaves still a quotient infinite. *Hale.*

The same swallow, by the *subtracting* daily of her eggs, laid nineteen successively, and then gave over. *Ray.*

SUBTRACTION, in arithmetic, the second rule, or rather operation, in arithmetic, whereby we deduct a less number from a greater, to learn their precise difference. See **ARITHMETIC**, Index; and **ALGEBRA**.

SUBTRIPLE, *adj.* Fr. *subtriple*; Lat. *sub* and *tripplus*. Containing a third, or one part of three.

The power will be in a *subtriple* proportion to the weight. *Wilkins's Mathematical Magick.*

SUBVENTANEUS, *adj.* Lat. *subventaneus*. Adde; windy

Suitable unto the relation of the mares in Spain, and their *subventaneous* conceptions from the western wind. *Browne.*

SUBVERSE, *v. a.* } Latin *subversus*. To
SUBVERSION, *n. s.* } subvert. Spenser uses
SUBVERSIVE, *adj.* } subverst in the same
sense. The noun substantive and adjective corresponding

These seek *subversion* of thy harmless life.

Shakspeare. Henry VI.

It is far more honourable to suffer, than to prosper in their ruin and *subversion*. *King Charles.*

These things refer to the opening and shutting the abyss, with the dissolution or *subversion* of the earth. *Burnet.*

Laws have been often abused, to the oppression and the *subversion* of that order they were intended to preserve. *Rogers.*

Empires *subversed*, when ruling fate has struck The unalterable hour. *Thomson's Autumn.*

SUBVERT, *v. a.* } Fr. *subvertir*; Lat. *sub-*
SUBVERTER, *n. s.* } *verto*. To overthrow; overturn; turn upside down; destroy: the noun substantive corresponding.

Strive not about words to no purpose but to the *subverting* of the hearers. *2 Tim. ii. 14.*

God, by things deemed weak, *subverts* the worldly strong and worldly wise. *Milton.*

O traitor! worse than Simon was to Troy;
O vile *subverter* of the Gallick reign,
More false than Gano was to Charlemaigne! *Dryden.*

Trees are *subverted* or broken by high winds. *Mortimer.*

They anathematize them as enemies to God, and *subverters* of souls. *Waterland.*

SUBULARIA, rough-leaved alysson, or awlwort, in botany, a genus of plants belonging to the class of tetradynamia, and order of siliculosa, and in the natural order ranging under the thirtieth order, siliculosæ. The silicula is entire and ovate; the valves are ovate, concave, and contrary to the partitions. The style is shorter than the silicula. There is only one species, viz.

S. aquatica, which is a native of Britain. It is about an inch high. The leaves are awl-shaped, and grow in clusters round the root. The stalk is naked, and produces four or five small white flowers growing alternately on short foot-stalks. It flowers under water, whereas most aquatic plants emerge above water at the time of flowering. The author of nature has, however, carefully prevented the tender flower from receiving any injury from the water by making the petals close and form themselves into a kind of arch. This plant grows on the borders of the Highland lakes, in Loch Tay, in Scotland, also in Wales and Ireland.

SUBUR, in ancient geography; 1. a river of Mauntania; 2. a town of Spain.

SUB'URB, *n. s.* } Lat. *suburbium*. A build-
SUBURBAN, *adj.* } ing without the walls of a city; the outer part: inhabiting the suburbs.

There's a trim rabble let in: are all these your faithful friends of the *suburbs*? *Shakspeare. Henry VIII.*

The *suburbs* of my jacket are so gone,
I have not left one skirt to sit upon. *Cleveland.*

When our fortunes are violently changed, our spirits are unchanged, if they always stood in the *suburbs* and expectation of sorrows. *Taylor.*

They on the smoothed plank,
The *suburb* of their straw-built citadel,
Expiate. *Milton.*

Poor clinches the *suburban* muse affords,
And Panton waging harmless war with words. *Dryden.*

Then weds an heiress of *suburban* mould,
Ugly as apes, but well endowed with gold. *Harte.*

SUBWORKER, *n. s.* Sub and worker. Underworker; subordinate helper.

He that governs well leads the blind, but he that teaches gives him eyes: and it is glorious to be a *subworker* to grace, in freeing it from some of the inconveniencies of original sin. *South.*

SUCCEDANEUS, *adj.* Lat. *succedaneus*. Supplying the place of something else.

Nor is *Aetius* strictly to be believed when he prescribeth the stone of the otter as a *succedaneous* unto castaneum. *Brouce.*

I have not discovered the menstruum: I will present a *succedaneous* experiment made with a common liquor. *Boyle.*

SUCCEED, *v. n. & v. a.* } French *succéder*,
SUCCEEDER, *n. s.* } Lat. *succedo*. To follow in order; terminate an undertaking effectually: have a good effect: to follow; prosper: one who follows. See **SUCCESS**.

If thou deal truly, thy doings shall prosperously succeed to thee. *Tob. iv. 6.*

If I were now to die,
'Twere to be most happy; for I fear
My soul hath her consent so absolute,
That not another comfort like to this
Succeeds in unknown fate. *Shakspeare. Othello.*

Nature has so far imprinted it in us, that should the envy of predecessors deny the secret to *succeeders*, they yet would find it out. *Sackling.*

Workmen let it cool by degrees in such relents of nealing heats, lest it should shiver in pieces by a violent *succeeding* of air in the room of the fire. *Digby on Bodies.*

Enjoy till I return
Short pleasures; for long woes are to succeed. *Milton.*

In that place no creature was hurtful unto man; and those destructive effects they now discover *succeeded* the curse, and came in with thorns and briars. *Browne's Vulgar Errors.*

If the father left only daughters, they equally *succeeded* to him in copartnership, without prelation or preference of the elder to a double portion. *Hale.*

They make one man's particular fancies, perhaps failings, confining laws to others, and convey them to their *succeeders*, who afterwards misname all unobsequiousness as presumption. *Boyle.*

Revenge *succeeds* to love, and rage to grief. *Dryden.*

These dull harmless makers of lampoons are yet of dangerous example to the publick: some witty

men may *succeed* to their designs, and, mixing sense with malice, blast the reputation of the most innocent. *Id.*

'Tis almost impossible for poets to *succeed* without ambition : imagination must be raised by a desire of fame to a desire of pleasing. *Id.*

This was impossible for Virgil to imitate, because of the severity of the Roman language : Spenser endeavoured it in Shepherd's Kalendar ; but neither will it *succeed* in English. *Id.*

SUCCESS', *n. s.*
SUCCESS'FUL, *adj.*
SUCCESS'FULLY, *adv.*
SUCCESS'FULNESS, *n. s.*
SUCCESS'ION, *n.*
SUCCESS'IVE, *adj.*
SUCCESS'IVELY, *adv.*
SUCCESS'IVENESS, *n. s.*
SUCCESS'LESS, *adj.*
SUCCESS'OR, *n. s.*

Fr. *succés* ; Latin *successus*. The happy termination of any thing : the adjective, adverb, and noun substantive following corresponding : *succession* is consecutive ; series ; lineage ; order of descendants :

successive, following in order ; inherited by *succession* : the adverb and noun substantive corresponding : *successless*, luckless ; unfortunate : *successor*, he who succeeds.

The *succession* of Moses in prophecies.

Ecclus. xlv. 1.

For good *success* of his hands, he asketh ability to do of him that is most unable. *Wisdom xiii. 19.*

This king-by this queen had a son of tender age, but of great expectation, brought up in the hope of themselves, and a ready acceptance of the inconstant people, as *successor* of his father's crown. *Sidney.*

All the sons of these five brethren reigned
By due *success*, and all their nephews late,
Even thrice eleven descents, the crown retained.

Spenser.

Three sons he left,
All which *successively* by turns did reign.

Faerie Queene.

St. Augustine, having reckoned up a great number of the bishops of Rome, saith, in all this order of *succession* of bishops, there is not one found a Donatist. *Hooker.*

He is too young, yet he looks *successfully*.

Shakspeare.

Cassibelan,
And his *succession*, granted Rome a tribute.

Id. Cymbeline.

It is upon record ? or else reported
Successively from age to age ?

Id. Richard III.

Countrymen,
Plead my *successive* title with your swords.

Shakspeare.

The empire being elective, and not *successive*, the emperors, in being, made profit of their own times.

Raleigh.

These decays in Spain have been occasioned by so long a war with Holland ; but most by two *successions* of inactive princes. *Eacon.*

We that measure times by first and last,

The sight of things *successively* do take,
When God on all at once his view doth cast,

And of all times doth but one instant make.

Davies.

Three with fiery courage he assails,
And each *successive* after other quails,
Still wondering whence so many kings should rise.

Daniel.

An opinion of the *successfulness* of the work is as necessary to found a purpose of undertaking it, as the authority of commands, or the persuasiveness of premises. *Hammond.*

A second colony is sent hither, but as *successful* as the first. *Heylyn.*

The fear of what was to come from an unacknowledged *successor* to the crown, clouded much of that prosperity then, which now shines in chronicle. *Clarendon.*

Perplexed and troubled at his bad *success*
The tempter stood.

Milton.

A long *succession* must ensue ;
And his next son the clouded ark of God
Shall in a glorious temple enshrine.

Id. Paradise Lost.

God hath set
Labour and rest, as day and night, to men
Successive.

Id.

All the notion we have of duration is partly by the *successiveness* of its own operations, and partly by those external measures that it finds in motion. *Hale.*

Not Lemuel's mother with more care
Did counsel or instruct her heir ;
Or teach with more *success* her son
The vices of the time to shun.

Waller.

Every reasonable man cannot but wish me *success* in this attempt, because I undertake the proof of that which it is every man's interest that it should be true. *Tillotson.*

The hopes of thy *successful* love resign. *Dryden.*

What people is so void of common sense,
To vote *succession* from a native prince !

Id.

The surly savage offspring disappear,
And curse the bright *successor* of the year ;
Yet crafty kind with daylight can dispense.

Id.

He observed the illustrious throng,
Their names, their fates, their conduct, and their care,

In peaceful senates and *successful* war.

Id.

Let a cannon-bullet pass through a room, and take with it any limb of a man, it is clear that it must strike *successively* the two sides of the room, touch one part of the flesh first, and another after, and so in *succession*.

Loche.

The Bavarian duke,
Bold champion ! brandishing his Noric blade,
Best tempered steel, *successful* proved in field.

Philips.

God, by reason of his eternal indivisible nature, is by one single act of duration present to all the *successive* portions of time, and all *successively* existing in them. *South.*

They were terrible alarms to persons grown wealthy by a long and *successful* imposture, by persuading the world that men might be honest and happy, though they never mortified any corrupt appetites. *Id.*

Whether a bright *successor*, or the same. *Tate.*

Whilst malice and ingratitude confess,
They've strove for ruin long without *success*.

Garth.

Passion unpitied, and *successful* love,
Plant daggers in my heart.

Addison's Cato

Send the *successive* ills through ages down,
And let each weeping father tell his son.

Prior.

The early hunter
Blesses Diana's hand who leads him safe
O'er hanging cliffs ; who spreads his net *successful*,
And guides the arrow through the panther's heart.

Id.

I inclined the paper to the rays very obliquely, that the most refrangible rays might be more copiously reflected than the rest, and the whiteness at length changed *successively* into blue, indigo, and violet. *Newton's Opticks.*

This is the most proper and most *successful* season to meet and attack the advancing enemy.

Blackmore.

The rule of imitating God can never be *successfully* proposed but upon Christian principles; such as that this world is a place not of rest, but of discipline.

Atterbury.

Military *successes*, above all others, elevate the minds of a people. *Id.*

Gas sulphuris may be given with *success* in any disease of the lungs. *Arbuthnot on Diet.*

Bleeding, when the expectoration goes on *successfully*, suppresseth it. *Id.*

The descendants of Alexander's *successors* cultivated navigation in some lesser degree. *Arbuthnot.*

We have a tradition coming down to us from our fathers; a kind of inheritance *successively* conveyed to us by the primitive saints from the apostles themselves. *Waterland.*

No such motion of the same atom can be all of it existent at once: it must needs be made gradually and *successively*, both as to place and time; seeing that body cannot at the same instant be in more places than one. *Bentley's Sermons.*

Successless all her soft caresses prove,

To banish from his breast his country's love. *Pope.*

A reformation *successfully* carried on in this great town would in time spread itself over the whole kingdom. *Swift.*

SUCCESS, or GOOD SUCCESS BAY, a bay on the south-east coast of Terra del Fuego, in the straits of Le Maire. On the mountains inland Mr. Banks and Dr. Solander found many new Alpine plants, unknown in Europe: but the cold was so intense that the latter had well nigh fallen a sacrifice to its severity in the midst of summer. Dr. Solander, who had more than once crossed the mountains which divide Sweden from Norway, well knew that extreme cold, especially when joined with fatigue, produces a torpor and sleepiness that are almost irresistible: he therefore conjured the company to keep moving whatever pain it might cost them, and whatever relief they might be promised by an inclination to rest. 'Whosoever sits down,' says he, 'will sleep; and whosoever sleeps will wake no more.' The Dr. himself, however, was the first who found the inclination, against which he had warned others, irresistible; and insisted upon being suffered to lie down. Mr. Banks intreated and remonstrated in vain; down he lay upon the ground, though it was covered with snow, and it was with great difficulty that his friend kept him from sleeping. Richmond also, one of the black servants, began to linger, having suffered from the cold in the same manner as the doctor. Mr. Banks, therefore, sent five of the company, among whom was Mr. Buchan, forward to get a fire ready at the first convenient place they could find, and himself and four others remained with the doctor and Richmond, whom, partly by persuasion and intreaty, and partly by force, they brought on, till they both declared they could go no farther. Mr. Banks had recourse to intreaty and expostulation, but they produced no effect. When Richmond was told that if he did not go now he would in a short time be frozen to death, he answered that he desired nothing but to lie down and die. The doctor did not so explicitly renounce his life; he said he was willing to go on, but that he must first take some sleep, though he had before told the company that to sleep was to perish. Mr. Banks and the rest found it impossible to carry them, and there being

no remedy, they were suffered to sit down, being partly supported by the bushes, and in a few minutes they fell into a profound sleep. Soon after, some of the people who had been sent forward returned with the welcome news that a fire was kindled about a quarter of a mile farther on the way. Mr. Banks then endeavoured to wake Dr. Solander, and happily succeeded; but though he had not slept five minutes, he had almost lost the use of his limbs, and the muscles were so shrunk that his shoes fell from his feet; he consented to go forward, with such assistance as could be given him, but no attempts to relieve poor Richmond were successful, who, with a seaman sent to his relief, died. Long. 65° 27' W., lat. 54° 50' S.

SUCCESSION, in law. See DESCENT, INHERITANCE, and LAW.

SUCCESSION, in metaphysics, the idea which we get by reflecting on the ideas which follow one another in our mind; and from the succession of ideas we get the idea of time. See METAPHYSICS.

SUCCESSION OF COLONELS. A particular part of the official army list is so called. The dates of the several appointments are therein specified, together with the numbers and facings of the different regiments.

A commission in Succession, a commission in which an individual has an inherent property from having purchased it, or raised men; or which, through interest, he is at liberty to sell to the best advantage, provided it does not go in the regiment; in which case no more than the king's regulation can be taken.

SUCCESSION TO THE CROWN OF ENGLAND. See HEREDITARY RIGHT. From the days of Egbert, the first sole monarch of England, even to the present, the four cardinal maxims mentioned in that article have ever been held constitutional canons of succession. It is true, as Sir William Blackstone observes, this succession, through fraud or force, or sometimes through necessity, when in hostile times the crown descended on a minor or the like, has been very frequently suspended; but has generally at last returned back into the old hereditary channel, though sometimes a very considerable period has intervened. And even in those instances where this succession has been violated, the crown has ever been looked on as hereditary in the wearer of it; of which the usurpers themselves were so sensible that they for the most part endeavoured to vamp up some feeble show of a title by descent, to amuse the people, while they took the possession of the kingdom. And, when possession was once gained, they considered it as the purchase or acquisition of a new estate of inheritance, and transmitted, or endeavoured to transmit it, to their own posterity by a kind of hereditary right of usurpation. See Blackstone's Commentaries, vol. i. 197—217. From the historical view there given it appears that the title to the crown is at present hereditary, though not so absolutely hereditary as formerly; and the common stock, or ancestor, from whom the descent must be derived, is also different. In the time of the Anglo-Saxons the common stock was king Egbert; then William I. introduced a new

race of Normans. In the person of Henry II. the Saxon and Norman blood were united. In Henry VII. were united the blood of the jarring houses of York and Lancaster, whose dissensions had occasioned the shedding of so much royal blood. In Henry's veins too flowed the blood of the British king Arthur, the progenitor of the house of Tudor. By the marriage of Henry VII.'s daughter, Margaret, with king James IV. of Scotland, the royal blood of both kingdoms was united in James V., whose son James VI. united the crowns and the two common stocks; and so continued till the vacancy of the throne in 1688, when William III., Mary II., and Anne succeeded; but the succession was fixed in the heirs of the princess Sophia, in whom the inheritance was vested by the new king and parliament. Formerly, the descent was absolute, and the crown went to the next heir without any restriction; but now, upon the new settlement, the inheritance is continued; being limited to such heirs only of the body of the princess Sophia as are Protestant members of the church of England, and are married to none but Protestants. And in this due medium consists the true constitutional notion of the right of succession to the imperial crown of these kingdoms. The extremes between which it steers are each of them equally destructive of those ends for which societies were formed and are kept up. Where the magistrate, upon every succession, is elected by the people, and may, by the express provision of the laws, be deposed (if not punished) by his subjects, this may sound like the perfection of liberty, and look well enough when delineated on paper; but in practice will be ever productive of tumult, contention, and anarchy. And, on the other hand, divine indefeasible hereditary right, when coupled with the doctrine of unlimited passive obedience, is surely of all constitutions the most thoroughly slavish and dreadful. But, when such an hereditary right as our laws have created and vested in the royal stock, is closely interwoven with those liberties which are equally the inheritance of the subject, this union will form a constitution in theory the most beautiful of any, in practice the most approved, and, we trust, in duration the most permanent. Et esto perpetua! Amen.

In France the succession to the monarchy was formerly limited to heirs male (see *SALIC*), but in Navarre the crown was inherited by the heir of line, whether male or female. Philip IV., king of France, in 1285, espoused Jane queen of Navarre in her own right; and, as king consort of this latter kingdom, added the title of Navarre to that of France. Louis X., son and heir of Philip and Jane, succeeded to both crowns. By Margaret his first wife, who had been crowned queen of Navarre, he left one daughter Joan. His second wife Clementina was pregnant at the time of his decease, and was delivered of a posthumous son, whom most of the French annalists recognise as John I. of France, though he lived only three weeks. On his death the kingdom of France passed to Philip V., and that of Navarre to Joanna the only child and heir of Louis X. and Margaret. From Joanna, in lineal succession, the kingdom of Navarre passed to Jane

d'Albert, mother of Henry IV. of France; and wife of Anthony of Bourbon, who, as king consort, wore the crown of Navarre. On the accession of Henry to the kingdom of France the two monarchies were united, and the four succeeding princes assumed the joint titles.

SUCCINAS, or **SUCCINAT** (from Lat. *succinum*, amber), a salt formed by the combination of the succinic acid with different bases. 'These bases are acids, alkalies, and metallic oxides. But scarcely any of these succinats have yet been examined with attention. 'For the few experiments (adds Dr. Thomson) that have been made, we are indebted to Stockar, Wenzel, Leonhardi, and Bergman.' The doctor then enumerates seven species besides the metallic succinats; viz. 1. Succinat of alumina. This salt, according to Wenzel, crystallises in prisms, and is easily decomposed by heat. 2. Succinat of ammonia forms needle-shaped crystals. It has a sharp bitter and cooling taste; when exposed to heat it sublimes without decomposition. 3. Succinat of barytes. This salt, according to Bergman, is difficultly soluble in water. 4. Succinat of lime. This salt forms oblong, pointed, non-deliquestent salts, which are difficultly soluble even in boiling water. It is not altered by exposure to the air. It is decomposed by muriat of ammonia, and by the fixed alkaline carbonats. 5. Succinat of magnesia has the form of a white, glutinous, frothy mass; which, when dried by the fire, attracts moisture from the air, and deliquesces. 6. Succinat of potass. This salt, according to Leonhardi and Stockar, crystallises in three-sided prisms. It has a bitter saline taste, is very soluble in water, and deliquesces when exposed to the air. When exposed to heat it decrepitates and melts, and in a strong heat is decomposed. 7. Succinat of silver. See *SILVER*. 8. Succinat of soda. When pure succinic acid is saturated with soda, the solution by spontaneous evaporation yields beautiful transparent crystals of succinat of soda; some of which are four-sided prisms with dihedral summits; others six-sided prisms terminated by an oblique face. This salt has a bitter taste, is less soluble in water than common salt, and does not deliquesce when exposed to the air. It is decomposed completely when exposed to a sufficient heat in close vessels. See *SUCCINIC ACID*.

SUCCINATED, impregnated with amber, or the succinic acid.

SUCCINCT, *adj.* French *succinct*; Lat. *succinctus*. Literally tucked or girded up; having the clothes drawn up to disengage the legs: hence short; concise.

A strict and *succinct* style is that where you can take nothing away without loss, and that loss manifest. *Ben Jonson.*

Let all your precepts be *succinct* and clear,
That ready wits may comprehend them soon.

Roscommon.

I'll recant, when France can shew me wit
As strong as ours, and as *succinctly* writ. *Id.*
I shall present you very *succinctly* with a few reflections that most readily occur. *Boyle.*

His vest *succinct* then girding round his waist,
For'th rushed the swain. *Pope.*

SUCCINIC (from Lat. *succinum*, amber), of or belonging to amber; containing the vir-

tues or essence of amber; of the nature of amber.

SUCCINIC ACID, or the acid of amber, one of the recently discovered acids extracted from amber. See **AMBER** and **CHEMISTRY**, Index. When amber (says Dr. Thomson, vol. ii. p. 134) is distilled, a volatile salt is obtained, which is mentioned by Agricola under the name of salt of amber; but its nature was long unknown. Boyle was the first who discovered that it was an acid. It is obtained by the following process:—Fill a retort half way with powdered amber, and cover the powder with dry sand; lute on a receiver and distil in a sand bath, without employing too much heat. See **CHEMISTRY**. Dr. Thomson adds, 'It may be made tolerably pure by dissolving it in hot water, and putting upon the filter a little cotton moistened with oil of amber; this substance retains most of the oil, and allows the solution to pass clear. This acid is then to be crystallised by a gentle evaporation, to be repeated till the acid be sufficiently pure.' Guyton Morveau has discovered that it may be made quite pure by distilling off it a sufficient quantity of nitric acid, taking care not to employ a heat strong enough to sublime the succinic acid. The crystals are transparent, white, shining, and of a foliate, triangular, prismatic form; they have an acid taste, but are not corrosive: they redden tincture of turnsole, but have little effect on that of violets. They sublime when exposed to a considerable heat, but not at the heat of a water bath. In a sand bath they melt, and then sublime and condense in the upper part of the vessel; but the coal which remains shows that they are partly decomposed. One part of this acid dissolves in ninety-nine parts of water, at the temperature of 50°, according to Spielman in twenty-four parts at 52°; and in two parts of water at 212°, according to Stockar de Neuforn; but the greatest part crystallises as the water cools. According to Rox, however, it still retains more of the acid than cold water is capable of dissolving; 240 grains of boiling alcohol dissolve 177 of this acid; but crystals again shoot as the solution cools. The compounds which it forms with acids, alkalies, and metallic oxides, are named succinats. When the succinat of soda is distilled in a retort the succinic acid is completely decomposed. There passes over into the receiver an acid liquor, which is the acetous much diluted and a quantity of brown oil. At the same time carbonic acid gas, and carbonated hydrogen gas, are disengaged, and there remains in the retort soda and charcoal. Hence it follows that this acid is decomposed by heat, and is composed of oxygen, hydrogen, and carbon. Its affinities, Morveau says, are barytes, lime, potass, soda, ammonia, magnesia, alumina, metallic oxides.

SUCCINUM, amber, in mineralogy, a species of bitumen classed under the inflammable substances. As a full account of this mineral was given under **AMBER**, nothing remains but to mention a few things which recent experiments enable us to add. According to Dr. Kirwan 100 grains of amber afford about seventy-two of petroleum, forty-five of succinic acid, and a residue of fixed matter and water. Mr. Scheele says that

when distilled it yields an aqueous acid resembling vinegar in its qualities. This would induce us to believe it to be of vegetable origin. But its origin is a point not yet ascertained. Its specific gravity is from 1.065 to 1.100, and it melts at 550° of Fahrenheit. Wallerius affirms that mirrors, prisms, &c., may be made of amber.

SUCCORY, *n. s.* Lat. *cichoreum*. A plant.

A garden sallad

Of endive, radishes, and succory.

Dryden.

The medicaments to diminish the milk are lettuce, purslane, endive, and succory.

Wiseman of Tumours.

SUCCORY, in botany. See **CICORIUM**.

SUCCORY, gum. See **CHONDRILLA**.

SUCCORY, wart. See **LAPSANA**.

SUCCOTH BENOTH, a goddess of the Chaldeans; supposed to be the same with Mylitta or the Assyrian Venus; in honor of whom the young women were obliged to prostitute themselves once in their lives in her temple; where each was called on in her turn by a man throwing a piece of money in her lap. The worship of this obscene goddess was introduced into Samaria, along with the corrupted worship of the true God, by the Babylonian emigrants settled there by Shalmanezar, 2 Kings xvii. 30. As Succoth signifies tents, perhaps the rites of Succoth Benoth were celebrated in tent-beds.

SUCCOUR, *v. a. & n. s.* } French *secourir*;

SUCCOURLESS, *adj.* } *la. succurro*. To

help; assist in difficulty or distress; relieve: the noun substantive and adjective corresponding.

She hath been a succourer of many.

Rom. xvii. 2.

Fear nothing else but a betraying of succour which reason offereth.

Wisdom xvii. 12.

As that famous queen

Of Amazons, whom Pyrrhus did destroy,

Did shew herself in great triumphant joy,

To succour the weak state of sad afflicted Troy.

Spenser.

Here's a young maid with travail oppress'd,

And faints for succour.

Shakspeare.

Our watchful general hath discerned from far

The mighty succour which made glad the foe.

Dryden.

A grateful beast will stand upon record, against those that in their prosperity forget their friends, that to their loss and hazard stood by and succoured them in their adversity.

L'Estrange.

Succourless and sad,

She with extended arms his aid implores.

Thomson.

SUCCUBUS, a term used by some writers for a demon who assumes the shape of a woman, and as such lies with a man; in which sense it stands opposed to incubus, which was a demon in form of a man that lies with a woman. But the truth is that succubus is only a species of the incubus, or the night-mare. See **MEDICINE**.

SUCCULENCY, *n. s.* } *Fr. succulent*; *Lat.*

SUCCULENCY, } *succulentus*. Juici-

SUCCULENT, *adj.* } ness; juicy; moist.

These plants have a strong, dense, and succulent moisture, which is not apt to exhale.

Bacon.

Divine Providence has spread her table every where, *...* with a juiceless green carpet, but with succulent herbage and nourishing grass, upon which most beasts feed.

More.

On our account has Jove,

Indulgent, to all lands some succulent plant

Allotted. that poor helpless man might slack
His present thirst. *Philips.*

SUCCULENT PLANTS, among botanists, such
whose leaves are thick and full of juice.

SUCCULENTÆ, in botany, an order of
plants in the natural method. See BOTANY,
Index.

SUCCUMB', *v. n.* Lat. *succumbo*; Fr. *succomber*. To yield; to sink under any difficulty.

To their will we must succumb,
Quocunque trahunt, 'tis our doom. *Hudibras.*

SUCCUSSATION, *n. s.* Lat. *succusso*. A
trot.

They rode, but authors do not say
Whether tulation or succussation. *Butler.*

They move two legs of one side together, which is
tulation or ambling; or lift one foot before, and
the cross foot behind, which is succussation or trotting.
Broune's Vulgar Errors.

When any of that risible species were brought to
the doctor, and when he considered the spasms of the
diaphragm, and all the muscles of respiration, with
the tremulous succussion of the whole human body,
he gave such patients over. *Martin Scriblerus.*

SUCH, *pronoun.* Sax. *ƿilc*; Goth. *sulleiks*;
Belg. *sulk*; Swed. *salik*. So-like; of that kind;
of the like kind; taking as before the thing to
which it relates: the same that; a particular
person or thing, as in the phrase, 'such and
such.'

Can we find such a one as this, in whom the spirit
of God is? *Genesis xli. 33.*

I have appointed my servants to such and such
place. *1 Samuel.*

You will not make this a general rule to debar
such from preaching of the gospel, as have through in-
firmity fallen. *Whitgift.*

If you repay me not on such a day,
In such a place, such sum or sums as are
Expressed in the condition, let the forfeit
Be an equal pound of your flesh.

Shakspeare. Merchant of Venice.
I saw him yesterday

With such and such. *Id. Hamlet.*

Scarce this word death from sorrow did proceed,
When in rushed one, and tells him such a knight
Is now arrived. *Daniel's Civil War.*

That which doth constitute any thing in its being,
and distinguish it from all other things, is called the
form or essence of such a thing. *Wilkins.*

That thou art happy, owe to God;
That thou continuest such owe to thyself. *Milton.*

Such precepts as tend to make men good, singly
considered, may be distributed into such as enjoin
piety towards God, or such as require the good go-
vernment of ourselves. *Tillotson.*

Such another idol was Manah, worshipped be-
tween Mecca and Medina, which was called a rock
or stone. *Stillingfleet.*

Such are the cold Riphean race, and such
The savage Scythian. *Dryden's Virgil.*

The same sovereign authority may enact a law,
commanding such or such an action to-day, and a
quite contrary law forbidding the same to-morrow.

South.

To assert that God looked upon Adam's fall as a
sin, and punished it as such, when, without any an-
tecedent sin, he withdrew that actual grace upon
which it was impossible for him not to fall, highly
reproaches the essential equity of the Divine Nature.
Id.

You love a verse, take such as I can send. *Pope.*

SUCK, *v. a., v. n., & n. s.* } Sax. *ƿucan*; Fr.
SUCK'ER, *n. s.* } *sucer*; Ital. *suc-*
SUCK'ET, } *tiore*; Lat. *sugo,*
SUCK'ING-BOTTLE, } *suctum*. To draw
SUCK'LE, *v. a.* } by making a rare-
SUCK'LING, *n. s.* } faction of the air;
SUCK'ION, } draw in with the

mouth; empty by sucking; draw or drain: as a
verb neuter to draw by rarefaction; draw the
breast; imbibe; the act of sucking; milk given
by females: a sucker is a draining instrument;
the embolus of a pump; a young twig, 'perhaps,'
says Johnson, 'from Lat. *surculus*.' Sucker is a
sweet-meat: sucking-bottle, a bottle to aid child-
ren in sucking, or as a substitute for the breast:
to suckle, to nurse at the breast: suckling, the
creature nursed: suction is the act of sucking.

A nursing father beareth with the sucking child.

Numb. xi.

The cup of astonishment thou shalt drink, and
suck it out. *Ezekiel xxiii. 34.*

Desire, the more he sucked, more sought the breast,
Like dropsy folk still drink to be a-thirst. *Sidney.*

They draw with their suck the disposition of nurses.

Spenser.

Thy valiantness was mine, thou sucked'st it from
me;

But own thy pride thyself. *Shakspeare. Coriolanus.*

The breast of Hecuba,

When she did suckle Hector, looked not lovelier.

Shakspeare.

I can suck melancholy out of a song, as a weasel
sucks eggs. *Id.*

I would

Pluck the young sucking cubs from the she-bear,
To win thee, lady. *Id. Merchant of Venice.*

The cutting away of suckers at the root and body
doth make trees grow high.

Bacon's Natural History.

The crown had sucked too hard, and now, being
full, was like to draw less. *Bacon's Henry VIII.*

Pumping hath tired our men;

Seas into seas thrown, we suck in again. *Donne.*

Nature's confectioner, the bee,
Whose suckets are moist alchemy;

The still of his refining mold
Minting the garden into gold. *Cleaveland.*

The ascent of waters is by suckers, or forcers, or
something equivalent thereunto. *Wilkins's Dædalus.*

Oil must be poured into the cylinder, that the
sucker may slip up and down in it more smoothly.

Boyle.

Though the valve were not above an inch and a
half in diameter, yet the weight kept up by suction,
or supported by the air, and what was cast out of it
weighed ten pounds. *Id.*

We'll hand in hand to the dark mansions go,

Where sucking in each other's latest breath,
We may transfuse our souls. *Dryden.*

Bees on tops of lilies feed,
And creep within their bells to suck the balmy seed.

Id.

Those first unpolished matrons
Gave suck to infants of gigantic mold. *Id.*

I provide a suckling,

That ne'er had nourishment but from the teat. *Id.*

She nurses me up and suckles me. *L'Estrange.*

A fox lay with whole swarms of flies sucking and
galling of him. *Id.*

He that will say children join these general ab-
stract speculations with their sucking-bottles, has more
zeal for his opinion, but less sincerity. *Locke.*

Such as are nourished with milk find the paps and

suck at them ; whereas none of those that are not designed for that nourishment ever offer to suck.

Ray on the Creation..

Out of this old root a *sucker* may spring, that with a little shelter and good seasons, may prove a mighty tree.

Ray.

Continual repairs, the least defects in *sucking* pumps are constantly requiring.

Mortimer's Husbandry.

Marines aye ply the pump,

So they, but cheerful, unfatigued, still move

The draining *sucker*.

Philips.

One of the round leathers wherewith boys play, called *suckers*, not above an inch and half diameter, being well soaked in water, will stick and pluck a stone of twelve pounds up from the ground.

Crew's Museum.

The Roman soldiers bare on their helmets the first history of Romulus, who was begot by the god of war, and *sucked* by a wolf.

Addison on Italy.

Young animals participate of the nature of their tender aliment, as *sucklings* of milk.

Arbutnot on Aliments.

Transfixed as o'er Castalia's streams he hung,
He *sucked* new poisons with his triple tongue,

Pope's Statius.

SUCKLING (Sir John), an English poet and dramatic writer, was the son of Sir John Suckling, comptroller of the household to king Charles I., and born at Witham in Essex, in 1613. He discovered an uncommon propensity to the acquiring of languages, insomuch that he is reported to have spoken Latin at five years of age, and to have written it at nine. When he was grown up he travelled ; but seems to have affected nothing more than the character of a courtier and a fine gentleman ; which he so far attained that he was allowed to have the peculiar happiness of making every thing he did become him. In his travels he made a campaign under the great Gustavus Adolphus : and his loyalty, if not his valor, appeared in the beginning of our civil wars ; for, after his return to England, he raised a troop of horse for the king's service entirely at his own charge ; and mounted them so completely and richly that they are said to have cost him £12,000. But his troop, with Sir John at its head, behaved so ill in the engagement with the Scots, upon the English borders, in 1639, as to occasion the famous lampoon composed by Sir John Mennis :—

' Sir John he got him an ambling nag, &c.'

This ballad, which was set to a brisk tune, was much sung by the parliamentarians. This disastrous expedition, and the ridicule that attended it, was supposed to have hastened his death ; being seized by a fever, of which he died, at twenty-eight years of age. He was a sprightly wit, and an easy versifier, but no great poet. His works, consisting of a few poems, letters, and plays, have nevertheless gone through several editions.

SUCRO, a river of Hispania Tarraconensis, famous for a battle fought on its bank between Sertorius and Pompey the Great, in which the latter was defeated. It is now called Xucar.

SUCTION, in physiology, the act of drawing into the mouth fluids and other substances by means of the pressure of the external air. When an infant is imbibing its food from the breast of the mother its lips are applied closely to the

nipple, so that no air can enter ; by enlarging the chest, the atmospheric pressure is removed from the surface of the nipple, while it still continues on the external surface of the breast ; and thus forces the contents of the lactiferous tubes into the mouth. If the lips are immersed in any fluid, and the chest expanded, the pressure of the external atmosphere will force it into the mouth. The act of suction, indeed, depending on this atmospheric pressure, is in all cases essentially the same. See **LUNGS**. Air is sucked through a pipe in the same manner as with the naked mouth ; it being here the same as if the mouth were extended through the length of the pipe. If a man apply his mouth to one end of an open tube, the other end of which is placed in water, the operation of sucking is performed in the following manner. By enlarging his chest, he rarefies the air, and of course diminishes its pressure on the liquor, which is immediately under the tube ; in consequence of which the pressure of the atmosphere on the surface of the surrounding liquor forces the liquor to ascend into the tube.

The suction of heavier liquors is performed after the same manner, e. gr. in lying prone to drink out of a spring, &c., the lips are applied close to the surface of the water, so as to prevent any passage of the air between them ; then the cavity of the abdomen, &c., being distended as before, the pressure of the air incumbent on the surface of the water, without the circumference of the mouth, prevailing over that upon the water within the same, the fluid is raised from the same principle as water in a pump. In sucking a heavy liquor, as water, through a pipe, the longer the pipe is, the greater difficulty is found in the suction ; and the bigness and diameter of the pipe make a farther alteration therein. The reason of this arises from that great principle in hydrostatics, that fluids press in the compound ratio of the bases, and perpendicular altitudes.

From what we have said, it evidently enough appears that what we call suction is not performed by any active faculty in the mouth, lungs, &c. ; but by the mere impulse and pressure of the atmosphere. A very curious and intelligent person distinguishes two different sorts of suction, performed after two quite different manners ; a distinction which, however hitherto overlooked by authors, seems absolutely necessary.

Suction then, according to him, is performed either, 1st, by the dilatation of the thorax ; or, 2dly, by that of the cavity of the mouth. In the former case the lungs are kept continually distended ; for, if the breath be let go ever so little, the liquor in the tube will begin to subside. On the contrary, when suction is performed by enlarging the cavity of the mouth, we may suck with our utmost force, and yet breathe freely through the nostrils at the same time. This is the true proper suction : the other ought rather to be called supping than sucking through a tube.

Note, the cavity of the mouth is enlarged by being a little opened, while the lips are close shut, the tongue being at the same time contracted, and drawn backwards towards the throat.

In the operation of sucking, after the manner of children, the rarefaction is produced in the

fore part of the mouth; i. e. the tongue is applied so as to fill up the space between the lips and the nipple, or pipe which conveys the milk or other liquor; then the tongue is drawn backwards, whilst the lips are laterally pressed against it, by which means a small vacuum is formed before it, and the liquor is forced into that vacuum by the pressure of the atmosphere upon its external surface, or upon the surface of the bag which contains it. It is for the same reason that snails remain attached to solids, that limpets adhere very firmly to rocks, that the sea polypus holds with great force whatever it fastens its claws to, and that some insects suspend themselves to solids; for, though not performed with the mouth, the principle of the operation is exactly the same, viz. a soft membrane is applied to the solid, then the middle part of that surface is withdrawn a little way, so as to form a vacuum, or at least a rarefaction of the air between the centre of the soft membrane and the solid, in consequence of which the parts of the membrane which surround that spot are, by the gravity of the atmosphere, pressed against the solid, and the latter is pressed against the former; hence the adhesion takes place.

Leather suckers, which act precisely upon the same principle, are not unfrequently seen in the hands of boys about the streets of London. A circular piece of thick leather, about two inches in diameter, has a string fastened to its centre. The leather, being previously well soaked in water, is applied flat and close to the smooth surface of a stone. The interposition of a little water promotes the adhesion. Then the boy pulls up the string, and the stone, if not too heavy, comes up adhering to the leather. The claws of the polypus are furnished with a great many suckers of the like nature. The limpet forms one sucker of its whole body, and the same thing, with little variation, is done by various other animals, especially of the insect tribe. The action of the glass cup, which is made to adhere to the flesh, for the purpose of bleeding, depends upon the same principle; excepting that the air within the glass cup is rarefied by means of heat, or by means of a small exhausting engine. It is hardly needful to add that the limpet could not adhere to the rock, nor could the leather sucker act, or, in short, that none of those sucking operations could take place, in vacuo.

SUCZAVA, an ancient town in the Bukovine, Austrian Galatia, at the confluence of the Suczava and Sereth. It is surrounded with a wall and ditch, and contains about 4000 inhabitants, but is only a shadow of what it once was, having been the residence of the princes of Moldavia, the ruins of whose palace, with those of seventeen large churches, bear testimony to its former grandeur. At present it contains hardly any establishment worth notice, except a manufactory of Russian leather, and a school for training teachers for the adjacent country. Seventy miles west of Jassy, and ninety-seven S. S. E. of Lemberg.

SUDBURY, a borough and market-town, consisting of three parishes, in Babergh hundred, Suffolk, situated on the river Stour, fourteen miles S.S.E. of Bury-St.-Edmund's, and fifty-four north-

east of London. The streets are tolerably well built, and there are three handsome churches; viz. St. Gregory's, St. Peter's, and All-Saints'; over the river is a good stone bridge. The traffic of the town has much increased since the Stour has been made navigable for barges to Manningtree. It is said to have been one of the first towns in which the woollen manufactory was introduced, but that is now gone to decay, and is succeeded by serges and a silk manufactory. It first returned members to parliament in 1559; and now sends two, chosen by those who are free of the borough, the number of voters being about 720. It is governed by a mayor, six aldermen, and twenty-four common councilmen. Market on Saturday. Fairs 12th of March and 10th of July.

SUDD'EN, *adj.* & *n. s.* } Sax. *roden*; Fr. *soudain*. Happening

SUDD'ENLY, *adv.* } without notice; coming without common preparatives: hence hasty; violent: as a noun substantive, surprise; an unexpected occurrence; thus 'on a sudden' is sooner than could have been anticipated: the adverb and noun substantive following correspond.

All in the open hall amazed stood,
At suddenness of that unwary sight,
And wondered at his breathless hasty mood.

Spenser.

He speedily run forward, counting his suddenness his most advantage, that he might overtake the English.

Id.

We have not yet set down this day of triumph;
To-morrow, in my judgment, is too sudden.

Shakpeare.

I grant him

Sudden, malicious, smacking of every sin. *Id.*

Following the flyers at the very heels,
With them he enters, who upon the sudden
Clapt to their gates. *Id. Macbeth.*

If thou canst accuse,
Do it without invention suddenly. *Id. Henry VI.*

If elision of the air made the sound, the touch of the bell or string could not extinguish so suddenly that motion. *Bacon.*

Parents should mark the witty excuses of their children at suddains and surprisals, rather than pamper them. *Wotton.*

SUDERMANTIA, or SODERMANLAND, a province of Middle Sweden, to the west of Stockholm. Its greatest length from east to west is about 100 miles; its breadth from north to south fifty-five: its territorial extent is 3470 square miles. The face of the province is hilly, finely variegated with lakes: the climate, though cold, is not intemperate; and the air is pure and healthy. The inhabitants raise corn in sufficiency for consumption and a small export. The pasturage is good; the forests extensive. In the mountains are mines of lead, copper, iron; and from Tunaberg a large quantity of cobalt ore is sent to England. Population 150,000.

SUDETES, a large mountain chain of Germany, separating the Austrian states from those of Saxony and Prussia. It is distinguished by the names of the Erzgebirge and the Riesengebirge, viz. the Mining and the Giant's Mountains. Besides this great chain it sends off on both sides a number of branches into Bohemia, Moravia, Lusatia, and Silesia.

SUDORIFIC, *adj.* & *n. s.* Fr. *sudorifique*; Lat. *sudor* and *fucio*. Provoking or causing sweat: the noun substantive corresponding.

Physicians may well provoke sweat in bed by bottles, with a decoction of *sudorifick* herbs in hot water.

Bacon.

Exhaling the most liquid parts of the blood by *sudorifick* or watery evaporations, brings it into a morbid state.

Arbutnot.

As to *sudorificks*, consider that the liquid which goes off by sweat is often the most subtle part of the blood.

Id.

SUDOROUS, *adj.* Lat. *sudor*. Consisting of sweat. Not used.

Beside the strigments and *sudorous* adhesions from men's hands, nothing proceedeth from gold in the usual decoction thereof. *Brounè's Vulgar Errors.*

SUE, *v. a.* & *v. n.* Fr. *suiver*; Lat. *sequor*; Gr. ζέω. To prosecute by law; to petition; to entreat; to beg: obtain by law or petition.

If any *sue* thee at the law, and take away thy coat, let him have thy cloak also. *Matt. v. 40.*

Full little knowest thou that hast not tried,

What hell it is in *suing* long to bide. *Spenser.*

If me thou deign to serve and *sue*,

At thy command, lo! all these mountains be. *Id.*

Ambassadors came unto him as far as the mouth of the Euphrates, *suing* unto him for peace. *Knolles.*

We were not born to *sue*, but to command. *Shakspeare.*

For this, this only favor let me *sue*,

Refuse it not: but let my body have

The last retreat of human kind, a grave.

Dryden's Æneid.

'Twill never be too late,

To *sue* for chains, and own a conqueror.

Addison's Cato.

The fair Egyptian

Courted with freedom now the beauteous slave,

Now faltering *sued*, and threatening now did rave.

Blackmore.

By adverse destiny constrained to *sue*,

For counsel and redress, he *sues* to you.

Pope's Odyssey.

SUE (John Joseph), F. R. S., an eminent French surgeon, who was surgeon in chief of the hospitals at Paris. He wrote several learned works on surgery and medicine; and was admitted F. R. S. of London. He died in 1792.

SVEABORG, a sea port and fortress on the Gulf of Finland, three miles and a half south of Helsingfors. The harbour, capable of containing seventy men of war, is defended by batteries which sweep the channel forming its only entrance. Here are several small islands, of which the principal, called Wargoe, contains the arsenal, docks, basins, and magazines for fitting out or repairing men of war. The fortifications are likely, when completed, to stand a comparison with Gibraltar, and the garrison often amounts to 3500 men. The works were begun in 1748, and continued by the Swedish government, with more or less activity, from that date to 1808, when the place falling into the hands of the Russians, they have been farther continued. The walls are chiefly of granite, covered with earth from six to ten feet in thickness, and in some places forty in height. In 1790 Gustavus III. of Sweden defeated the Russians in a naval engagement near this place. Population 3500.

SUECA, a town in the province of Valencia,

Spain, not far from the mouth of the Xucar, joined here by a small stream flowing from the lake of Albufera. It stands on the great road along the coast, contains 4800 inhabitants, and belonged formerly to the grand master of the knights of Montesa. Twenty-one miles south of Valencia.

SUESSI, **SUESSIONES**, **SUESSONES**, a branch of the Remi, a people of Gallia Belgica (Pliny) called sometimes Suesones, in the lower age Suesi; situated between the Remi to the east, the Nervii to the north, the Veromandoui to the west, and the Meldæ to the south, in the tract now called Soissonois.

SUESSONES, **SUESSIONES**, or **SUESSONET**, the name of their city in the lower age; thought to have been formerly called Noviodunum (Cæsar), now called Soissons. See SAXONY, SOISSONNOIS, and SOISSONS.

SU'ET, *n. s.* From old Fr. *suet*, according to **SU'ETY**, *adj.* } to Skinner. A hard fat, particularly that about the kidneys: of the nature of or abounding in *suet*.

The steatoma being *suet*, yields not to escharotics.

Wiseman.

If the matter forming a wen resembles fat, or a *suet* substance, it is called steatoma.

Sharp's Surgery.

SUET, sebum, a fat found in deer, sheep, oxen, hogs, &c., which, melted down and clarified, makes what we call tallow, used in the making of candles. The word is formed from the Latin *suedum*, *sebum*, or *sevum*, which signify the same; and these a *sue*, *sow*, by reason of the fatness of that beast.

Of all real animal fats mutton-suet is the most consistent; it has some degree of brittleness, and requires a temperature of 127° Fahrenheit to melt it. In other respects it agrees with animal fats in general. Like these it is emollient: it is sometimes boiled in milk in the proportion of ʒij of the *suet* to ʒj of milk, and a cupful of the mixture is given occasionally in chronic diarrhœa when there is much acrimony of the contents of the bowels; but its principal use is to give consistence to ointments and plasters. The *sebum præparatum*, or prepared *suet* of the London pharmacy, is obtained by cutting the *suet* in pieces, then melting it by a gentle heat, and pressing it through linen. Another kind of fat which we shall mention is the *xungia porcina* of the Edinburgh pharmacy, the *adeps suillus* of Dublin, the *adeps* of London, or the hog's lard. The lard is chiefly obtained from the flank of the animal. It is freed from the membranes and vessels by being cut in small pieces, then well washed in water till the water comes off colorless, and afterwards melted with a very gentle heat in a shallow vessel, kept on the fire till the water is wholly evaporated. While still liquid it is poured into bladders, in which it concretes, and in this state it is brought to market.

This fat is inodorous, tasteless, and white; soft, and nearly semifluid. Exposed to a heat of 97° it melts, and concretes again when cooled. It is insoluble in water, alcohol, and ether: but is dissolved by the strong acids, being at the same time decomposed; and, like the fixed oils, it combines with the alkalies and forms soap. It

is oxidised if when melted a little nitric acid be stirred into it; and assumes a greater degree of firmness, with a yellow color. By destructive distillation it affords results very similar to those obtained from the analysis of fixed oil; and appears to be a compound of oxygen, hydrogen, and carbon, in unknown proportions. When lard is long exposed to a warm air it becomes yellow, emits a fœtid odor, and, owing to oxygen being attracted from the atmosphere, the sebacic acid is formed. This state of rancidity may in some degree be removed by washing it with very pure soft water; which during the operation becomes acid, and reddens litmus paper. Lard is emollient, and on account of its softness and unctuousity is preferable to fat as a friction, but seldom used for this purpose; and is chiefly employed in the formation of ointments. Its officinal preparation is the *adeps præparata*, or prepared lard. That of the London pharmacopœia is obtained by cutting the fat into small fragments, then melting it by a gentle heat, and pressing it through linen. The *adeps suillus præparatus*, or prepared hog's lard of the Dublin pharmacopœia, is had by cutting fresh lard into small pieces, then melting it by a moderate heat, and straining by pressing it through a linen cloth. Lard prepared by the dealers, and preserved with salt, is to be melted with twice its weight of boiling water, and well stirring the mixture: it is then allowed to cool, when the lard may be separated. The above-mentioned processes are intended for purifying suet and lard; but in order to obtain them very pure they should be washed in water till the water comes off colorless, before they be melted. During the melting the remaining water is evaporated; and that this is the case may be ascertained by throwing a little of the melted fat into the fire, when it will crackle if any water remain. The heat must not be raised above 97°, the melting point of fat; because otherwise the fat is decomposed, rendered acrid, and assumes a yellow color. This purification is seldom attempted by the apothecary, as both kinds of fat may be procured very well purified from the dealers. To keep lard clean, and preserve it from the action of the air, it is, as we have already said, run into bladders in its liquid state.—Thomson's Disp.

SUETONIUS TRANQUILLUS (Caius), a famous Latin historian, was born at Rome, and became secretary to the emperor Adrian, about A. D. 118; but that post was taken from him three years after, for not showing the empress Sabina all the respect she deserved. During his disgrace he composed many works, which are lost. Those extant are his History of the Twelve Cæsars, and a part of his Treatise of the Illustrious Grammarians and Rhetoricians. Pliny the Younger was his intimate friend, and persuaded him to publish his books. His History of the Twelve Cæsars has been much commended by many of the literati. He represents, in a series of curious particulars, without digressions or reflections, the actions of the emperors, exposing their vices in all their deformity; yet mentions their good qualities; but the horrid dissoluteness and obscene actions he

relates of Tiberius, Caligula, Nero, &c., have made some say that he wrote the lives of the emperors with the same licentiousness with which they lived. The edition of this history by Grævius at Utrecht, in 1672, with the excellent Commentaries of Torrentius and Casaubon, and the notes of some other learned critics, is much esteemed.

SUETRI, an ancient nation of Gaul, who inhabited near the Alps.

SUEVI. See **ALEMANNI**.

SUEVI, the Catti or Chatti of Cæsar, an ancient nation of Germany, who lived on the Rhine; considerably distant from the proper Suevi or Alemanni. See **SAXONS**.

SUEVI, a common name of the people situated between the Elbe and the Vistula (Tacitus), distinguished otherwise by particular names; as in Ptolemy, Suevi Angeli, Suevi Senones.

SUEUR (Eustace le), an eminent French painter, born at Paris in 1617. He studied under Simon Vouet, but soon greatly excelled him. Although he was never out of France, he attained the highest degree of perfection. His works, which are chiefly at Paris, exhibit a grand style, formed upon antiquity, and after the best masters. His master-piece is St. Bruno, formerly in the convent of Carthusians, probably now in the National Museum. He died in 1655, aged only thirty-eight.

SUEVUS, in ancient geography, a river of Germany, thought to be the same with the Viadrus or Oder, running by three mouths into the Baltic, the middlemost of which is called Swine or Swene.

SUEZ, a city of Egypt, remarkable for its situation at the head of the Red Sea, on the borders of Arabia. The existing city appears to have been of modern origin. According to D'Anville it occupies the site of the ancient Arsinoe. Volney thinks that place was situated farther north, towards the bottom of the gulf. The celebrated Arabian city called Kolzum, which among that people gave its name to the Red Sea, was also farther to the north. Its ruins may still be traced. Suez, about the beginning of the sixteenth century, became a flourishing mart, being at once the emporium of the trade with India, and the rendezvous of the numberless pilgrims who went from every part of the Turkish empire to Mecca. When Niebuhr was there, Suez appeared to him as populous as Cairo. Since that time it has greatly declined, in consequence of the diminution both of the general trade of the Red Sea, as well as of the concourse to Mecca. It sustained, also, irreparable injury from the devastations of the French. Great part of the trade being carried on by the Beys, each of whom had a factor stationed here, the French, in revenge for the spirited resistance made by that race, demolished a great part of the town.

Suez is so situated that vessels cannot approach nearer than two miles and a half. From this point the water is divided into three channels, which unite before reaching the town. The surrounding country is a complete desert, composed of a bed of rock, slightly covered with sand. All provisions and necessaries of life are brought

from Cairo. Its very bad water also is brought from the distance of about two leagues, at the opposite side of an arm of the gulf. The town contains about 500 stone houses, of which more than half were destroyed by the French. It has no walls; but the houses are built so close together that it can be entered from the land side only at one point, defended by three canon; eight are placed on the side towards the sea. Mr. Turner conceives Suez to be indisputably the most miserable place in the Levant, and that only the settled passion for money, which characterises the Levantines, could induce any man to make it his residence. Its trade lies under many disadvantages, particularly from the difficult navigation of this part of the Red Sea, where vessels can only pass through a narrow channel, amid rocks often sunk beneath the surface. Danger also arises from the north winds, which blow with great violence for nine months. Cosseir, which is less liable to these disadvantages, is now, notwithstanding the inconvenience of a longer and more difficult land journey, often preferred for the trade to Egypt. Suez, however, still carries on much of the communication of Syria, Arabia, and India, with Cairo. Coffee is the staple import.

SUFFER, *v. a. & v. n.* } Fr. *souffrir*; Lat. }
 SUFFERABLE, *adj.* } *suffero*. To endure; }
 SUFFERABLY, *adv.* } undergo; support; }
 SUFFERANCE, *n. s.* } pass through; be af- }
 SUFFERER, } fected by; allow; }
 SUFFERING. } permit: to undergo }
 pain, inconvenience, or penalty; he injured: sufferable is tolerable; such as may be endured: the adverb corresponding: sufferance, inconvenience; pain; tolerance; permission; moderation: a sufferer, one who endures suffering; one who permits or allows (unusual): suffering is pain or inconvenience suffered.

Rebuke thy neighbour, and not suffer sin upon him. *Leviticus.*

A man of great wrath shall suffer punishment. *Prov. xix.*

A woman suffered many things of physicians, and spent all she had. *Mark v. 26.*

He thought t' have slain her in his fierce despite; But hasty heat tempering with sufferance wise, He staid his hand. *Spenser.*

In process of time, somewhiles by sufferance, and somewhiles by special leave and favor, they erected to themselves oratories not in any sumptuous or stately manner. *Hooker.*

He wondered that your lordship Would suffer him to spend his youth at home. *Shakspeare.*

Oft have I seen a hot o'erweening cur Run back and bite, because he was withheld: Who being suffered, with the bear's fell paw Hath clapt his tail betwixt his legs and cried. *Id.*

Some villains of my court Are in consent and sufferance in this. *Id.*

He must not only die, But thy unkindness shall the death draw out To lingring sufferance. *Id. Measure for Measure.*

Thy rages be Now no more sufferable. *Chapman.*

He hath given excellent sufferance and vigorousness to the sufferers, arming them with strange courage. *Taylor.*

It is *sufferable* in any to use what liberty they list in their own writing, but the contracting and extending the lines and sense of others would appear a thankless office. *Watton.*

This evil on the Philistines has fallen, The sufferers then will scarce molest us here: From other hands we need not much to fear. *Milton.*

To suffer, as to do, Our strength is equal, nor the law unjust That so ordains. *Id.*

Obedience imposed, On penalty of death, and suffering death. *Id.*

Both gloried to have escaped the Stygian flood, As gods, and by their own recovered strength; Not by the sufferance of supernal power. *Id. Paradise Lost.*

The air now must suffer change. And, should I touch it nearly, bear it With all the sufferance of a tender friend. *Milton.*

Nor was his sufferance of other kinds less exemplary than that he evidenced in the reception of calamity. *Otway's Orphan.*

Publick business suffers by private infirmities, and kingdoms fall into weaknesses by the diseases or decays of those that manage them. *Fell.*

He thus Was forced to suffer for himself and us! Heir to his father's sorrows with his crown. *Temple.*

Heir to his father's sorrows with his crown. *Dryden.*

SUFFERANCE, in law. Tenant at sufferance is he who holdeth over his term at first lawfully granted.—Terms de Ley. A person is tenant at sufferance that continues after his estate is ended, and wrongfully holdeth against another, &c.—1 Inst. 57. An estate at sufferance is where one comes into possession of land by lawful title, but keeps it afterwards without any title at all. As if a man takes a lease for a year, and, after the year is expired, continues to hold the premises without any fresh leave from the owner of the estate. Or, if a man maketh a lease at will, and dies, the estate at will is thereby determined; but, if the tenant continueth possession, he is tenant at sufferance.—Co. Litt. 57. But a lease at will being now considered as a lease from year to year, which cannot be vacated without half a year's notice to quit, the tenant cannot be ejected at the death of the lessor without half a year's notice from his heir.—2 Term Rep. 159. And it is also necessary, in case of the death of the tenant, to give that notice to his personal representative.—3 Wils. 25. No man can be tenant at sufferance against the king, to whom no laches or neglect, in not entering and ousting the tenant, is ever imputed by law; and his tenant, so holding over, is considered as an absolute intruder.—1 Inst. 57. But, in the case of a subject, this estate may be destroyed whenever the true owner shall make an actual entry on the lands and oust the tenant; for, before entry, he cannot maintain an action of trespass against the tenant by sufferance as he might against a stranger; and the reason is, because the tenant being once in by a lawful title, the law (which presumes no wrong in any man) will suppose him to continue upon a title equally lawful, unless the owner of the land, by some public and avowed act, such an entry is, will de-

clare his continuance to be tortious, or, in common language, wrongful.—1 Inst. 57 : 2 Comm. c. 9, p. 150.

SUFFETES, magistrates of Carthage.

SUFFETIUS. See METIUS and ROME.

SUFFETULA, an ancient town of Africa, in the dominions of Carthage, probably so called from suffetes, the title of the magistrates of that city. It is now called Spaitla, in the kingdom of Tunis, and has many elegant remains of antiquity. There are three temples in a great measure entire; one of them of the Composite order, the other two Corinthian. The town lies in the most beautiful spot in Barbary, surrounded by great numbers of juniper trees; and watered by a pleasant stream, which sinks under the earth at that place, without appearing any more. See SPAITLA.

SUFFICE, *v. n. & v. a.* } Fr. *suffire*; Lat. *sufficio*. To be
SUFFICIENT, *adj.* } enough; be suffi-
SUFFICIENTLY, *adv.* } cient, or efficient,
to an end or purpose : as a verb active to afford ; supply ; satisfy : sufficiency is, competency ; qualification for a purpose ; enough : sufficient, equal to an end or purpose ; qualified : the adverb corresponding.

Parched corn she did eat, and was sufficed, and left. *Ruth.*

Israel, let it suffice you of all your abominations. *Ezek.*

Sufficient unto the day is the evil thereof.

Matthew vi. 34.

If religion did possess sincerely and sufficiently the hearts of all men, there would need be no other restraint from evil. *Hooker.*

If thou ask me why, *sufficeth*, my reasons are good. *Shakespeare.*

In saying he is a good man, understand me, that he is sufficient. *Id. Merchant of Venice.*

I am not so confident of my own sufficiency, as not willingly to admit the counsel of others. *King Charles.*

Seem I to thee sufficiently possessed
Of happiness? *Milton.*

To recount almighty works,
What words or tongue of seraph can suffice,
Or heart of man suffice to comprehend? *Id.*

Let it suffice thee that thou knowest us happy. *Id.*

Heaven yet retains
Number sufficient to possess her realms. *Id.*

His sufficiency is such that he bestows and possesses, his plenty being unexhausted. *Boyle.*

Man is not sufficient of himself to his own happiness. *Tillotson.*

Sufficiency is a compound of vanity and ignorance. *Temple.*

Their pensioner De Wit was a minister of the greatest authority and sufficiency ever known in their state. *Id.*

Thou king of horned floods, whose plenteous urn
Suffices fatness to the fruitful corn,
Shall share my morning song and evening vows. *Dryden.*

When the herd, sufficed, did late repair
To ferny heaths, and to the forest lair. *Id.*

The indolency we have, *sufficing* for our present happiness, we desire not to venture the change; being content ; and that is enough. *Locke.*

She would ruin me in silks, were not the quantity that goes to a large pincushion sufficient to make her a gown and petticoat. *Adlison.*

All to whom they are proposed, are by his grace sufficiently moved to attend and assent to them ; *sufficiently*, but not irresistibly ; for if all were irresistibly moved, all would embrace them ; and if none were sufficiently moved, none would embrace them. *Rogers.*

Seven months are a sufficient time to correct vice in a Yahoo. *Swift.*

The most proper subjects of dispute are questions not of the very highest importance, nor of the meanest kind ; but rather the intermediate questions between them ; and there is a large sufficiency of them in the sciences. *Watts's Imp. of the Mind.*

An elegant sufficiency, content. *Thomson.*

SUFFIELD, a post town of Hartford county, Connecticut, on the west bank of the Connecticut ; eleven miles south of Springfield, and seventeen north of Hartford. It is a pleasant and considerable town, and contains four houses of public worship, two for Congregationalists, and two for Baptists. Here is a mineral spring considerably resorted to.

SUFFISANCE, *n. s.* Fr. *suffisance*. Excess ; plenty. Obsolete.

There him rests in riotous suffisance
Of all gladfulness and kingly joyance. *Spenser.*

SUFFOCATE, *v. a.* } Fr. *suffoquer* ; Latin
SUFFOCATION, *n. s.* } *suffoco*. To choke by
SUFFOCATIVE, *adj.* } exclusion or interception of air : the act of choking or state of being choked : having the power to choke.

This chaos, when degree is suffocate,
Follows the choking. *Shakespeare. Troilus and Cressida.*

Diseases of stoppings and suffocations are dangerous. *Bacon.*

A swelling discontent is apt to suffocate and strangle without passage. *Collier of Friendship.*

Mushrooms are best corrected by vinegar ; some of them, being poisonons, operate by suffocation, in which the best remedy is wine or vinegar and salt, and vomiting as soon as possible. *Arbuthnot on Diet.*

From rain, after great frosts in the winter, glandulous tumours and suffocative catarrhs proceed. *Id. on Air.*

White consists in an equal mixture of all the primitive colours, and black in a suffocation of all the rays of light. *Cheyne.*

All involved in smoke, the latent foe
From every cranny suffocated falls. *Thomson.*

SUFFOLK, a maritime county of England, bounded north by Norfolk, west by Cambridgeshire, south by Essex, and on the east by the German Ocean. The river Stour divides it from Essex, the Little Ouse and Waveny from Norfolk, and the Great Ouse and its branches from Cambridgeshire. Its figure resembles a crescent, with the concavity towards the north, and the two horns projecting along the coast towards Yarmouth, and westward along the Ouse ; but an oblong of almost unindented form may be measured on its surface from east to west, forty-seven miles long, and thirty broad. Mr. Young estimates its area at 1269 square miles, or upwards of 800,000 acres. It contains from 150 to 160 inhabitants to each mile.

The two grand divisions are the liberty of Bury St. Edmund's, and what is termed the Body of the County, having each a separate grand jury. It is subdivided into twenty-one hun-

dreds and seventy-five parishes, which contain four boroughs, viz., Eye, Ipswich, Sudbury, and Bury St. Edmund's, and twenty-one other market towns, viz., Beccles, Bildeston, Brandon, Botesdale, Bungay, Clare, Debenham, Framlingham, Hadleigh, Haverhill, Ixworth, Lavenham, Lowestoff, Mendlesham, Mildenhall, Needham, Neyland, Saxmundham, Southwold, Stow Market, and Woodbridge. It sends thirteen members to parliament, viz., four for the county, one for Eye, and two for each of the other boroughs.

Suffolk is in general a level county, with few elevations; the highest part is in the west, where a great chalk ridge extends from Haverhill, by Bury, to Thetford, in Norfolk. This is sometimes called High Suffolk. The rivers, besides the Stour, Waveney, and Ouse, on the borders, are none of them of any magnitude, except perhaps the Orwell, which rises above Stow Market; and, under the name of Gipping, descends by Needham to Ipswich, where it becomes navigable, widens into an estuary, and then joins the Stour at Harwich. Other rivers are the Deben, Ald, and Blyth, along the coast, and the Lark on the west.

The *climate* is reckoned the driest in the kingdom: the frosts are severe, and north-east winds are in the spring sharp and prevalent. The soil of this county is very distinctly marked into 1st, a strong loam or a clay marl bottom pervading the centre and greatest part of the county, from Haverhill to Beccles on the one hand, and from near Ipswich to beyond Ixworth on the other. 2d, On the east, and between the former and the coast, extending northwards of the river Orwell, a district of sandy soil, and southwards a much smaller one of rich loam. 3d, To the west again occurs a considerable district of sand, which extends to the north-west corner of the county, where a fourth track of fen land is included between the Great and Little Ouse. The loam in the middle of the county is of a clayey nature, and highly productive, but varies in different places, more particularly along the banks of the rivers and streams, where it becomes a rich friable loam of superior quality. The sandy district along the coast varies from pure sand to loamy sand, and rests on a substratum of sand chalk, or a shell marl, termed here *crag*, which is found in great masses in various parts of the county. This is one of the best cultivated districts in England, and abounds with wealthy farmers. Besides its arable land, it contains heaths, which afford extensive sheep walks, and marshes covered with cattle. The sea shore is composed of cliffs, which are continually falling down by the action of the waves. The soil of the fens is composed, from one to six feet under the surface, of peat bog: part of the land is under water, but a good deal has been drained.

Suffolk is almost solely an agricultural county. The largest estate is supposed not to exceed £9000 a year; and of the smaller estates, which are very numerous, many are occupied by the proprietors. The size of farms is in general large: but the farm houses, much improved of late years, are still too often built of lath and

plaster. The common crops are wheat, barley, oats, rye, beans, pease, buck-wheat, cole-seed, turnips, clover, trefoil, white clover, and sainfoin. Buck-wheat forms a very valuable crop on sandy soils, and is more common here, even on the poorest, than in most other parts of England. Cole-seed is one of the principal productions of the fens. The culture of turnips prevails greatly: various other crops are raised in particular spots. A district called the Sandlands, lying between Woodbridge, Saxmundham, and Orford, is famous for its carrots, which have been raised here in great quantities for upwards of two centuries, and formerly used to supply the London market. Hops are raised in small quantity at Stow Market and in the neighbourhood, and cabbages for cows on the heavier land. Hemp is raised in a district about ten miles in breadth, extending from Eye to Beccles. It is woven on the spot into cloth of various degrees of fineness. Lucerne and chicory are also raised.

The management of arable land, and the courses of crops, vary considerably in the different districts. In strong soils the best rotation is, first fallow, second wheat, third beans, fourth barley, fifth clover, and sixth wheat. On the rich loam and sand, the most usual course is, first turnip, second barley, third clover, and fourth wheat. On the said districts, turnips are every where the preparative, both for corn and grass. In the fenny district cole-seed is usually sown after paring and burning; and, after two successive oat crops, the land is laid down in grass for six years. Several new agricultural implements have been introduced into this county. Irrigation is very little practised.

The dairy district lies near Framlingham, and extends about twenty miles by twelve; but the late high price of corn induced the ploughing up of a great quantity of pasture. The butter made is chiefly used in this and the adjoining county of Essex. Much cheese is also made; but is of an inferior quality. Suffolk cows have long been celebrated for their milk, which, in proportion to the quantity of food, and size of the animal, exceeds that of any other kind in the kingdom. They are all of the hornless or polled breed. The best milkers are in general red, brindled, or of a yellowish cream color. They yield from four to six gallons a day. The practice of feeding them on cabbages, once universal, is now on the decline. In some parts of the county black cattle are bought from north country drovers, to eat up the turnips. After being fattened, these are sent to the metropolis. The sheep, of which large flocks are kept in the county, were, till of late years, almost entirely of the Norfolk breed. The South Down, however, which were introduced by Mr. Young, are now very prevalent, and, from their superior qualities, have superseded the former.

Suffolk is no less noted for its horses than for its cows. These are found in the highest perfection in the maritime district, extending to Woodbridge, Debenham, Eye, and Lowestoff. Of hogs, the short white breed in the cow district has great merit. Poultry is kept here in abundance, and great quantities of pigeons are reared in the open field. Suffolk contains also

many rabbit warrens. One near Brandon is reckoned to return about 40,000 rabbits in a year. Of late years, however, considerable tracks occupied by them have been converted into arable and pasture land. Mr. Young estimates the waste lands in this county at 100,000 acres, comprehending sheep walk, commons, warrens, &c.; most of which are capable of improvement. It contains few woods or plantations of consequence. The commerce and manufactures of Suffolk have been long on the decline, and are inconsiderable. Corn and malt are the principal exports, and the imports are for the supply of the county with the articles of ordinary consumption. Lowestoff is noted for its herring fishery. The spinning and carding of wool was formerly carried on to a great extent, but this has been of late in a great measure transferred to Yorkshire. At Sudbury, one of the first seats of the Flemings, there is a manufactory of serges, and a small silk manufactory. Some calimancoes are still made at Lavenham. At the time of the Roman invasion, Suffolk belonged to the Tienne, and afterwards formed a part of the province of Flavia Cæsariensis.

SUFFOLK, a county of New York, on the east part of Long Island, bounded north by Long Island Sound, east and south by the Atlantic, and west by King's county. It comprises about two-thirds of the island. Chief towns, Riverhead, Sag Harbour, Satauket, and Huntington.

SUFFRAGAN, *n. s.* Fr. *suffragant*; Latin *suffraganeus*. A bishop considered as subject to his metropolitan.

The four archbishops of Mexico, Lima, S. Foy, and Dominico, have under them twenty-five *suffragan* bishops, all liberally endowed and provided for.

Heylyn.

Becket, archbishop of Canterbury, insolently took upon him to declare five articles void, in his epistle to his *suffragans*.

Hale.

Suffragan bishops shall have more than one riding apparitor.

Ayliffe's Parergon.

SUFFRAGAN is likewise the appellation given to a bishop who is occasionally appointed to reside in a town or village, and assist the diocesan.

SUFFRAGE, *n. s.* } French *suffrage*; Latin
SUFFRAGATE, *v. n.* } *suffragium*. Vote; voice given in a controverted point: to vote or agree with.

Noble confederates, thus far is perfect,
Only your *suffrages* I will expect
At the assembly for the chusing of consuls.

Ben Jonson.

No tradition could universally prevail, unless there were some common congruity of somewhat inherent in nature, which suits and *suffragates* with it, and closeth with it.

Hale.

Fabius might joy in Scipio, when he saw
A beardless consul made against the law;
And join his *suffrage* to the votes of Rome.

Dryden.

The fairest of our island dare not commit their cause to the *suffrage* of those who most partially adore them.

Addison.

Lactantius and St. Austin confirm by their *suffrage* the observation made by the heathen writers.

Atterbury.

To the law and to the testimony let the appeal be in the first place; and next to the united *suffrage* of the

primitive churches, as the best and safest commer^t upon the other.

Waterland.

SUFFRAG'INOUS, *adj.* L.at. *suffrago*. Belonging to the knee joint of beasts.

In elephants, the bought of the forelegs is not directly backward, but laterally, and somewhat inward; but the hough, or *suffraginous* flexure behind, rather outward.

Broune.

SUFFRUTEX, among botanists, denotes an undershrub, or the lowest kind of woody plants, as lavender.

SUFFUMIGE, *n. s.* Latin *suffumigo*. A medical fume. Not used.

For external means, drying *suffumiges* or smoaks, are prescribed with good success; they are usually composed out of frankincense, myrrh, and pitch.

Harvey.

If the matter be so gross as it yields not to remedies, it may be attempted by *suffumigation*.

Wiseman's Surgery.

SUFFUSE, *v. a.* } Lat. *suffusus*. To spread
SUFFUSION, *n. s.* } over with something ex-
pansible, as with a vapour or a tincture: the
noun substantive corresponding.

A drop serene hath quenched their orbs,
Or dim confusion veiled.

Milton.

The disk of Phœbus, when he climbs on high,
Appears at first but as a bloodshot eye;

And, when his chariot downward draws to bed,
His ball is with the same *suffusion* red.

Dryden.

Suspicious, and fantastical surmise,
And jealousy *suffused* with jaundice in her eyes.

Id.

To those that have the jaundice, or like *suffusion*
of eyes, objects appear of that color.

Ray.

To that recess,

When purple light shall next *suffuse* the skies,
With me repair.

Pope.

Instead of love-enlivened cheeks,
With flowing rapture bright, dark looks succeed,
Suffused and glaring with untender fire.

Thomson.

SUG, *n. s.* Lat. *sugo*, to suck. A kind of lice.

Many have sticking on them *sugs*, or trout-lice, which is a kind of worm like a clove or pin, with a big head, and sticks close to him, and sucks his moisture.

Walton.

SUGAR, *n. s. & v. a.* } Fr. *sucre*; Lat. *sac-*
SUG'ARY, *adj.* } *charum*. The native
salt of the sugar-cane. See below. Any thing
proverbially sweet; a dry chemical crystallisa-
tion: to impregnate with sugar; sweeten: sug-
gary is abounding with sugar.

All the blood of Zelmene's body stirred in her, as
wine will do when *sugar* is hastily put into it.

Sidney.

With the *suggary* sweet thereof allure
Chaste ladies' ears to phantasies impure.

Spenser.

Your fair discourse has been as *sugar*,
Making the hard way sweet and delectable.

Shakspeare.

Thou would'st have plunged thyself
In general riot, and never learned

The icy precepts of respect, but followed
The *sugared* game before thee.

Id. Timon

His glossing siren his errand daily said,

And *sugared* speeches whispered in mine ear.

Fairfax.

Lumps of *sugar* loose themselves, and twine
Their subtle essence with the soul of wine.

Crusans.

Who casts out threats, no man deceives,
But flattery still in *sugared* words betrays,
And poison in high-tasted meats conveys. *Denham.*

Sugar of lead, though made of that insipid metal,
and sour salt of vinegar, has in it a sweetness surpassing that of common *sugar*. *Boyle.*

If the child must have *sugar-plums* when he has a mind, rather than be out of humour; why, when he is grown up, must he not be satisfied too with wine? *Locke.*

Saccharum candidum shoots into angular figures, by placing a great many sticks a-cross a vessel of liquid *sugar*. *Greus.*

SUGAR. From the few remains of the Grecian and Roman authors which have survived the ravages of time, we can find no proofs that the juice of the sugar-cane was known at a very early period. There can be no doubt, however, that in those countries where it was indigenous its value was not long concealed. It is not improbable that it was known to the ancient Jews; for there is some reason to suppose, that the Hebrew word *קנה*, which occurs frequently in the Old Testament, and is by our translators rendered sometimes *calamus* and sometimes *sweet-cane*, does in fact mean the sugar-cane. The sugar-cane was first made known to the western parts of the world by the conquests of Alexander the Great. Strabo relates that Nearchus his admiral found it in the East Indies A. A. C. 325. It is evidently alluded to in a fragment of Theophrastus, preserved in Photius. Varro, who lived A. C. 68, describes it in a fragment quoted by Isidorus, as a fluid pressed from reeds of a large size, which was sweeter than honey. Dioscorides, about A. A. C. 35, says, 'that there is a kind of honey called *saccharon*, which is found in India and Arabia Felix. It has the appearance of salt, and is brittle when chewed. If dissolved in water, it is beneficial to the bowels and stomach, is useful in diseases of the bladder and kidneys, and, when sprinkled on the eye, removes those substances that obscure the sight.' This is the first account we have of its medical qualities. Galen often prescribed it as a medicine. Lucan relates that an oriental nation in alliance with Pompey used the juice of the cane as a common drink. Pliny says it was produced in Arabia and India, but that the best came from the latter country. It is also mentioned by Arrian, in his *Periplus of the Red Sea*, by the name of *Σαχαρ* (*sachar*) as an article of commerce from India to the Red Sea. Ælian, Tertullian, and Alexander Aphrodisæus, mention it as a species of honey procured from canes.

The sugar-cane, or *saccharum officinarum* of botanists, is a jointed reed, commonly measuring (the flag part not included) from three and a half to seven feet in height, but sometimes rising to twelve feet. When ripe it is of a fine straw color, inclining to yellow, producing leaves or blades, the edges of which are finely and sharply serrated, and terminating in an arrow decorated with a panicle. The joints in one stalk are from forty to sixty in number, and the stalks rising from one root are sometimes very numerous. The young shoot ascends from the earth like the point of an arrow; the shaft of which soon breaks, and the first two leaves, which had been

enclosed within a quadruple sheath of seminal leaves, rise to a considerable height. 'A field of canes, when standing, in November, when it is in arrow or full blossom,' says Mr. Beckford in his account of Jamaica, 'is one of the most beautiful productions that the pen or pencil can possibly describe. It in common rises from three to eight feet or more in height; a difference of growth that very strongly marks the difference of soil or the varieties of culture. It is when ripe of a bright and golden yellow; and, where obvious to the sun, is in many parts very beautifully streaked with red; the top is of a darkish green; but the more dry it becomes, from either an excess of ripeness or a continuance of drought, of a russet yellow, with long and narrow leaves depending; from the centre of which shoots up an arrow like a silver wand from two to six feet in height; and from the summits of which grows out a plume of white feathers, which are delicately fringed with a lilac dye; and indeed is, in its appearance, not much unlike the tuft that adorns this particular and elegant tree.'

That the sugar-cane is an indigenous plant of the East Indies we have the strongest reason to believe; for Thunberg found it in Japan, and has mentioned it as a native of that country in his *Flora Japonica*, published in 1784. Osbeck also found it in China in 1751. Marco Paolo, a noble Venetian, who travelled into the east about 1250, found sugar in abundance in Bengal. Vasco de Gama, who doubled the Cape of Good Hope in 1497, relates that a considerable trade in sugar was then carried on in the kingdom of Calicut. Dioscorides and Pliny, say that it is a native of Arabia; but Niebuhr, in his *Travels*, has omitted it when enumerating the most valuable plants of that country. Mr. Bruce found it in Upper Egypt. John Lioni says that a considerable trade was carried on in sugar in Nubia, in 1500; it abounded also at Thebes, on the Nile, and in the northern parts of Africa, about the same period. There is reason to believe that the sugar-cane was introduced into Europe during the crusades. Peter Martyr, in the third book of his first decade, composed during Columbus's second voyage, between 1493 and 1495, says that the sugar-cane was then known in Hispaniola. There are authors who maintain that it is a native both of the islands and of the continent of America; and that it is not for the plant itself, but for the secret of making sugar from it, that the West Indies are indebted to the Spaniards and Portuguese; and these to the nations of the east.

As the cane is a rank succulent plant, it requires a strong deep soil to bring it to perfection. The soil most favorable to the cultivation of it is the dark gray loam of St. Christopher's, which is so light and porous as to be penetrable by the slightest application of the hole. The under stratum is gravel from eight to twelve inches deep. Canes planted in particular spots in this island have yielded 8000 lbs. of Muscovado sugar from a single acre. The average produce of the island for a series of years has been 16,000 hogsheads of 16 cwt., which is one-half of the whole cane-land, or 8500 acres. When

annually cut, it gives nearly two hogsheads of 16 cwt. per acre, for the whole of the land in ripe canes. Next to the ashy loam of St. Christopher's is the soil which in Jamaica is called brick-mould; not as resembling a brick in color, but as containing such a due mixture of clay and sand as is supposed to render it well adapted for the use of the kiln. It is a deep, warm, and mellow, hazel earth, easily worked; and, though its surface soon grows dry after rain, the under stratum retains a considerable degree of moisture in the driest weather; with this advantage, too, that even in the wettest season it seldom requires trenching. Plane-canes, or canes of the first growth, have in very fine seasons yielded two tons and a half of sugar per acre. After this may be reckoned the black mould of several varieties. The best is the deep black earth of Barbadoes, Antigua, and some other of the windward islands; but there is a species of this mould in Jamaica that is but little, if any thing, inferior to it, which abounds with limestone and flint on a substratum of soapy marle. Black mould on clay is more common; but as the mould is generally shallow, and the clay stiff and retentive of water, this last sort of land requires great labour, both in ploughing and trenching, to render it profitable. When manured, and properly pulverised, it becomes very productive. There is a peculiar sort of land on the north side of Jamaica, chiefly in the parish of Trelawney, remarkable, not only on account of its scarcity, but its value; few soils producing finer sugars, or such as answer so well in the pan; an expression signifying a greater return of refined sugar than common. This land is of a red color; the shades however, vary considerably from a deep chocolate to a rich scarlet; in some places it approaches to a bright yellow, but it is every where remarkable for a glossy surface, and, if wetted, stains the fingers like paint. It is of great importance that the plants for seed be put into the ground at the commencement of this season. As the cane requires a great deal of moisture to bring it to maturity, the properest season for planting it is in September and October when the autumnal rains commence, and that it may be sufficiently luxuriant to shade the ground before the dry weather sets in. Thus the root is kept moist, and the crop is ripe for the mill in the beginning of the next year. Canes planted in November, or later, lose the advantage of the autumnal rains; and dry weather in the beginning of the year retards their vegetation until the May rains set in, when they sprout both at the roots and the joints; so that by the time they are cut, the field is loaded with unripe suckers instead of sugar-canes. A January plant, however, commonly turns out well; but canes planted very late in the spring, though they have the benefit of the May rains, seldom answer expectation; for they generally come in unseasonably, and throw the succeeding crops out of regular rotation. They are therefore often cut before they are ripe; or, if the autumnal seasons set in early, are cut in wet weather, which has probably occasioned them to spring afresh: in either case the effect is the same. The juice is unconcocted, and, all the sap being in motion, the root is de-

prived of its natural nourishment, to the great injury of the ratoon. The chief objection to a fall plant is this, that the canes become rank and top heavy, at a period when violent rains and high winds are expected, and are therefore frequently lodged before they are fit to be cut. The sugar-cane is propagated by the top shoots, which are cut from the tops of the old canes. The usual method of planting in the West Indies is this:—The quantity of land intended to be planted, being cleared of weeds and other incumbrances, is first divided into several plats of certain dimensions, commonly from fifteen to twenty acres each; the spaces between each plat or division are left wide enough for roads, for the conveniency of carting, and are called intervals. Each plat is then subdivided, by a line and wooden pegs, into small squares of about three and a half or four feet. The negroes are then placed in a row in the first line, one to a square, and directed to dig out with their hoes the several squares, to the depth of five or six inches. The mould which is dug up being formed into a bank, at the lower side, the excavation or cane-hole seldom exceeds fifteen inches in width at the bottom, and two feet and a half at the top. The negroes then fall back to the next line, and proceed as before. Thus the several squares between each line are formed into a trench of much the same dimensions with that which is made by the plough. An able negro will dig from 100 to 120 of these holes for his day's work of ten hours; but, if the land has been previously ploughed and lain fallow, the same negro will nearly double the number in the same time. The cane-holes or trench being now completed, whether by the plough or by the hoe, and the cuttings selected for planting, which are commonly the tops of the canes that have been ground for sugar (each cutting containing five or six gems), two of them are sufficient for a cane-hole of the dimensions described. These, being placed longitudinally in the bottom of the hole, are covered with mould about two inches deep; the rest of the bank being intended for future use. In twelve or fourteen days the young sprouts begin to appear; and, as soon as they rise a few inches above the ground, they are carefully cleared of weeds, and furnished with an addition of mould from the banks. This is usually performed by the hand. At the end of four or five months the banks are wholly levelled, and the spaces between the rows carefully hoe-ploughed. Frequent cleanings, while the canes are young, are indeed essentially necessary. A careful manager will remove all the lateral shoots or suckers that spring up after the canes begin to joint, as they seldom come to maturity, and draw nourishment from the original plants. In the cultivation of other lands, in Jamaica especially (says Mr. Edwards, the elegant historian of the West Indies), the plough has been introduced of late years, and in some few cases to great advantage: but it is not every soil or situation that will admit the use of the plough; some lands being much too stony and others too steep. The only advantageous system of ploughing in the West Indies is to confine it to the

simple operation of holing, which may be performed with much greater facility by the plough than by the hoe; and the relief which, in the case of stiff and dry soils, is thus given to the negroes, exceeds all estimation, in the mind of a humane owner. At a plantation of my own, the greatest part of the land which is annually planted is neatly and sufficiently laid into caneholes, by the labor of one able man, three boys, and eight oxen, with the common single-wheeled plough. The plough-share indeed is somewhat wider than usual: but this is the only difference, and the method of ploughing is the simplest possible. By returning the plough back along the furrow, the turf is alternately thrown to the right and to the left, forming a trench seven inches deep, about two feet and a half wide at the top, and one foot wide at the bottom. A space of eighteen or twenty inches is left between each trench, on which the mould being thrown, by the share, the banks are properly formed, and the holing is complete. Thus the land is not exhausted by being too much exposed to the sun; and a field of twenty acres is thus holed with one plough, and with great ease, in thirteen days. The plants are afterwards placed in the trench as in the common method where manual labor is alone employed. In most parts of the West Indies it is usual to hole and plant a certain proportion of the cane land, commonly one-third, in annual rotation. The sprouts that spring from the roots of the canes that have been previously cut for sugar are called ratoons; the first yearly returns from their roots are called first ratoons; the second year's growth second ratoons. Mr. Edwards informs us that the manure generally used is a compost, formed, 1st, Of the vegetable ashes drawn from the fires of the boiling and still houses. 2dly, Feculencies discharged from the still-house, mixed up with rubbish of buildings, white lime, &c. 3dly, Refuse, or field-trash, i. e. the decayed leaves and stems of the canes; so called in contradistinction to cane-trash, reserved for fuel. 4thly, Dung, obtained from the horse and mule stables, and from moveable pens, or small enclosures made by posts and rails, occasionally shifted upon the lands intended to be planted, and into which the cattle are turned at night. 5thly, Good mould, collected from gullies and other waste places, and thrown into the cattle-pens.

The sugar-cane is liable to be destroyed by monkeys, rats, and insects. The upland plantations suffer greatly from monkeys; these creatures, which now abound in the mountainous parts of St. Christopher's, were first brought thither by the French, when they possessed half that island; they come down from the rocks in silent parties by night; and, having posted sentinels, to give the alarm if any thing approaches, they destroy incredible quantities of the cane, by their gambols as well as their greediness. It is in vain to set traps for these creatures, however baited; and the only way to protect the plantation, and destroy them, is to set a numerous watch, well armed with fowling-pieces, and furnished with dogs. The negroes will perform

this service cheerfully, for they are very fond of monkeys as food. Labat says they are very delicious, but the white inhabitants of St. Kitt's never eat them. The lowland plantations suffer as much by rats as those on the mountains do from monkeys; they also came with the shipping from Europe, and breed in the ground under loose rocks and bushes; the field negroes eat them greedily, and they are said to be publicly sold in the markets at Jamaica. To free the plantations from these vermin, the breed of wild cats should be encouraged, and snakes suffered to multiply unmolested; they may also be poisoned with arsenic, and the rasped root of the cassava, made into pellets and plentifully scattered over the grounds. This practice, however is dangerous; for, as the rats when thus poisoned become exceedingly thirsty, they run in droves to the neighbouring streams, which they poison as they drink, and the cattle grazing on the banks of these polluted waters have frequently perished by drinking after them. It is safer therefore to make the pellets of flour, kneaded with the juice of the night-shade, the scent of which will drive them away though they will not eat it. There is an East Indian animal called mungoes, which bears a natural antipathy to rats; if this animal were introduced into our sugar islands it would probably extirpate the whole race of these noxious vermin. The formica omnivora of Linnæus, the carnivorous ant, which is called in Jamaica the raffle's ant, would soon clear the sugar plantations of rats. The sugar-cane is also subject to a disease which no foresight can obviate, and for which human wisdom has in vain attempted to find a remedy. This disease is called the blast, and is occasioned by the aphid of Linnæus. When this happens, the fine broad green blades become sickly, dry, and withered; soon after they appear stained in spots; and, if these spots are carefully examined, they will be found to contain innumerable eggs of an insect like a bug, which are soon quickened, and cover the plants with the vermin; the juice of the canes thus affected becomes sour, and no future shoot issues from the joints. Ants also concur with the bugs to spoil the plantation, and against these evils it is hard to find a remedy.

The crops of sugar-canes do not ripen precisely at the same period in all the colonies. In the Danish, Spanish, and Dutch settlements they begin in January and continue till October. This method doth not imply any fixed season for the maturity of the sugar-cane. The plant, however, like others, must have its progress; and it has been justly observed to be in flower in the months of November and December. It must necessarily follow, from the custom these nations have adopted of continuing to gather their crops for ten months without intermission, that they cut some canes which are not ripe enough, and others that are too ripe, and then the fruit has not the requisite qualities. The time of gathering them should be at a fixed season, and probably the months of March and April are the fittest for it; because all the sweet fruits are ripe at that time, while the sour ones do not arrive to a state of maturity till the

months of July and August. The English cut their canes in March and April; but they are not induced to do this on account of their ripeness. The drought that prevails in their islands renders the rains which fall in September necessary to their planting; and, as the canes are eighteen months in growing, this period always brings them to the precise point of maturity. 'The time of crop in the sugar islands,' says Mr. Edwards, is the season of gladness and festivity to man and beast. So palatable, salutary, and nourishing, is the juice of the cane, that every individual of the animal creation, drinking freely of it, derives health and vigor from its use. The meagre and sickly among the negroes exhibit a surprising alteration in a few weeks after the mill is set in action. The laboring horses, oxen, and mules, though almost constantly at work during this season, yet, being indulged with plenty of the green tops of this noble plant, and some of the scummings from the boiling house, improve more than at any other period of the year. Even the pigs and poultry fatten on the refuse. In short, on a well regulated plantation, under a humane and benevolent director, there is such an appearance during crop-time of plenty and busy cheerfulness, as to soften in a great measure the hardships of slavery.'

The plants being cut, the branches at the top are given to the cattle for food; the top shoot, which is full of eyes, is preserved for planting. The canes are cut into pieces about a yard long, tied up in bundles, and carried in carts to the mill, where they are bruised and the juice is extracted from them. The mill consists principally of three upright iron-plated rollers or cylinders, from thirty to forty inches in length, and from twenty to twenty-five inches in diameter; and the middle one, to which the moving power is applied, turns the other two by means of cogs. Between these rollers the canes (being previously cut short and tied into bundles) are twice compressed; for, having passed through the first and second rollers, they are turned round the middle one by a circular piece of frame-work or screen, called in Jamaica the dumb returner, and forced back through the second and third; an operation which squeezes them completely dry, and sometimes even reduces them to powder. The cane-juice is received in a leaden bed, and thence conveyed into a vessel called the receiver. The refuse or macerated rind of the cane (which is called cane-trash, in contradistinction to field-trash), serves for fuel to boil the liquor. The juice as it flows from the mill, taken at a medium, contains eight parts of pure water, one part of sugar, and one part consisting of coarse oil and mucilaginous gum, with a portion of essential oil. As this juice has a strong disposition to fermentation, it must be boiled as soon as possible. There are some water mills that will grind with great ease canes sufficient for thirty hogsheads of sugar in a week. It is necessary to have boiling vessels, or clarifiers, that will correspond in dimensions to the quantity of juice flowing from the receiver. These clarifiers

are commonly three in number, and are sometimes capable of containing 1000 gallons each; but it is more usual to see them of 300 or 400 gallons each. Besides the clarifiers which are used for the first boiling there are generally four coppers or boilers. The clarifiers are placed in the middle or at one end of the boiling house. If at one end, the boiler called the teache is placed at the other, and several boilers (generally three) are ranged between them. The teache is ordinarily from seventy to 100 gallons, and the boilers between the clarifiers and teache diminish in size from the first to the last. Where the clarifiers are in the middle, there is usually a set of three boilers on each side, which constitute in effect a double boiling house. On very large estates this arrangement is found useful and necessary. The objection to so great a number is the expense of fuel, to obviate which, in some degree, the three boilers on each side of the clarifiers are commonly hung to one fire. The juice runs from the receiver along a wooden gutter lined with lead into the boiling house, where it is received into one of the clarifiers. When the clarifier is filled, a fire is lighted, and a quantity of Bristol quicklime in powder, which is called temper, is poured into the vessel. The use of the lime is to unite with the superabundant acid, which, for the success of the process, it is necessary to get rid of. The quantity sufficient to separate the acid must vary according to the strength of the quicklime and the quality of the liquor. Some planters allow a pint of lime to every 100 gallons of liquor; but Mr. Edwards thinks that little more than half the quantity is a better medium proportion; and even then that it ought to be dissolved in boiling water, that as little of it as possible may be precipitated. The heat is suffered gradually to increase till it approaches within a few degrees of the heat of boiling water, that the impurities may be thoroughly separated. But, if the liquor were suffered to boil with violence, the impurities would again incorporate with it. It is known to be sufficiently heated when the scum begins to rise in blisters, which break into white froth, and appear generally in about forty minutes. The fire is then suddenly extinguished by means of a damper, which excludes the external air, and the liquor is allowed to remain about an hour undisturbed, during which period the impurities are collected in scum on the surface. The juice is then drained off, either by a syphon or a cock; the scum, being of a tenacious gummy nature, does not flow out with the liquor, but remains behind in the clarifier. The liquid juice is conveyed from the clarifier by a gutter into the evaporating boiler, commonly termed the grand copper; and, if it has been obtained from good canes, it generally appears transparent. In the evaporating boiler, which should be large enough to receive the contents of the clarifier, the liquor is allowed to boil; and as the scum arises it is taken off. The scumming and evaporation are continued till the liquor becomes finer and thicker, and so far diminished in bulk that it may be easily contained in the second copper. When put into the second copper, it

is nearly of the color of Madeira wine; the boiling and scumming are continued; and, if the impurities be considerable, a quantity of lime-water is added. This process is carried on till the liquor be sufficiently diminished in quantity to be contained in the third copper. After being purified a third time, it is put into the fourth copper, which is called the *teache*, where it is boiled and evaporated till it is judged sufficiently pure to be removed from the fire. In judging of the purity of the liquor, many of the negroes (says Mr. Edwards) guess solely by the eye (which, by long habit, they do with great accuracy), judging by the appearance of the grain on the back of the ladle: but the practice most in use is to judge by what is called the touch; i. e. taking up with the thumb a small portion of the hot liquor from the ladle; and, as the heat diminishes, drawing with the fore finger the liquid into a thread. This thread will suddenly break, and shrink from the thumb to the suspended finger, in different lengths, according as the liquor is more or less boiled. The proper boiling height for strong muscovado sugar is generally determined by a thread of a quarter of an inch long. It is evident that certainty in this experiment can be attained only by long habit, and that no verbal precepts will furnish any degree of skill in a matter depending wholly on constant practice. The juice being thus purified, by passing through the clarifier and four coppers, it is poured into coolers, which are usually six in number. The removal from the *teache* to the cooler is called *striking*. The cooler is a shallow wooden vessel, seven feet long, from five to six wide, about eleven inches deep, and capable of containing a hogshead of sugar. As the liquor cools, the sugar *grains*, that is, collects into an irregular mass of imperfect crystals, separating itself from the *melasses*. It is then removed from the cooler and conveyed to the curing-house, where the *melasses* drain from it. For receiving them there is a large cistern, the sloping sides of which are lined with boards. Directly above the cistern a frame of joist-work without boarding is placed, on which empty hogsheads without heads are ranged. The bottoms of these hogsheads are pierced with eight or ten holes, in each of which the stalk of a plantain leaf is fixed, so as to project six or eight inches below the joists, and rise a little above the top of the hogshead. The hogsheads being filled with the contents of the cooler, consisting of sugar and *melasses*, the *melasses* being liquid, drain through the spongy stalk, and drop into the cistern. After the *melasses* are drained off, the sugar becomes pretty dry and fair, and is then called muscovado or raw sugar. Such is the process for extracting sugar, which is generally adopted in the British West India Islands, according to the latest improvements.

The above is the method of cultivating and manufacturing sugar in the West Indies, where slaves alone are employed: but we feel a peculiar pleasure in having it in our power to add a short description of the method used in the East Indies, because there sugar is manufactured by free men, on a plan much more economical than what is followed in the West Indies. It is an

extract from the report of the committee of privy council for trade on the subject of the African slave-trade, drawn up by Mr. Botham. We give it in the author's own words. 'Having been for two years in the English and French West Indian islands, and since conducted sugar estates in the East Indies, before the abolition of the slave trade was agitated in parliament, it may be desirable to know that sugar of a superior quality and inferior price to that in our islands is produced in the East Indies; that the culture of the cane, the manufacture of the sugar and arrack, is, with these material advantages, carried on by free people. China, Bengal, the coast of Malabar, all produce quantities of sugar and spirits; but, as the most considerable growth of the cane is carried on near Batavia, I shall explain the improved manner in which sugar estates are there conducted. The proprietor of the estate is generally a wealthy Dutchman, who has erected on it substantial mills, boiling and curing houses. He rents this estate to a Chinese, who resides on it as a superintendent: and this renter (supposing the estate to consist of 300 or more acres) lets it to freemen in parcels of fifty or sixty, on these conditions: 'that they shall plant it in canes, and receive so much per pecul of 133½ lbs. for every pecul of sugar that the canes shall produce.' When crop time comes on the superintendent collects a sufficient number of persons, from the adjacent towns or villages, and takes off his crop as follows. To any set of tradesmen who bring their carts and buffaloes he agrees to give such a price per pecul to cut all his crop of canes, carry them to the mill, and grind them. A second to boil them per pecul. A third to clay them and basket them for market per pecul. So that by this method of conducting a sugar estate, the renter knows to a certainty what the produce of it will cost him per pecul. He has not any permanent or unnecessary expense; for, when the crop is taken off, the taskmen return to their several pursuits in the towns and villages they came from; and there only remains the cane planters who are preparing the next year's crop. This, like all other complex arts, by being divided into several branches, renders the labor cheaper, and the work more perfectly done. Only clayed sugars are made at Batavia; these are in quality equal to the best sort from the West Indies, and are sold so low from the sugar estates as eighteen shillings sterling per pecul of 133½ lbs. This is not the selling price to the trader at Batavia, as the government there is arbitrary, and sugar subject to duties imposed at will. The shabander exacts a dollar per pecul on all sugar exported. The price of common labor is from ninepence to tenpence per day. By the method of carrying on the sugar estates, the taskmen gain considerably more than this not only from working extraordinary hours, but from being considered artists in their several branches. They do not make spirits on the sugar estates. The *melasses* is sent for sale to Batavia, where one distillery may purchase the produce of 100 estates. Here is a vast saving and reduction of the price of spirits, not, as in the West Indies, a distillery for each estate; many centre in one, and arrack is sold in Batavia from twenty-one to

twenty-five six dollars per leaguer of 160 gallons; say eightpence per gallon.

The operation of the French sugar refiners consists in dissolving the cassonade, or clayed sugar, in lime-water. Bullocks' blood is added to promote the clarifying; and, when the liquor begins to boil, the heat is diminished, and the scum carefully taken off. It is in the next place concentrated by a brisk heat; and, as it boils up, a small quantity of butter is thrown in to moderate its agitation. When the boiling is sufficiently effected, the fire is put out; the liquor is poured into moulds and agitated, to mix the syrup together with the grain sugar already formed. When the whole is cold, the moulds are opened, and the loaves are covered with moistened clay, which is renewed from time to time till the sugar is well cleansed from its syrup. The loaves, being then taken out of the moulds, are carried to a stove, where they are gradually heated to 145° Fahrenheit. They remain in this stove eight days, after which they are wrapped in blue paper for sale.

The following is the method by which the French make their sugar purer and whiter than ours. A quantity of sugar from the cooler is put into conical pans or earthen pots, called by the French *formes*, having a small perforation at the apex, which is kept closed. Each cone, reversed on its apex, is supported in another earthen vessel. The syrup is stirred together, and then left to crystallise. At the end of fifteen or sixteen hours, the hole in the point of each cone is opened, that the impure syrup may run out. The base of these sugar loaves is then taken out, and white pulverised sugar substituted in its stead; which being well pressed down, the whole is covered with clay moistened with water. This water filters through the mass, carrying the syrup with it which was mixed with the sugar, but which by this management flows into a pot substituted in the place of the first. This second fluid is called *fine syrup*. Care is taken to moisten and keep the clay to a proper degree of softness as it becomes dry. The sugar loaves are afterwards taken out, and dried in a stove for eight or ten days; after which they are pulverised, packed, and exported to Europe, where they are still farther purified. The reason assigned why this process is not universally adopted in the British sugar islands is this, that the water which dilutes and carries away the melasses dissolves and carries with it so much of the sugar that the difference in quality does not pay for the difference in quantity. The French planters think otherwise.

The art of refining sugar was first made known to the Europeans by a Venetian, who is said to have received 100,000 crowns for the invention. This discovery was made before the new world was explored; but whether it was an invention of the person who first communicated it, or was conveyed from China, where it had been known before, cannot be ascertained. We find no mention made of the refining of sugar in Britain till 1659, though it probably was practised several years before. The sugar which undergoes the operation of refining in Europe is either raw sugar, sometimes called *muscovado*, or *cassonado*, which is raw sugar in a purer state. The raw sugar generally

contains a certain quantity of melasses as well as earthy and feculent substances. The *cassonado*, by the operation of earthing, is freed from its melasses. As the intention of refining these sugars is to give them a higher degree of whiteness and solidity, it is necessary for them to undergo other processes. The first of these is called *clarification*. It consists in dissolving the sugar in a certain proportion of lime water, adding a proper quantity of bullock's blood, and exposing it to heat in order to remove the impurities which still remain. The heat is increased very gradually, till it approach that of boiling water. By the assistance of the heat, the animal matter which was thrown in coagulates, at the same time that it attracts all the solid feculent and earthy matter, and raises it to the surface in the appearance of a thick foam of a brownish color. As the feculencies are never entirely removed by a first process, a second is necessary. The solution is therefore cooled to a certain degree, by adding some water; then a fresh quantity of blood, but less considerable than at first, is poured in. The fire is renewed, and care is taken to increase the heat gently as before. The animal substance seizes on the impurities which remain, collects them on the surface, and they are then skimmed off. The same operation is repeated a third and even a fourth time, but no addition is made to the liquor except water. If the different processes have been properly conducted, the solution will be freed from every impurity, and appear transparent. It is then conveyed by a gutter into an oblong basket about sixteen inches deep, lined with a woollen cloth; and, after filtering through this cloth, it is received in a cistern or copper, which is placed below. The solution being thus clarified, it undergoes a second general operation called *evaporation*. Fire is applied to the copper into which the solution was received, and the liquid is boiled till it has acquired the proper degree of consistency. A judgment is formed of this, by taking up a small portion of the liquid and drawing it into a thread. When, after this trial, it is found sufficiently viscous, the fire is extinguished, and the liquid is poured into coolers. It is then stirred violently by an instrument called an *oar*, resembling the oar of a boat. This is done to diminish the viscosity, and promote what is called the *granulation*, that is, the forming of it into grains or imperfect crystals. When the liquid is properly mixed and cooled, it is then poured into moulds of the form of a sugar loaf. The moulds are ranged in rows. The small ends, which are lowest, are placed in pots; and they have each of them apertures stopped up with linen for filtering the syrup, which runs from the moulds into the pots. The liquor is then taken out slowly in ladefuls from the coolers, and poured into the moulds. When the moulds are filled, and the contents still in a fluid state, it is necessary to stir them, that no part may adhere to the moulds, and that the small crystals which are just formed may be equally diffused through the whole mass. When the sugar is completely crystallised, the linen is taken away from the apertures in the moulds, and the syrup, or that part which did not crystallise, descends into the pots in which the moulds are placed. After this

purgation the moulds are removed and fixed in other pots, and a stratum of fine white clay diluted with water is laid on the upper part of the loaf. The water descending through the sugar by its own weight, mixes with the syrup which still remains in the body of the loaf, and washes it away. When the clay dries, it is taken off, and another covering of moist clay put in its place; and, if it be not then sufficiently washed, a third covering of clay is applied. After the loaves have stood some days in the moulds, and have acquired a considerable degree of firmness and solidity, they are taken out and carried to a stove, where they are gradually heated to the 50° of Reaumur (64° of Fahrenheit), in order to dissipate any moisture which may be still confined in them. After remaining in the stove eight days, they are taken out; and after cutting off all discolored specks, and the head if still wet, they are wrapped in blue paper, and are ready for sale. The several syrups collected during the different parts of the process, treated in the same manner which we have just described, afford sugars of inferior quality; and the last portion, which no longer affords any sugar, is sold by the name of melasses. The beauty of refined sugar, when

formed into loaves, consists in whiteness, joined to a smallness of grain; in being dry, hard, and somewhat transparent. The process which we have described above, refers to sugar once refined; but some more labor is necessary to produce double refined sugar. The principal difference in the operation is this, the latter is clarified by white of eggs instead of blood and fresh water in place of lime-water.

As the sugar-cane is the principal production of the West Indies, and the great source of their riches; as it is so important in a commercial view, from the employment which it gives to seamen, and the wealth which it opens for merchants; and besides is now become a necessary of life—it may justly be esteemed one of the most valuable plants in the world. The quantity consumed in Europe is estimated at £9,000,000 sterling, and the demand would probably be greater if it could be sold at a reduced price. In the Portuguese island of St. Thomas, in 1624, there were seventy-four sugar ingenios, each having upwards of 200 slaves.

An idea of the importance of this import at the present time may be found from the following parliamentary papers:—

From September 5th 1825 to January 5th 1826	1	19	7 $\frac{1}{2}$	do.	1 7 0 do.

There are several other vegetables raised in our own country which afford sugar; as beetroots, skirrets, parsnips, potatoes, celery, red cabbage stalks, &c., besides the shoots of Indian wheat. The sugar is most readily obtained from these by making a tincture of the subject in rectified spirit of wine; which, when saturated by heat, will deposit the sugar upon standing in the cold.

The uses to which sugar are applied are indeed numerous and important. It can be made so solid as in the art of preserving to receive the most agreeable colors and the greatest variety of forms. It can be made so fluid as to mix with any soluble substance. It preserves the juice and substance of fruits in all countries and in all seasons. It affords a delicious seasoning to many kinds of food. It is useful in pharmacy; for it unites with medicines and removes their disagreeable flavor. It is the basis of all syrups. M. Macquer has shown in a very satisfactory manner how useful sugar would be if employed in fermenting wines. Sugar has also been found a remedy for the scurvy, and a valuable article of food in cases of necessity. M. Jambert de Lennes, first surgeon to the late duke of Orleans, published the following story in the Gazette de Santé which confirms this assertion. A vessel laden with sugar bound from the West Indies was becalmed in its passage for several days, during which the stock of provisions was exhausted. Some of the crew were dying of the scurvy, and the rest were threatened with a still

more terrible death. In this emergency recourse was had to the sugar. The consequence was the symptoms of the scurvy went off, the crew found it a wholesome and substantial aliment, and returned in good health to France. 'Sugar (says Dr. Rush) affords the greatest quantity of nourishment in a given quantity of matter of any substance in nature; of course it may be preserved in less room in our houses, and may be consumed in less time, than more bulky and less nourishing aliment. It has this peculiar advantage, over most kinds of aliment, that it is not liable to have its nutritious qualities affected by time or the weather; hence it is preferred by the Indians in their excursions from home. They mix a certain quantity of maple sugar with an equal quantity of Indian corn, dried and powdered, in its milky state. This mixture is packed in little baskets, which are frequently wetted in travelling without injuring the sugar. A few spoonfuls of it mixed with half a pint of spring water afford them a pleasant and strengthening meal. From the degrees of strength and nourishment which are conveyed into animal bodies by a small bulk of sugar, it might probably be given to horses with great advantage, when they are used in places or under circumstances which make it difficult or expensive to support them with more bulky or weighty aliment. A pound of sugar with grass or hay has supported the strength and spirits of a horse during a whole day's labor in one of the West India islands. A larger quantity given alone has fattened horses

and cattle, during the war before last in Hispaniola, for a period of several months, in which the exportation of sugar, and the importation of grain, were prevented by the want of ships. The plentiful use of sugar in diet is one of the best preventatives that has ever been discovered of the diseases which are produced by worms. Nature seems to have implanted a love for this aliment in all children, as it were on purpose to defend them from those diseases. I knew a gentleman in Philadelphia who early adopted this opinion, and who, by indulging a large family of children in the use of sugar, has preserved them all from the diseases usually occasioned by worms. Sir John Pringle has remarked that the plague has never been known in any country where sugar composes a material part of the diet of the inhabitants. It is probable that the frequency of malignant fevers of all kinds has been lessened by this diet, and that its more general use would defend that class of people who are most subject to malignant fevers from being so often affected by them. In the numerous and frequent disorders of the breast, which occur in all countries where the body is exposed to a variable temperature of weather, sugar affords the basis of many agreeable remedies. It is useful in weaknesses, and acrid defluxions upon other parts of the body. Many facts might be adduced in favor of this assertion. Upon my enquiring of Dr. Franklin, at the request of a friend (says Dr. Rush), about a year before he died, whether he had found any relief from the pain of the stone from the blackberry jam, of which he took large quantities, he told me that he had; but that he believed the medicinal part of the jam resided wholly in the sugar; and, as a reason for thinking so, he added that he often found the same relief by taking about half a pint of syrup, prepared by boiling a little brown sugar in water, just before he went to bed, that he did from a dose of opium. It has been supposed by some of the early physicians of our country that the sugar obtained from the maple-tree is more medicinal than that obtained from the West India sugar-cane; but this opinion, I believe, is without foundation. It is preferable in its qualities to the West India sugar only from its superior cleanliness. Cases may occur in which sugar may be required in medicine, or in diet, by persons who refuse to be benefited, even indirectly, by the labor of slaves. In such cases the innocent maple sugar will always be preferred. It has been said that sugar injures the teeth; but this opinion now has so few advocates that it does not deserve a serious refutation.

Sugar is soluble in water, and in a small degree in alcohol. When united with a small portion of water, it becomes fusible; from which quality the art of preserving is indebted for many of its preparations. It is phosphoric and combustible; when exposed to fire emitting a blue flame if the combustion be slow, and a white flame if the combustion be rapid. By distillation it produces a quantity of phlegm, acid, oil, gas, and charcoal. Bergman, in treating sugar with the nitrous acid, obtained a new acid, now known by the name of the oxalic acid; but he omitted to mention the principles of

which sugar is composed. Lavoisier, however, supplied this omission; and after many experiments has assigned three principles in sugar, hydrogen, oxygen, and carbon. If the juice expressed from the sugar-cane be left to itself, it passes into the acetous fermentation; and during the decomposition of the sugar, which is continued for three or four months, a great quantity of glutinous matter is separated. This matter when distilled gives a portion of ammoniac. If the juice be exposed to the spirituous fermentation, a wine is obtained analogous to cyder. If this wine, after being kept in bottles a year, be distilled, we obtain a portion of eau de vie.

It appears that sugar has the property of rendering some of the earths soluble in water. This property was accidentally discovered by Mr. William Ramsay, of Glasgow. Being employed in making experiments on sugar, and happening to put some quicklime into a cold solution of it, he noticed that it had acquired an uncommon caustic taste. Hence he concluded that sugar possesses the property of dissolving a certain proportion of lime; and, in order to ascertain its capacity in this respect, experiments were made upon this earth, together with strontites, magnesia, and barytes.

Sugar, dissolved in water at the temperature of 50°, is capable of dissolving one-half of its weight of lime. The solution of lime in sugar is of a beautiful white-wine color, and has the smell of fresh-slaked quicklime. It is precipitated from the solution by the carbonic, citric, tartaric, sulphuric, and oxalic acids; and it is decomposed by double affinity, by caustic and carbonated potash and soda, the citrate, tartrate, and oxalate of potash, &c.

An equal weight of strontia, with the sugar employed, is capable of being dissolved at the temperature of 212°, and of being retained in solution by the sugar at 50° of Fahrenheit. On exposing the crystals, which had fallen down during the cooling of the liquid, to the air of the atmosphere, they attracted carbonic acid, and effloresced.

The solution of strontia in sugar is of a fine white-wine color, and, like that of lime, has a peculiar caustic smell. This earth is precipitated by caustic and carbonated potash and soda; also by the carbonic, citric, tartaric, sulphuric, and oxalic acids; and it is decomposed, by compound affinity, by the carbonates of potash and soda; also by the citrate, tartrate, and oxalate of potash.

The solution of magnesia in syrup, like those of lime and strontia, was of a pure white color, and had no sensible variation in smell or taste from the common solution of sugar, farther than that the sweet seemed much improved, and was softer and more agreeable to the palate, as if it were entirely freed from the earthy taste which unrefined sugar frequently has. On its remaining at rest for some months, in a bottle well corked, the magnesia appears to be entirely separated. Very little alumina is dissolved by a solution of sugar, when fresh precipitated earth is presented to it, either in the cold or hot state.

The union of sugar with the alkalis has been long known; but this is rendered more strikingly evident, by carbonated potash or soda, for in-

stance, decomposing the solutions of lime and strontia in sugar, by double affinity. The power possessed by tartaric acid of preventing the precipitation of iron and some other metals from their muriatic solution, is well known from the observations of M. Rose and others. A similar effect is produced by sugar, according to M. Peschier, if the mixture be boiled, but not otherwise.—Ann. de Chim. et Phys. xxxi. 197.

In making solutions of unrefined sugar for culinary purposes, a gray-colored substance is found frequently precipitated. It is probable that this proceeds from a superabundance of lime, which has been used in clarifying the juice of the sugar-cane at the plantations abroad. Sugar with this imperfection is known among the refiners of this article by the name of *weak*. And it is justly termed so, the precipitated matter being nothing but lime which has attracted carbonic acid from the sugar (of which there is a great probability), or from the air of the atmosphere. A bottle in which I had kept a solution of lime in sugar for at least four years, closely corked, was entirely incrustated with a yellowish-colored matter, which on examination was found to be entirely carbonate of lime.

In the ordinary refining of raw sugars, from twenty to thirty-five per cent. of melasses are separated, of which a considerable part, probably two-thirds, are formed by the high heat used in the concentration of the syrup. Various plans have been contrived to diminish this production of melasses. One of these consisted in surrounding the sugar boiler with oil or steam at a high temperature, instead of exposing it to a naked fire. In a second, the boiler is covered at top, and by means of an air-pump the atmospheric pressure is removed, so as to favor ebullition, and rapid evaporation, at moderate heats.

The celebrated chemist, Mr. Howard, took out a patent for his plan, which is undoubtedly the most scientific and productive of any; but requires superior skill and very minute attention in the manufacturer. No blood is used for clarification. This is accomplished by a system of most ingenious canvass filters, aided by the intermixture with the syrup of a small quantity of pasty gypsum and alumina, made by saturating a solution of alum with quicklime. In the final purification the base of the inverted sugar cone is covered with a stratum of very pure saturated syrup, instead of moist pipe-clay.

The third method is founded on the property which animal charcoal (bone-black) possesses, of destroying vegetable coloring matter. Perhaps the combination of the last two modes promises the best results.

A fourth process for refining sugar is that of Mr. Daniel Wilson, for which a patent was granted. The specification is in the thirty-fourth volume of the Repertory, p. 134. The pan is to be charged with strong lime-water, the sugar added, and the fire set in the usual manner. For every hundred weight of sugar used, a solution is to be made of four ounces of sulphate of zinc as small a quantity of water as will dissolve it. When the sugar in the pan is melted, the solution of sulphate of zinc is added, and the whole well stirred. The oxide of zinc combines with

the extractive matter, tannin, and gallic acid, and renders them insoluble, while the sulphuric acid, in combination with the lime, becomes insoluble. When raw sugar contains much acid, and a strong grain is required, take one ounce of lime in powder for every four ounces of sulphate of zinc, and as much water as will form a milk of lime, which is added to the solution of sugar in the pan, about five minutes after the solution of sulphate of zinc has been added. This purification of sugar by separating impurities chemically combined with it, is employed with much advantage in conjunction with the patent filtering apparatus invented by Mr. John Sutherland. The solution of sugar brought to the boiling point is run through the filter, and afterwards boiled to a proof. Mr. Wilson boils the syrup in a pan, having a coil of tinned copper or pure tin tubes placed along its bottom and sides, through which a constant stream of strongly heated oil, or rather fatty matter, is made to pass. The oxide of zinc, precipitated previously by adding a solution of the salt to lime-water, is also recommended, as well as the oxide of tin.

Mr. Kirchoff, an ingenious Russian chemist, accidentally discovered that starch is convertible into sugar, by being boiled for some time with a very dilute sulphuric acid. Saussure showed that 100 parts of starch yield 110 of sugar. He concluded that this sugar was merely a compound of water and starch. According to his analysis starch consists of

Oxygen	56.87
Carbon	37.29
Hydrogen	6.84
	<hr/>
	100.00

Sugar of grapes, according to the same chemist, is composed of,

Oxygen	56.51
Carbon	36.71
Hydrogen	6.78
	<hr/>
	100.00

Common sugar has been analysed by many eminent chemists. The following is a general view of the results:—

	G. Lussac and Thenard.	Berzelius, Mean of 3.	Prout.
Oxygen	50.63	49.856	53.35
Carbon	42.47	43.265	39.99
Hydrogen	6.90	6.879	6.66
	<hr/>	<hr/>	<hr/>
	100.00	100.000	100.00

By my ultimate analysis of sugar its constituents are,

Carbon	43.38	5 atoms	45.4
Hydrogen	6.29	4 . . .	6.1
Oxygen	50.33	4 . . .	48.5
	<hr/>		<hr/>
	100.00		100.0

Phil. Trans. 1822.

It may be observed that Dr. Prout's experimental results agree with M. Gay Lussac's theory, of sugar being a compound of 40 parts of carbon + 60 of water, or its elements. By Berzelius's analysis starch consists of,

Oxygen	49.5
Carbon	43.5
Hydrogen	7.0
	100.0

The abstraction of a little hydrogen and carbon would convert it into sugar. But no carbonic acid or other gas is extricated during the conversion, according to Vogel's experiments. I find that potatoes digested with dilute sulphuric acid yield sugar cheaply and abundantly. The acid is afterwards removed by chalk; and the strained liquor left to repose, after due evaporation, affords crystals of sugar. From starch sugar, good beer has been made. I would recommend potatoes for this purpose. They are washed, grated down, and treated with the dilute acid for a day or two at a temperature of 212°.

M. Braconnot has recently extended our views concerning the artificial production of sugar and gum. Sulphuric acid (specific gravity 1.827) mixed with well dried elm dust, became very hot, and on being diluted with water, and neutralised with chalk, afforded a liquor which became gummy on evaporation. Shreds of linen triturated in a glass mortar with sulphuric acid yield a similar gum. Nitric acid has a similar power. If the gummy matter from linen be boiled for some time, with dilute sulphuric acid, we obtain a crystallisable sugar, and an acid, which M. Braconnot calls the vegeto-sulphuric acid. The conversion of wood also into sugar will no doubt appear remarkable; and, when persons not familiarised with chemical speculations are told that a pound weight of rags can be converted into more than a pound weight of sugar, they may regard the statement as a piece of pleasantries, though nothing, says M. Braconnot, can be more real.

Silk is also convertible into gum by sulphuric acid. Twelve grammes of glue, reduced to powder, were digested with a double weight of concentrated sulphuric acid without artificial heat. In twenty hours the liquid was not more colored than if mere water had been employed. A decilitre of water was then added, and the whole was boiled for five hours, with renewal of the water, from time to time, as it wasted. It was next diluted, saturated with chalk, filtered, and evaporated to a syrupy consistence, and left in repose for a month. In this period a number of granular crystals had separated, which adhered pretty strongly to the bottom of the vessel, and had a very decided saccharine taste. This sugar crystallises much more easily than cane sugar. The crystals are gritty under the teeth, like sugar-candy, and in the form of flattened prisms or tabular groups. Its taste is nearly as saccharine as grape sugar; its solubility in water scarcely exceeds that of sugar of milk. Boiling alcohol, even when diluted, has no action on this sugar. By distillation it yields ammonia, indicating the presence of azote. This sugar combines intimately with nitric acid without sensibly decomposing it, even with the assistance of heat, and there results a peculiar crystallised acid, to which the name nitro-saccharine has been given.—*Annales de Chimie*, xii., or *Tilloch's Magazine*, vol. 55 and 56.

The varieties of sugar are, cane sugar, maple sugar, liquid sugar of fruits, sugar of figs, sugar of grapes, starch sugar, the mushroom sugar of Braconnot, manna, sugar of gelatin, sugar of honey, and sugar of diabetes.

Sugar of grapes does not affect a peculiar form. It is deposited from its alcoholic solution in small grains, which have little consistence, are grouped together, and which constitute tubercles similar to those of cauliflowers. When put in the mouth it produces at first a sensation of coolness, to which succeeds a saccharine taste not very strong. Hence, to sweeten to an equal degree the same quantity of water, we must employ two and a half times as much sugar of grapes as of that of the cane. In other respects it possesses all the properties of cane sugar. Its extraction is very easy. The expressed juice of the grapes is composed of water, sugar, mucilage, bitartrate of potash, tartrate of lime, and a small quantity of other saline matters. We pour into it an excess of chalk in powder, or rather of pounded marble. There results, especially on agitation, an effervescence, due to the unsaturated tartaric acid. The liquor is then clarified with whites of eggs or blood. It is next evaporated in copper pans till it marks a density of 1.32 at the boiling temperature. It is now allowed to cool. At the end of some days it concretes into a crystalline mass, which, when drained, washed with a little cold water, and strongly compressed, constitutes sugar. In the south of France, where this operation was some years back carried on on the great scale, to prevent fermentation of the *must*, there was added to this a little sulphate of lime, or it was placed in tuns in which sulphur matches had been previously made to burn. The oxygen of the small quantity of air left in the tuns being thus abstracted by the sulphurous acid, fermentation did not take place. By this means the *must* can be preserved a considerable time; whereas, in the ordinary way, it would lose its saccharine taste at the end of a few days and become vinous. *Must* thus treated is said to be muted. The syrup was evaporated to the density of only 1.285.—Proust, *Ann. de Chimie*, lvii. 131; and the *Collection of Memoirs* published by Parmentier in 1813.

It is this species of sugar which is obtained from starch and woody fibre by the action of dilute sulphuric acid.

Sugar of diabetes has sometimes the sweetening force of sugar of grapes: occasionally much less.

Braconnot's mushroom sugar is much less sweet than that of the cane. It crystallises with remarkable facility, forming long quadrilateral prisms with square bases. It yields alcohol by fermentation.

All honeys contain two species of sugar: one similar to sugar of the grape, another like the uncrystallisable sugar of the cane (melasses). These combined, and mingled in different proportions with an odorant matter, constitute the honeys of good quality. Those of inferior quality contain, besides, a certain quantity of wax and acid: the honeys of Brittany contain even an animal secretion (*convain*) to which they owe their putrescent quality. A slight washing with

a little alcohol separates the uncrystallisable sugar, and leaves the other, which may be purified by washing with a very little alcohol.

'The relation,' says Dr. Prout, 'which exists between urea and sugar seems to explain in a satisfactory manner the phenomena of diabetes, which may be considered as a depraved secretion of sugar. The weight of the atom of sugar

is just half that of the weight of the atom of urea; the absolute quantity of hydrogen in a given weight of both is equal; while the absolute quantities of carbon and oxygen in a given weight of sugar are precisely twice those of urea.'

The constituents of these two bodies and lithic acid are thus expressed by that ingenious philosopher:—

ELEMENTS.	UREA.			SUGAR.			LITHIC ACID.		
	No.	Per Atom.	Per Cent.	No.	Per Atom.	Per Cent.	No.	Per Atom.	Per Cent.
Hydrogen	2	2.5	6.66	1	1.25	6.66	1	1.25	2.85
Carbon	1	7.5	19.99	1	7.50	39.99	2	15.00	34.28
Oxygen	1	10.0	26.66	1	10.00	53.33	1	10.00	22.85
Azote	1	17.5	46.66				1	17.50	40.00
	5	37.5	100.00	3	18.75	100.00	5	43.75	100.00

The above compounds appear to be formed by the union of more simple compounds, as sugar, of carbon and water; urea, of carburetted hydrogen and nitrous oxide; lithic acid, of cyanogen and water, &c., whence it is inferred that their artificial formation falls within the limits of chemical operations.

SUGAR, ACID OF. See ACID, CHEMISTRY, and OXALIC ACID.

SUGAR CANDY is the true essence of the cane formed into large crystals by a slow process. When the syrup is well clarified it is boiled a little, but not so much as is done for the proof mentioned in the process for making common sugar. It is then placed in old moulds, having their lower ends stopped with linen, and crossed at little distances with small twigs to retain the sugar as it crystallises. The moulds are then laid in a cool place. In proportion as the syrup cools, crystals are formed. In about nine or ten days the moulds are carried to the stove and placed in a pot; but the linen is not removed entirely, so that the syrup falls down slowly in drops. When the syrup has dropped away, and the crystals of the sugar-candy are become dry, the moulds are taken from the stove and broken in pieces to disengage the sugar, which adheres strongly to the sides of the moulds. If the syrup has been colored with cochineal the crystals take a slight tint of red; if indigo has been mixed they assume a bluish color. If it be desired to have the candy perfumed, the essence of flowers or amber may be dropped into the moulds along with the syrup.

SUGAR CANE, in botany. See SACCHARUM and SUGAR.

The SUGAR MAPLE, *acer saccharinum* of Linnaeus (see ACER), as well as the sugar-cane, produces a great quantity of sugar. This tree grows in great numbers in the western counties of all the middle states of the American union. Those which grow in New York and Pennsylvania yield the sugar in a greater quantity than those which grow on the waters of Ohio. These trees are generally found mixed with the beech, hemlock, white and water ash, the cucumber

tree, linden, aspen, butter nut, and wild cherry trees. They sometimes appear in groves covering five or six acres in a body, but they are more commonly interspersed with some or all of the forest trees which have been mentioned.

From thirty to fifty trees are generally found upon an acre of ground. They grow only in the richest soils, and frequently in stony ground. Springs of the purest water abound in their neighbourhood. They are, when fully grown, as tall as the white and black oaks, and from two to three feet in diameter. They put forth a beautiful white blossom in spring before they show a single leaf. The color of the blossom distinguishes them from the *acer rubrum* (see ACER), or the common maple, which affords a blossom of a red color. The wood of the sugar maple-tree is extremely inflammable, and is preferred upon that account by hunters and surveyors for fire-wood. Its small branches are so much impregnated with sugar as to afford support to the cattle, horses, and sheep of the first settlers during the winter, before they are able to cultivate forage for that purpose. Its ashes afford a great quantity of potash, exceeded by few, or perhaps by none, of the trees that grow in the woods of the United States. The tree is supposed to arrive at its full growth in the woods in twenty years. It is not injured by tapping; on the contrary, the oftener it is tapped the more syrup is obtained from it. In this respect it follows a law of animal secretion. A single tree had not only survived but flourished after forty-two tapplings in the same number of years. The effects of a yearly discharge of sap from the tree, in improving and increasing the sap, are demonstrated from the superior excellence of those trees which have been perforated in a hundred places by a small wood-pecker which feeds upon the sap. The trees, after having been wounded in this way, distil the remains of their juice on the ground, and afterwards acquire a black color. The sap of these trees is much sweeter to the taste than that which is obtained from trees which have not been previously wounded, and it affords more sugar. From twenty-three gar-

ions and one quart of sap, procured in twenty-four hours from only two of those dark colored trees. Arthur Noble, esq., of the state of New York, obtained four pounds and thirteen ounces of good grained sugar. A tree of an ordinary size yields in a good season from twenty to thirty gallons of sap, from which are made from five to six pounds of sugar. Samuel Lowe, esq., a justice of peace in Montgomery county, in the state of New York, informed Arthur Noble, esq., that he had made twenty pounds and one ounce of sugar between the 14th and 23d of April, in 1789, from a single tree that had been tapped for several successive years before; and that he had once obtained twenty-three gallons in one day from a single tree. But such instances are uncommon. From the influence which culture has upon forest and other trees it has been supposed that, by transplanting the sugar maple-tree into a garden, or by destroying such other trees as shelter it from the rays of the sun, the quantity of the sap might be increased, and its quality much improved. A farmer in Northampton county, in Pennsylvania, planted a number of these trees above thirty years ago in his meadow, from three gallons of the sap of which he obtained every year a pound of sugar. The sap distils from the wood of the tree. Trees which have been cut down in winter, for the support of the domestic animals of the new settlers, yield a considerable quantity of sap as soon as their trunks and limbs feel the rays of the sun in the spring. It is in consequence of the sap of these trees being equally diffused through every part of them that they live three years after they are girded, that is, after a circular incision is made through the bark into the substance of the tree for the purpose of destroying it. It is remarkable that grass thrives better under this tree in a meadow than in situations exposed to the constant action of the sun. The season for tapping the trees is in February, March, and April, according to the weather which occurs. Warm days and frosty nights are most favorable to a plentiful discharge of sap. The quantity obtained in a day from a tree is from five gallons to a pint, according to the greater or less heat of the air. There is always a suspension of the discharge of sap in the night if a frost succeed a warm day. The perforation in the tree is made with an axe or an augur. The latter is preferred from experience of its advantages. The augur is introduced about three quarters of an inch, and in an ascending direction (that the sap may not be frozen in a slow current in the mornings or evenings), and is afterwards deepened gradually to the extent of two inches. A spout is introduced about half an inch into the hole made by this augur, and projects from three to twelve inches from the tree. The spout is generally made of the sumach or elder, which usually grows near the sugar trees. The tree is first tapped on the south side; when the discharge of its sap begins to lessen, an opening is made on the north side, from which an increased discharge takes place. The sap flows from four to six weeks, according to the temperature of the weather. Troughs large enough to contain three or four gallons made of white pine, or white ash, or of

dried water ash, aspen, linden, poplar, or common maple, are placed under the spout to receive the sap, which is carried every day to a large receiver, made of either of the trees before mentioned. From this receiver it is conveyed, after being strained, to the boiler. There are three modes of reducing the sap to sugar; by evaporation, by freezing, and by boiling; of which the latter is most general, as being the most expeditious. The profit of the maple tree is not confined to its sugar. It affords most agreeable melasses, and an excellent vinegar. The sap which is suitable for these purposes is obtained after the sap which affords the sugar has ceased to flow, so that the manufactories of these different products of the maple tree, by succeeding, do not interfere with each other. The melasses may be made to compose the basis of a pleasant summer beer. The sap of the maple is also capable of affording a spirit.

Dr. Rush, in the Transactions of the American Philosophical Society, vol. iii., has given an account, at length, of the sugar maple tree, of which the following is a short abstract:—The acer saccharinum of Linnæus, or sugar maple tree, grows in great quantities in the western counties of all the middle States of the American Union. It is as tall as the oak, and from two to three feet in diameter; puts forth a white blossom in the spring, before any appearance of leaves; its small branches afford sustenance for cattle, and its ashes afford a large quantity of excellent potash. Twenty years are required for it to attain its full growth. Tapping does not injure it, but on the contrary, it affords more syrup, and of a better quality the oftener it is tapped. A single tree has not only survived, but flourished after tapping, for forty years. Five or six pounds of sugar are usually afforded by the sap of one tree; though there are instances of the quantity exceeding twenty pounds. The sugar is separated from the sap either by freezing, by spontaneous evaporation, or by boiling. The latter method is the most used.

Dr. Rush describes the process; which is simple, and practised without any difficulty by the farmers. From frequent trials of this sugar, it does not appear to be in any respect inferior to that of the West Indies. It is prepared at a time of the year when neither insect, nor the pollen of plants, exists to vitiate it, as is the case with common sugar. From calculations grounded on facts, it is ascertained that America is now capable of producing a surplus of one-eighth more than its own consumption; that is, on the whole, about 135,000,000 lbs.; which, in the country, may be valued at fifteen pounds weight for one dollar. The Indians likewise extract sugar from the pith of the bamboo. The beet has lately been much cultivated in Germany for the purpose of extracting sugar from its root. For this the roots are taken up in autumn, washed clean, wiped, sliced lengthwise, strung on threads, and hung up to dry. From these the sugar is extracted by maceration in a small quantity of water; drawing off this upon fresh roots, and adding fresh water to the first roots, which is again to be employed in the same way, so as to get out all their sugar, and saturate

the water as much as possible with it. This water is to be strained and boiled down for the sugar. Some merely express the juice from the fresh roots, and boil this down; others boil the roots; but the sugar extracted in either of these ways is not equal in quality to the first.

Professor Lampadius obtained from 110 lbs. of the roots four pounds of well-grained white powder sugar; and the residuums afforded seven pints of a spirit resembling rum. Achard says that about a ton of roots produced him 100 lbs. of raw sugar, which gave fifty-five pounds of refined sugar, and twenty-five pounds of treacle. But the sugar which is so universally used is afforded by the sugar-cane (*arundo saccharifera*) which is raised in our colonies. When this plant is ripe it is cut down, and crushed by passing it between iron cylinders placed perpendicularly and moved by water or animal strength. The juice which flows out by this strong pressure is received in a shallow trough placed beneath the cylinder. The juice is called in the French sugar colonies *vesou*; and the cane, after having undergone this pressure, is called *bagasse*. The juice is more or less saccharine, according to the nature of the soil on which the cane has grown, and the weather that has predominated during its growth. It is aqueous, when the soil or the weather has been humid; and in contrary circumstances it is thick and glutinous.

The juice of the cane is conveyed into boilers, where it is boiled with wood ashes and lime. It is subjected to the same operation in three several boilers, care being taken to remove the scum as it rises. In this state it is called *syrup*; and is again boiled with lime and alum till it is sufficiently concentrated, when it is poured into a vessel called the cooler. In this vessel it is agitated with wooden stirrers, which break the crust as it forms on the surface. It is afterward poured into casks, to accelerate its cooling; and while it is still warm, it is conveyed into barrels standing upright over a cistern, and pierced through their bottom with several holes stopped with cane. The syrup which is not condensed filters through these canes into the cistern beneath; and leaves the sugar in the state called coarse sugar, or muscovado. This sugar is yellow and fat, and is purified in the islands in the following manner:—The syrup is boiled, and poured into conical earthen vessels, having a small perforation at the apex, which is kept closed. Each cone, reversed on its apex, is supported in another earthen vessel. The syrup is stirred together, and then left to crystallise. At the end of fifteen or sixteen hours, the hole in the point of each cone, is opened, that the impure syrup may run out. The base of these sugar-loaves is then taken out, and white pulverised sugar substituted in its stead, which being well pressed down, the whole is covered with clay, moistened with water. This water filters through the mass, carrying the syrup with it which was mixed with the sugar, but which by this management flows into a pot substituted in the place of the first. This second fluid is called fine syrup. Care is taken to moisten and keep the clay in a proper degree of softness as it becomes dry. The sugar loaves are afterward taken out and

dried in a stove for eight or ten days; after which they are pulverised, packed, and exported to Europe, where they are still farther purified.

SUGAT, a town of Asia Minor, in the patriarchal of Bursa, occupying the site of the ancient Tottarium. The houses are built of wood and mud, in general two stories high, with projecting verandahs, and roofed with a red tile, which almost always admits the rain. It is remarkable for the tomb of Ali Osman.

SUGER (abbé), a French priest and prime minister of France, who flourished in the eleventh century, and died in 1152. His reputation was so great that after his death it was thought sufficient to inscribe on his tomb, *Cy git l'abbé Sugar*. Here lies the abbé Sugar. Of consequence we know no more of him. David Hume was influenced by a similar piece of vanity when he ordered his name, and no more, to be inscribed on his monument.

SUGGEST, *v. a.* } Fr. *suggérer*; Lat. *sug-*
SUGGESTER, *n. s.* } *gero, suggestum*. To hint;
SUGGESTION. } intimate; insinuate good
or ill; inform secretly; seduce (these last two are obsolete): the noun substantives corresponding.
It allayeth all base and earthly cogitations, banisheth and driveth away those evil secret suggestions which our invisible enemy is always apt to minister.
Hooker.

He was a man
Of an unbowed stomach, ever ranking
Himself with princes; one that by suggestion
Tied all the kingdom. *Shakspeare. Henry VIII.*

When devils will their blackest sins put on,
They do suggest at first with heavenly shows.
Shakspeare.

Arthur, they say, is killed to-night
On your suggestion. *Id. King John.*

Are you not ashamed?
What spirit suggests this imagination? *Shakspeare.*
Some ideas make themselves way, and are suggested to the mind by all the ways of sensation and reflexion.
Locke.

Native and untaught suggestions of inquisitive children.
Id.

These Romish casuists speak peace to the consciences of men, by suggesting something to them which shall satisfy their minds, notwithstanding a known, actual, avowed continuance of their sins.
South.

Search for some thoughts thy own suggesting mind,
And others dictated by heavenly power
Shall rise spontaneous. *Pope's Odyssey.*

SUG'GILATE, *v. a.* Lat. *suggillo*. To beat black and blue; to make livid by a bruise.

The head of the os humeri was bruised, and remained suggilated long after. *Wiseman's Surgery.*

SUGULMESSA, SIGILMESSA, or, according to Jackson, SEGIL MESSA, a district of Africa to the south-west of Morocco, beyond the Atlas. It forms part of that immense plain which intervenes between Barbary and the Great Sahara. Aridity is the prevailing character of the soil, though it still retains moisture sufficient for the production of dates. At an early period Sugulmessa was a city of importance, being the rendezvous of the caravans from Morocco to Soudan; but since these have been in the habit of passing by Akka and Jaffa, Sugulmessa has lost its importance; the district is now included in the kingdom of Tafilet.

SUHLA, a town of Prussian Saxony, the chief place of the circle of the Henneberg, is situated in the hilly track called the Forest of Thuringia. It contains four churches, four hospitals, and two manufactures of a very different description, viz. fire-arms and cotton goods, particularly dimity. From the fifteenth to the seventeenth century this was the principal place in Germany for fire-arms. At present this manufacture, though shared with a number of other towns, is still sufficient to consume the metals prepared at six forges. The cotton manufactures were introduced in the latter part of the eighteenth century. Inhabitants 6000. Eight miles north by west of Schleussingen.

SUHM (Peter Frederick), a celebrated Danish historian, was born at Copenhagen October 18th, 1728, and descended from a family originally from Germany, but long settled in Denmark. He displayed in his youth an unconquerable passion for reading; and in 1746 he was admitted into the university of Copenhagen, where the ensuing year he received the title of hof-junker, or gentleman of the court. He was after appointed assessor of the court tribunal; but having accepted of this office merely to gratify his father, an admiral in the Danish service, he ere long resigned it. Though the government successively made him gentleman of the royal chamber, counsellor of conference, chamberlain, and at last historiographer royal, he scarcely ever interfered in public affairs; the only occasion on which he is known to have done so having been at the revolution, which proved fatal to Struensee, when he joined the party of the queen-dowager, and drew up the plan of a temperate monarchical constitution, which, however, was not adopted. Suhm, who was a member of almost all the literary academies in the north of Europe, died of the gout on the 7th of September, 1798. His principal writings are An Introduction to the Critical History of Denmark, 1769—73, 5 vols. 4to; The Critical History of Denmark during the Pagan Ages, 1774—81, 4 vols.; The Modern History of Denmark, of which seven volumes have been published, the first of which appeared in 1782. His miscellaneous works were collected and reprinted, with an account of his life, at Copenhagen 1788—98, 15 vols.

SUICIDE, *n. s.* Lat. *suicidium*. Self-murder; the crime of destroying one's self: a self-murderer.

Child of despair, and *suicide* my name. *Savage*.
To be cut off by the sword of injured friendship is the most dreadful of all deaths, next to *suicide*.

Clarissa.

If fate forbears us, fancy strikes the blow;
We make misfortunes, *suicides* in woe. *Young*.

SUICIDE is one of those crimes which are not common among savage nations. The first instances of it recorded in the Jewish history are those of Saul and Ahithophel; for the death of Samson is not a proper example. It never became common among the Jews till their wars with the Romans, when multitudes slaughtered themselves that they might not fall alive into the hands of their enemies. But at this period the Jews were a most desperate and abandoned race of men, had corrupted the religion of their fathers,

and rejected that pure system which their promised Messiah came to Jerusalem to announce. We know not when it became remarkable among the Greeks; but it was forbidden by Pythagoras, by Socrates and Aristotle, and by the Theban and Athenian laws. In the earliest ages of the Roman republic it was seldom committed; though that republic owed its origin to the suicide of Lucretia: but, when luxury and the Epicurean and Stoical philosophy had corrupted the simplicity and virtue of the Roman character, then they began to seek shelter in suicide from their misfortunes or the effects of their vices. The religious principles of the Brahmins of India led them to admire suicide on particular occasions as honorable. Accustomed to abstinence, mortification, and the contempt of death, they considered it as a mark of weakness of mind to submit to the infirmities of old age. The modern Gentoos, who still in most things conform to the customs of their ancestors, when old and infirm, are frequently brought to the banks of rivers, particularly to those of the Ganges, that they may die in its sacred streams, which they believe can wash away the guilt of their sins. But the maxims of the Brahmins, which have encouraged this practice, we are assured by Mr. Holwell, are a corruption of the doctrines of the Shasta, which positively forbid suicide. The practice which religion or affection has established among the Gentoos, for women at the death of their husbands to burn themselves alive on the funeral pile (See HINDOOS), we do not think ought to be considered as suicide; for, were we to extend it thus far, it would be as proper to apply it to those who choose rather to die in battle than escape at the expense of their honor; and we should condemn as suicides the brave Spartans, who died at Thermopylæ in the defence of their country: we should also be obliged to apply the same disgraceful epithet to all those well-meaning but weak-minded Christians in this island, who in the seventeenth century chose rather to die as martyrs than comply with commands which they thought unlawful, though they were not morally wrong.

According to the historians of Japan, voluntary death is common in that empire. The devotees of the idol Amida drown themselves in his presence, attended by their relations and friends, and several of the priests, who all consider the devoted person as a saint who is gone to everlasting happiness. Such being the supposed honors appropriated to a voluntary death, it is not surprising that the Japanese anxiously cherish a contempt of life. Accordingly suicide is held as the most heroic of actions. A notion also prevailed among the ancient Scythian tribes, that it was pusillanimous for a man whose strength was wasted with disease or infirmity, to continue to live. It was reckoned an heroic action voluntarily to seek that death which he had the good fortune to meet in battle. The tribes of Scandinavia, who worshipped Odin the 'father of slaughter,' were taught that dying in the field of battle was the most glorious event that could befall them. See MYTHOLOGY, ODIN, and VALHALLA. This was a maxim suited to a warlike nation. Natural death being thus deemed inglorious

rious, and punished with exclusion from Valhalla, the paradise of Odin, he who did not fall in battle was led to suicide, when sickness or old age began to assail him. In such a nation suicide must have been very common. As suicide prevailed much in the decline of the Roman empire, when luxury, licentiousness, profligacy, and false philosophy, pervaded the world, so it continued to prevail even after Christianity was established. But the principles from which it proceeded were explained, so as to appear more agreeable to the new system which they had espoused. It was committed, either to secure from the danger of apostasy, to procure the honor of martyrdom, or to preserve the crown of virginity. In modern times we lament to find so many instances of suicide among the most polished nations who have the best opportunities of knowing the atrocity of that unnatural crime. The English have long been reproached by foreigners for the frequent commission of it; and the 'gloomy month of November' has been stigmatized as the season when it is most common. But this imputation may be justly attributed, not to the greater frequency of the crime in England than in other places, but to the custom of publishing in the newspapers every instance of suicide which is known. Mr. Moore was at great pains to obtain accurate information concerning the perpetration of this crime in different countries. Mercier, who wrote in 1782, says that the annual number of suicides in Paris was then about 150. But the abbé Fontana asserts that more persons put an end to their lives in Paris than in London. He had this information from the lieutenant of police. Mr. Moore was informed by a magistrate of Geneva that in that city, which contains about 25,000 inhabitants, the average number of suicides is about eight. In twenty-eight years there were thirty-two each year for London, Southwark, and Westminster at the same period, and in Edinburgh, containing above 80,000 inhabitants, the average number of suicides did not exceed four. Mr. Moore was informed by the coroners of Kent that for the last eighteen years the number had been upwards of thirty-two each year. Kent then containing about 200,000 inhabitants, and London 800,000. In the metropolis, therefore, many instances of suicide occur which are never known to the world; whereas in the country towns and villages it is scarcely possible to conceal such an action. The calculation therefore respecting Kent we may receive as true, while we must increase the average number in London very considerably. Mercier says that at Paris the lower ranks were most commonly guilty of it; that it was committed in garrets or hired lodgings; and that it proceeded from poverty and oppression. Many, he says, wrote letters to the magistrates before their death. Mr. Moore's correspondent from Geneva informed him that from 1777 to 1787 more than 100 suicides were committed in Geneva; that two-thirds of these unfortunate persons were men; that few of the clerical order have been known to commit it; and that it is not so much the end of an immoral, irreligious, dissipated life, as the effect of melancholy and poverty. By the information obtained from the coroners of Kent,

it appears that, of the thirty-two, three-fourths destroyed themselves by hanging; that the proportion of males to females has been about two-thirds of the former; that no one season of the year is more distinguished for this crime than another; and that suicide was upon the increase. Our accounts respecting London are very imperfect; but we think that suicide is more common among the great and wealthy than among the lower ranks, and that it is usually the effect of gaming and dissipation.

As suicide was deemed a crime by the most illustrious of the Greek and Roman philosophers, it was considered as a crime by the laws, and treated with ignominy. By the law of Thebes suicides were to have no honors paid to their memory. The Athenian law ordained the hand which committed the deed to be cut off, and burned apart from the rest of the body. The body was not buried with the usual solemnities, but was ignominiously thrown into some pit. In Cea and Massilia (the ancient Marseilles) it was considered as a crime against the state. Plutarch relates, that an unaccountable passion for suicide seized the Milesian virgins; from which they could not be prevented by the tears and entreaties of friends: but a decree being issued, 'that the body of every young woman who hanged herself should be dragged naked through the streets, by the same rope with which she had committed the deed,' a complete stop was put to the extraordinary frenzy. In the early part of the Roman history the only instance recorded occurs in the reign of Tarquin I. The soldiers who were appointed to make common sewers, thinking themselves disgraced by such offices, put themselves to death in great numbers. The king ordered the bodies of all the self-murderers to be exposed on crosses, and this put a stop to the practice. There was no law against suicide during the republic; but under the emperors it was thought proper to lay it under certain regulations. When the Christian church had extended its jurisdiction in the Roman empire it was decreed, in the sixth century, that no commemoration should be made in the eucharist for such as destroyed themselves; neither should their bodies be carried out to burial with psalms, nor have the usual service said over them. This ecclesiastical law continued till the reformation, when it was admitted into the statute code of England by the authority of parliament. As an additional punishment, however, confiscation of land and goods seems to have been adopted from the Danes. At present the punishment consists in confiscating all the personal property of a felon for the use of the crown, and in excluding his body from interment in consecrated ground. Formerly the warrant of the coroner required that the body should be buried in some public highway, and a stake driven through it; but this has been recently abolished. Suicide is a common evil, but it is difficult to find an effectual remedy; for what motives can be held out sufficient to influence that man's mind who is dead to the voice of nature, and nature's God? His reputation and property are indeed within the reach of the laws, his body may be treated with ignominy, and his property con-

fiscated; but this punishment will not be a preventive even if it could be always inflicted; and that it is seldom inflicted is well known. Humanity disposes us to sympathise with the relations of the deceased, instead of demanding that the sentence of the law should be executed.

In countries, such as some of those above-mentioned, where suicide is recommended by false views of honor or of religion, there can be no preventive till a general change takes place in such customs and habits of thinking. But in the civilised countries of Europe, where no such false opinions prevail, much might be done, with proper care and attention, to prevent many of the accidents of this kind that daily happen. We call them accidents, and not crimes, because among the class we speak of, the deed is often involuntary, and therefore not criminal. For although there have doubtless been many who very unfortunately have been led to commit this crime from pride, habits of dissipation, and a total want of religious principle, yet of the great numbers whom we annually read of in the public newspapers, we may charitably hope that the majority are really in a state of insanity when they commit this rash action. Persons of either sex, who have met with great misfortunes, either by loss of property, or still more readily by the loss of near and dear relations, are apt, if allowed to indulge their grief, to grow low-spirited and melancholy, and gradually to fall into such a weak state of the nerves as at last to affect the brain. They either do not sleep, or their sleep is not sound or refreshing. Young women, by disappointments in love, and married women by the death of husbands or favorite children, often fall into such a degree of hysteria as to be nothing short of absolute lunacy. And it is acknowledged by physicians that the most amiable of the sex, and those of the best dispositions, are, from their excess of sensibility, most apt to fall into that habit of body and mind in consequence of the loss of near and dear relations. In such cases such persons should never be left a moment alone while under the influence of such a malady: and, though medicine can do little to recover patients in these cases, yet the most fatal effects may be prevented by a constant attention to them on the part of friends, and by their endeavours to console and solace them, by amusement, air, and exercise, and every species of kind usage. The writer of this article knew an instance of a lady in Edinburgh, who had lingered long in a desperate state of hysteria, who one night rose out of bed and ran to a window four stories high, which she opened, but was prevented from throwing herself over by her husband awaking and catching her in his arms just when she had nearly accomplished it. She thought she was in a prison, and that was the easiest way out. She was afterwards, by proper care, completely restored to her senses; but it is highly probable that, among the numerous suicides we daily hear of, there are many similar instances where no deliberate intention of self-murder is entertained.

In the whole train of nervous, hysterical, and hypochondriac affections, there is no symptom so decisive of the approach of an incipient lu-

nacy as the want of sleep, or what physicians call an altered state of sleep. It is often induced by a continued melancholy and brooding over past misfortunes; but it is also sometimes occasioned by excessive joy upon some sudden circumstance of great prosperity. The writer of this article knew a melancholy instance of this last effect. A gentleman possessed of a small fortune, by the death of a relation abroad fell heir to a large estate. The fourth day after the news had arrived the writer called and congratulated him on his good fortune; when, amidst much hospitality, and many promises of making all his friends the better for it, he mentioned that he had got no sleep since he received the letter. To this the writer replied that this was a dangerous state of health, and sleep must be procured by soporifics as quickly as possible, else the consequences might be fatal. Next time he called, which was only within a week, his unfortunate friend was in confinement under keepers; and within two months, so rapidly did his son seize the opportunity his father's misfortune afforded him, the old gentleman was cognosed as a lunatic, and the son legally put in possession of the whole fortune; thus fulfilling Ovid's remark,

Filius ante diem patrios inquit in annos!

SUIDAS, a Greek writer, who, according to some, flourished in the eleventh century under Alexius Comnenus; according to others in the tenth century. He wrote, in Greek, an Historical and Geographical Dictionary or Lexicon, a work which, though not always strictly accurate, is nevertheless of great importance, as it contains many things taken from the ancients nowhere else to be found. The best edition of Suidas is that of Kuister, in Greek and Latin, with notes, in three volumes folio, which has been much improved by Toup.

SUILLAGE, *n. s.* Fr. *souillage*. Drain of filth. Obsolete.

When they have chosen the plot, and laid out the limits of the work, some Italians dig wells and cisterns, and other conveyances for the *suillage* of the house. *Watson.*

SU'ING, *n. s.* From Fr. *suer*, to sweat, it is perhaps peculiar to Bacon. The act of soaking through any thing.

Note the percolation or *suing* of the verjuice through the wood: for verjuice of itself would never have passed through the wood. *Bacon.*

SUIONES, an ancient people of Germany, mentioned by Tacitus, supposed to have inhabited Sweden.

SUIT, *n. s., v. a., & v. n.* } Fr. *suite*. A set;
 SUITABLE, *adj.* } a number of things
 SUITABLY, *adv.* } correspondent one
 SUITER, or } to the other; a set
 SUIT'OR, *n. s.* } of clothes; series;
 SUIT'RESS. } a petition; an action
 at law; courtship; regular order: 'out of suits,' out of order or consecution: to suit is, to fit; adapt; be fitted to; become: as a verb neuter, to agree; accord: suitable is, fitting; according: the adverb and noun substantive corresponding: suiter or suitor, he, suitress, she who sues.

Many shall make *suit* unto thee. *Job xi. 19.*
All that had any *suits* in law came unto them.

Susanna.

Through all those miseries, in both there appeared a kind of nobleness not *suitable* to that affliction.

Sidney.

High amongst all knights hast hung thy shield,
Thenceforth the *suit* of earthly conquest shone,
And wash thy hands from guilt of bloody field.

Spenser.

As humility is in *suiters* a decent virtue, so the testification thereof, by such effectual acknowledgments, not only argueth a sound apprehension of his supereminent glory and majesty before whom we stand, but putteth also into his hands a kind of pledge or bond for security against our unthankfulness.

Hooker.

What he did purpose, it was the pleasure of God that Solomon his son should perform, in manner *suitable* to their present and ancient state. *Id.*

He that hath the steerage of my course,
Direct my *suit*. *Shakespeare. Romeo and Juliet.*

Wear this for me; one out of *suits* with fortune,
That would give more, but that her hand lacks means. *Shakespeare.*

Suit the action to the word, the word to the action, with this special observance, that you o'erstep not the modesty of nature. *Id. Hamlet.*

I would I could find in my heart that I had not a hard heart; for truly I love none.

—A dear happiness to women! they would else have been troubled with a pernicious *suitor*.

Shakespeare.

Be better *suitèd*;

These weeds are memories of those misfortunes:
I pry'thee put them off to worse hours. *Id.*

I'll disrobe me

Of these Italian weeds, and *suit* myself
As does a Briton peasant. *Id. Cymbeline.*

What a beard of the general's cut, and a horrid *suit* of the camp, will do among foaming bottles, and ale-washed wits, is wonderful. *Id. Henry V.*

She hath been a *suitor* to me for her brother,
Cut off by course of justice. *Id. Measure for Measure.*

Wars are *suits* of appeal to the tribunal of God's justice, where there are no superiors on earth to determine the cause. *Bacon's War with Spain.*

Not only bind thine own hands, but bind the hand of *suitors* also from offering. *Bacon.*

By many *suitors* sought, she mocks their pains,
And still her vowed virginity maintains. *Dryden.*

This says, because it *suits* with his hypothesis, but proves it not. *Locke.*

Whosoever speaks upon an occasion may take any text *suitable* thereto; and ought to speak *suitably* to that text. *South.*

He creates those sympathies and *suitablenesses* of nature that are the foundation of all true friendship, and by his providence brings persons so affected together. *Id.*

Give me not an office

That *suits* with me so ill; thou knowest my temper. *Addison.*

'Twere pity

That could refuse a boon to such a *suitress*;
Y' have got a noble friend to be your advocate. *Rowe.*

My lord, I come an humble *suitor* to you. *Id.*

It will be as unreasonable to expect that God should attend and grant those *suits* of ours, which we do not at all consider ourselves. *Duty of Man.*

John Bull was flattered by the lawyers that his *suit* would not last above a year, and that before that

time he would be in quiet possession of his business. *Arbutnot.*

As the blessings of God upon his honest industry had been great, so he was not without intentions of making *suitable* returns in acts of charity. *Atterbury.*

He drew his seat, familiar, to her side,
Far from the *suitor* train, a brutal crowd. *Pope's Odyssey.*

It is as great an absurdity to suppose holy prayers and divine petitions without an holiness of life *suitable* to them, as to suppose an holy and divine life without prayers. *Law.*

SUIT is used in different senses; as, 1. *Suit* custom, which is where one and his ancestors have owed *suit* time out of mind. 2. It is used for a petition to the king or any person of dignity, where a lord distrains his tenant for *suit* and none is due. In this case the party may have an attachment against him to appear in the king's court.

SUIT, in law, is the same as action. The Romans introduced pretty early set forms for actions and *suits* into their law, after the example of the Greeks; and made it a rule that each injury should be redressed by its proper remedy only. See *ACTIO* and *ACTION*. The forms of these actions were originally preserved in the books of the pontifical college as choice and inestimable secrets, till one Cneius Flavius, the secretary of Appius Claudius, stole a copy and published them to the people. The concealment was ridiculous. Bracton, speaking of the original writs upon which all our actions are founded, declares them to be fixed and immutable, unless by authority of parliament. And all the modern legislators of Europe have found it expedient to fall into the same or a similar method. In England the several *suits* of justice are, from the subjects of them, distinguished into three kinds; actions personal, real, and mixed. 1. Personal actions are such whereby a man claims a debt, or personal duty, or damages in lieu thereof; and likewise whereby a man claims a satisfaction in damages for some injury done to his person or property. The former are said to be founded upon contracts, the latter upon torts or wrongs. Of the former nature are all actions upon debts or promises; of the latter are all actions of trespasses, nuisances, assaults, defamatory words, and the like. 2. Real actions (or feudal actions), which concern real property only, are such whereby the plaintiff, here called the demandant, claims title to have any lands or tenements, rents, commons, or any other hereditaments, in fee-simple, fee-tail, or for term of life. By these actions formerly all disputes concerning real estates were decided; but they are now pretty generally laid aside; a much more expeditious method of trying titles being introduced by actions personal and mixed. 3. Mixed actions are *suits* partaking of the mixture of the other two, wherein some real property is demanded, and also personal damages for a wrong sustained. As for instance an action of waste: which is brought by him who hath the inheritance, in remainder or reversion, against the tenant for life, who hath committed waste therein, to recover not only the land wasted, which would make it

a real action, but also treble damages, in pursuance of the statute of Gloucester, being a personal recompense; and so both, being joined together, denominate it a mixed action. See **LAW**.

SUITE, *n. s.* Fr. *suite*. Retinue; company. Plexirtus's ill-led life, and worse-gotten honour, should have tumbled together to destruction, had there not come in Tydeus and Telenor, with fifty in their *suite* to his defence. *Sidney*.

SULCATED, *adj.* Lat. *sulcus*. Furrowed. All are much chopped and *sulcated* by having lain exposed on the top of the clay to the weather, and to the erosion of the vitriolick matter mixed amongst the clay. *Woodward*.

SULL, a large valley of Greece, enclosed by almost inaccessible mountains. The only entrance, a defile on the south, is defended by three towers, nearly a mile distant from each other, and situated on eminences where the road is most difficult; the other three sides are composed of perpendicular precipices. This territory, about twenty-six miles long from north to south, and eight in breadth, is inhabited by a tribe of Greeks, who, until lately, maintained themselves in the form of an independent republic. It contains eighteen villages, of which five are situated in the southern and less difficult part of the valley towards Louro, and thirteen in the upper or more rugged and inaccessible part. The principal places are Mega Souli, the capital, Navarikes, and Kiapha. On the east, at the foot of the mountain, is a fine plain of about six square leagues. In it the Suliotes have settled for the purpose of cultivating the land, but in times of danger retire with their property to the mountains. On the south Suli is bounded by the Chimæra mountains. The population of this tribe is about 10,000. Their wars, particularly between 1786 and 1803, were remarkable for the courage and pertinacity which they displayed. In vain in 1792 did Ali Pacha attack them with a powerful army. He was repulsed as well in that year as subsequently; and it was not until 1803 that he definitely succeeded. On the loss of their independence, a part of the Suliotes left their country, and took service in Russia and France. Their country is at present again subject to the Porte.

SULIA, a large river of New Granada, in Pamplona. It rises in the vicinity of this province, runs north, and, collecting the waters of many other rivers, unites itself with the Catacumbo, and again separating itself, after a little space, it forms three mouths, whereby to enter the lake Maracaibo. Its mouth is in lat. 8° 35' N.

SULLEN, *adj.* } Saxon *sal*, *ryl*. The
SULLENLY, *adv.* } etymology is obscure;
SULLENNESS, *n. s.* } gloomily angry or discon-
SULLENS, *n. s.* } tented; intractable;
dark; heavy; dull: the adverb and noun substantive corresponding: the plural *sullens* is used burlesquely for morose temper; gloominess.

Speech being as rare as precious, her silence without *sullenness*, her modesty without affectation, and her shamefacedness without ignorance. *Sidney*.

Why are thine eyes fixt to the *sullen* earth,
Gazing at that which seems to dim thy sight?
Shakspeare. Henry VI.

Let them die that age and *sullens* have.
Shakspeare.

To fit my *sullenness*
He to another key his style doth dress. *Donne*.
Wilmot continued still *sullen* and perverse, and every day grew more insolent. *Clarendon*.

In those vernal seasons, when the air is calm and pleasant, it were an injury and *sullenness* against nature not to go out and see her riches. *Milton*.

Things are as *sullen* as we are, and will be what they are, whatever we think of them. *Tillotson*.

With these comforts about me, and *sullenness* enough to use no remedy, Zulichem came to see me. *Temple*.

A man in a jail is *sullen* and out of humour at his first coming in. *L'Estrange*.

A glimpse of moon-shine, streaked with red,
A shuffled, *sullen*, and uncertain light,
That dances through the clouds, and shuts again.
Dryden

He in chains demanded more
Than he imposed in victory before:
He *sullenly* replied, he could not make
These offers now. *Id. Indian Emperor*.

Forced by my pride, I my concern suppressed;
Pretended drowsiness, and wish of rest;
And *sullen* I forsook the imperfect feast. *Prior*.

No cheerful breeze this *sullen* region knows;
The dreaded east is all the wind that blows. *Pope*.

SULLIVAN, a county of New York, United States, bounded north-west by Delaware, north-east by Ulster, south by Orange, and south-west by the Delaware, which separates it from Pennsylvania. It contains a pretty large proportion of mountainous country, with fertile plains, however, intervening. Thompson is the chief town.

SULLIVAN COVE, a harbour about nine miles from the mouth of Derwent River, in Van Diemen's River, where a settlement was established in 1804.

SULLIVAN ISLAND, an island of the United States, at the mouth of Ashley and Cooper Rivers, six miles below Charleston, South Carolina; much resorted to by the people of Charleston during the summer months.

SULLIVAN MOUNTAINS, mountains of the United States, in New Hampshire, extending from Cockburne to the White Mountains; they are about 2000 feet high.

SULLY, *v. a. & n. s.* } Fr. *souiller*, *sulliage*.

SULLIAGE, *n. s.* } To soil; tarnish; dirt:
a tarnish or spot; pollution; filth. Neither of the noun substantives are in use.

You laying these light *sullies* on my son,
As 'twere a thing a little soiled 'i' the working.
Shakspeare.

Calumniate stoutly; for, though we wipe away with never so much care the dirt thrown on us, there will be left some *sulliage* behind.
Decay of Virtue.

The falling temples which the gods provoke,
And statues *sullied* yet with sacrilegious smoke.
Roscommon.

He's dead, whose love had *sullied* all your reign,
And made you empress of the world in vain.
Dryden.

A noble and triumphant merit breaks through little spots and *sullies* in his reputation.
Addison's Spectator.

Lab'ring years shall weep their destined race,
Charged with ill omens, *sullied* with disgrace.
Prior.

Ye walkers too, that youthful colours wear,
Three *sully*ng trades avoid with equal care;
The little chimney-sweeper skulks along,
And marks with sooty stains the heedless throng.

Gay.

Let there be no spots to *sully* the brightness of this solemnity.

Atterbury.

SULLY (Maximilian de Bethune, duke de), born at Rosny, December 13th, 1560, was of an ancient family, being the second son of Francis de Bethune and Charlotte D'Auuet. He was educated as a Protestant; and his father, possessing but a moderate fortune, presented him at the age of eleven to the queen of Navarre, who educated him with her son, afterwards Henry IV. Accompanying the latter to Paris, he narrowly escaped becoming a victim in the massacre of St. Bartholomew's day, and when the young king escaped from the court the baron du Rosny, as Sully was then called, retired with him. In the wars which Henry carried on before he obtained the crown, du Rosny greatly distinguished himself, particularly at Marinande, Lectoure, Coutras, where he commanded the artillery, and at Ivry, where he took the standard of the duke of Maine, and was dangerously wounded. In 1591 he took Gisors; and at Dreux in 1593, at Laon in 1594, at La Fere in 1596, at Amiens in 1597, and at Montmelian in 1600, reaped new laurels. His abilities as a diplomatist were no less remarkable. In 1586 he concluded a treaty with the Swiss for a supply of 20,000 troops; and in 1597 was placed at the head of the department of finance: about the same time he negotiated the marriage of Henry with Mary de Medici. After the death of our queen Elizabeth, he displayed great penetration and address in a treaty he concluded with James I., and was for some time ambassador at the English court. In addition to his other offices he was now appointed grand surveyor of France, grand master of the artillery, governor of the Bastille, and superintendent of fortifications. The revenues of the government, which had been reduced to a state of complete dilapidation by civil anarchy or open warfare, were by his care restored to order and affluence. He was no less firm than wise in his conduct. Whilst he was resisting applications for oppressive edicts, to which the king, who was always disposed to listen to the requests of his favorites and mistresses, inclined, his mistress d'Entragues, the marchioness de Verneuil, haughtily said to him, 'To whom would you have the king to grant favors, if not to his relations, courtiers, and mistresses?'—'Madam,' he replied, 'you would be in the right if his majesty took the money out of his own purse; but is it reasonable that he should take it from those of the traders, the artisans, the laborers, and peasants? These people, who maintain him and all of us, find one master sufficient, and have no need of so many courtiers, princes, and mistresses.' His industry was unwearied. Rising every morning at four o'clock, he dedicated a regular time to business, and then gave audience to all who solicited admission to him. Though he persevered in the reformed religion, he does not appear to have been very conscientiously

attached to it, as it was principally owing to his counsels that the king professed himself a Catholic. The pope, however, having addressed to him a letter, in which, after paying him many compliments, he invited him to become a Catholic, and concluded with declaring that he should always pray for his conversion; Sully, in his reply, observed that, on his part, he would never cease to pray God for the conversion of his holiness. In 1606 the territory of Sully-sur-Loire was erected into a duchy in his favor. After the murder of Henry IV. he was obliged to retire from court; but after some years he was recalled, and, on making his appearance in the royal circle, the courtiers did not treat him with that respect to which he thought himself entitled; on which he said to Louis XIII. 'Sire, when your father did me the honor to consult me, we never spoke on affairs till he had dismissed his flatterers and buffoons to the ante-chamber.' In 1634 he received the staff of a marshal in exchange for the office of grand master of the artillery; and died at Villebon, December 22d, 1641. His Memoirs were partly published by himself, under the title of *Economies Royales*, Amsterdam, 1634, 2 vols. folio, but printed in his own house; the third and fourth volumes were published at Paris in 1662.

SULMO, an ancient town of Italy, belonging to the Peligni, about ninety miles from Rome. founded by one of Æneas's followers. It is famous for having been the birth place of the poet Ovid; and is now called Sulmona.

SULMONA, an ancient town of Naples, in the Abruzzo Citra. It was the birth place of Ovid: in 1709 it was greatly injured by an earthquake. At present it contains 4000 inhabitants, and is the see of a bishop. Twenty-one miles south of Civita di Chieti, and seventy-two north of Naples.

SULPHATES, in chemistry, are definite compounds of sulphuric acid with the salifiable bases. See **SULPHURIC ACID**, and the respective bases.

SULPHITES is also a name for definite compounds of sulphuric acid with the bases.

SULPHUR, *ns. s.* } Lat. *sulphur*. Brim-
SULPHUREOUS, *adj.* } stone. See below. The
SULPHUROUS. } adjectives correspond.

My hour is almost come,
When I to *sulphurous* and tormenting flames
Must render up myself. *Shakspeare. Hamlet.*
Dart and javelin, stones and *sulphurous* fire. *Milton.*

In his womb was hid metallick ore,
The work of *sulphur*. *Id.*

Is not the strength and vigour of the action between light and *sulphureous* bodies, observed above, one reason why *sulphureous* bodies take fire more readily, and burn more vehemently, than other bodies do? *Newton's Opticks.*

Sulphur is produced by incorporating an oily or bituminous matter with the fossil salt. *Woodward.*

No *sulphureous* glooms
Swelled in the sky, and sent the lightning forth.

Thomson.

SULPHUR is a well known substance, yellow, hard, brittle, and when rubbed becomes electric. Its specific gravity is from 1.990 to 2.35. Ac-

cording to Bergman, it gently evaporates at 170°, melts at 185°, and flames at 302° of Fahrenheit. It burns with a blue flame, and a disagreeable suffocating smell; in close vessels it sublimes without decomposition, or only a decomposition proportionable to the quantity of air they contain; when melted it becomes red, but recovers its color on cooling. It is insoluble in water, though by long trituration water will take up some of it, but it is rather diffused than dissolved in it; neither can spirit of wine unite to it, except when both are in a vaporous state, and then seventy-two parts of spirit of wine take up one of sulphur; it is soluble in hot oils, and also in fixed alkalies, both in the dry and liquid way. See CHEMISTRY, Index. Sulphur, formerly considered as a compound, is now reckoned a simple substance, and is even ranked among the elements. This conclusion is founded on the following facts: 1. Sulphur does not burn unless oxygen have access to it. 2. During combustion it absorbs vital air from the atmosphere. 3. The sulphuric acid produced by the combustion of sulphur is equal in weight to the sulphur employed and the quantity of air that has been consumed.

Sulphur unites readily with most metallic substances, excepting gold, platinum, and zinc. The affinities of sulphur, according to Geoffroy, Bergman, and Dr. Thompson, are fixed alkalies, iron, copper, tin, lead, silver, bismuth, antimony, mercury, arsenic, and molybdenum. The compounds formed by sulphur with different metals are different; but all of them possess a metallic lustre, without any ductility: these combinations of sulphur and of metals are very frequently found in a natural state. Almost all the metals dug from the earth are found combined with sulphur, forming most of the ores and metallic minerals. It is a curious phenomenon, that nitre mixed with sulphur burns rapidly, even in close vessels; this is easily explained by the new system. Nitre, when heat is applied to it, yields a great quantity of oxygen gas; and sulphur has a strong attraction for oxygen. As oxygen is thus supplied, which is the only principle necessary to combustion, communication with the atmospheric air is unnecessary. The sulphur will burn till the whole oxygen which the nitre furnishes be consumed. The products obtained by this process are different according to the proportions of nitre and sulphur employed. If eight parts of sulphur and one of nitre be set on fire in a close vessel, sulphuric acid is produced; and this is the method by which oil of vitriol or strong sulphuric acid was formerly made in Great Britain. The vessels in which the operation was performed were large glass balloons, with very large necks, each containing 400 or 500 pints. But it was attended with great expense, on account of the high price and bitterness of the balloons. A few years ago a cheaper method was attempted with success in France. The sulphur is burned on a kind of gridirons, in large apartments lined with lead. As the acid condenses it is conveyed by gutters into a reservoir, and afterwards concentrated. The sulphuric acid thus obtained is always combined with a little sulphur and sulphate of pot-

ash, a small quantity of aluminous sulphate and sulphate of lead; but these substances are in so small a proportion, that for common use it is not necessary to separate them. If necessary, however, it may easily be done by distilling the acid to dryness. Gunpowder, the terrible effects of which are owing to its strong tendency to combustion, is a mixture of sulphur, nitre, and charcoal. See GUNPOWDER. But there is another mixture, of which sulphur is an ingredient, still more violent in its effects: this is called fulminating powder, and is composed of three parts of nitre, two parts of the carbonate of potash, and one of powdered sulphur. These being closely united together by trituration, in a hot marble mortar, when exposed to a slight degree of heat, will melt, and produce a violent detonation like the report of a cannon. A dram of this mixture is sufficient for the experiment. Sulphur is of great use in chemistry, in medicine, and the arts. Sulphur is useful in making some fusions, precipitations, and separations of metals and minerals: but is particularly useful, as being the substance from which the sulphuric acid is obtained.

Sulphur is employed in medicine both internally and externally. It is given either in flowers or in lozenges, made up with sugar, or joined to magnesia, crystals of tartar, manna, cassia, lenitive electuary, &c. Two or three drams generally prove laxative; and it is given in such doses in cases of piles, of uterine and other hæmorrhagies; because it does not stimulate nor heat during its operation, nor leave a disposition to costiveness, as rhubarb, aloes, and other hot residuous purges do. Sulphur was formerly much recommended in coughs and diseases of the breast, but of late its virtues as a pectoral have been much doubted. When applied externally, it is mixed with some unctuous substance, as hog's lard, butter, &c., and is rubbed on such parts of the body as are affected with eruptions. Some physicians and chemists, considering that sulphur is insoluble in water, and capable of resisting the action of most menstrua, have affirmed that it can produce no effect when taken internally, single and unaltered; but this assertion seems to be without foundation; for it is certain that the sweat and perspiration of those who take sulphur internally have a smell evidently sulphureous. Besides sulphur is much more soluble than is generally believed. It is attacked by all oily and saponaceous substances, and consequently by almost all animal liquors. We cannot easily form a very distinct and clear idea of the manner in which sulphur acts internally upon our bodies; but, from observations made upon its effects, it appears to be dividing, stimulating, and somewhat heating: it principally acts upon the perspirable parts of the body, the chief of which are the skin and lungs; and from this property it is particularly useful in some diseases of these parts. Sulphur is also a powerful repellent, as appears from its curing several kinds of itch, merely by external application, in form of ointments and pomatums. Several mineral waters, which are drunk or used as baths for some diseases, owe their good qualities to sulphur contained in them.

Sulphur is found sometimes pure, and sometimes in combination with other substances. Of native sulphur there are seven varieties; 1. Transparent sulphur, in eight-sided crystals, with two truncated pyramids. It is generally deposited by water on the surface of calcareous spar. Cadiz sulphur is of this kind. 2. Transparent sulphur in irregular fragments. Such is the sulphur of Switzerland. 3. Whitish pulverulent sulphur deposited in siliceous geodes. In the ci-devant Franche Comté there are flints full of sulphur. 4. Pulverulent sulphur deposited on the surface of mineral waters, such as those of Aix-la-Chapelle. 5. Crystalline sulphur that has been sublimed, found in the neighbourhood of volcanoes. 6. Pulverulent sulphur sublimed from volcanoes, found in abundance at Solfatara in the vicinity of Naples. See SOLFATARA. 7. Sulphur in stalactites, formed by volcanic fires. Sulphur is also found united with different substances, as with metals, and in this state was formerly called pyrites. See PYRITES. It is also extracted from vegetables, from dock-root, cochlearia, &c. M. Deyeux obtained it from the white of eggs. It has been also procured from horse dung. The sulphur used in Great Britain is generally brought in a pure state from volcanic countries, where it abounds in an inexhaustible quantity. Some of the metallic ores in this country abound with it; but, from the common mode of purifying them, the sulphur is dissipated and lost. Dr. Watson has shown, in a paper on lead ore in the Philosophical Transactions, that no less than 700 tons are annually dissipated in the various lead mines of England. It is extracted from pyrites in Saxony and Bohemia.

Sulphur is also used in several arts. By means of it fine impressions of engraved stones are taken. Matches are formed of it; and its utility as an ingredient in the preparation of gunpowder and fireworks is well known. Lastly, it is used for whitening wool, silk, and many other matters exposed to its vapor during its combustion; the colors and redness of which could not be destroyed by any other substance, but are quickly effaced by this acid vapor.

Of native or prismatic sulphur, says Dr. Ure, there are two species, the common and volcanic; the former is of two kinds, compact and earthy sulphur.

1. *Compact common sulphur*.—Color sulphur-yellow, and yellow of other shades. Massive, disseminated, and crystallised. Its primitive figure is a pyramid of $107^{\circ} 19'$; and $84^{\circ} 24'$; basis = $102^{\circ} 41'$. The secondary figures are, the primitive variously truncated or acuminated, and delicate acicular crystals. Shining or glimmering. Cleavage prismatic and axifrangible. Fracture uneven. Translucent. Refracts double. Harder than talc. Brittle. When rubbed, it exhales a faint sulphureous smell, and becomes resino-electric. Specific gravity 1.9 to 2.1. It occurs in considerable abundance in primitive mountains, in a state of combination with metals, forming the different genera of pyrites, glance, and blende. In secondary mountains it is more abundant in the pure uncombined state. It is found in the island of Iceland, associated

with gypsum; or in crusts investing alluvial substances. Very superb specimens of crystallised sulphur are found at Conil near Cape Trafalgar. It occurs abundantly in Sicily, at Urbino, in the Papal States, in Arragon in Spain, and Lauenstein in Hanover.

2. *Earthy common sulphur*.—Color pale straw-yellow. Massive and disseminated. Dull. Fracture fine earthy. Opaque. Does not soil. Soft to friable. It occurs in drusy cavities in flint, and along with the compact varieties in gypsum, and other rocks.

Volcanic sulphur.—Color pale sulphur-yellow. Massive, imitative, and crystallised in pyramids. Glistening, inclining to adamantine. Fracture uneven. Slightly translucent. It occurs abundantly at Solfatara, in the neighbourhood of Vesuvius, and in Iceland.

Sulphur is a simple inflammable body, of great importance in chemistry and the arts. To the properties above-mentioned we shall here add, that its fusing point is about 220° Fahrenheit, before which temperature it begins to evaporate. At 560° it takes fire in the open air, and burns with a pale blue flame. When kept melted in an open vessel for some time, about 300° Fahrenheit, it becomes thick and viscid; and, if it be then poured into a basin of water, it appears of a red color, and ductile like wax. In this state it is used for taking impressions of seals or medals. Its specific gravity is said to be increased from 1.99 to 2.325. This change is not owing to oxidation, for it takes place in close vessels. When a roll of sulphur is suddenly seized in a warm hand, it crackles, and sometimes falls in pieces. This is owing to the unequal action of heat, on a body which conducts that power slowly, and which has little cohesion. If a mass of sulphur be melted in a crucible, and, after the surface begins to concrete, if the liquid matter below be allowed to run out, fine acicular crystals of sulphur will be obtained.

Sulphur is insoluble in water; but in small quantity in alcohol and ether, and more largely in oil. It combines with oxygen in four definite proportions, constituting an interesting series of acids. See SULPHURIC ACID. From these combinations it is inferred, that the prime equivalent of sulphur is 2; and the density of its vapor is $1.111 =$ that of oxygen gas.

Sulphur combines readily with chlorine. This compound was first made by Dr. Thomson, who passed chlorine gas through flowers of sulphur. It may be made more expeditiously by heating sulphur in a retort containing chlorine. The sulphur and chlorine unite, and form a fluid substance, which is volatile below 200° Fahrenheit, and distils into the cold part of the retort. This substance, seen by reflected light, appears of a red color, but is yellowish-green when seen by transmitted light. It smokes when exposed to air, and has an odor somewhat resembling that of sea-weed, but much stronger; it affects the eyes like the smoke of peat. Its taste is acid, hot, and bitter. Its specific gravity is 1.7. It does not redden perfectly dry paper tinged with litmus; when it is agitated in contact with water, the water becomes cloudy from the ap-

S U L P H U R

pearance of sulphur, and strongly acid, and it is found to contain oil of vitriol. According to Sir H. Davy's experiments, ten grains of pure sulphur absorb nearly thirty cubic inches of chlorine, so that the compound contains about 2 sulphur to 4.5 chlorine, or a prime equivalent of each. The compound formed in the manner above described cannot be made to unite to more chlorine; but it can dissolve a considerable portion of sulphur by heat, and becomes of a tawny-yellow color.

Iodide of sulphur is easily formed by mixing the two ingredients in a glass tube, and exposing them to such a heat as melts the sulphur. It is grayish-black, and has a radiated structure like that of sulphuret of antimony. When distilled with water, iodine is disengaged.

Sulphur and hydrogen combine. Their union may be effected by causing sulphur to sublime in dry hydrogen in a retort. There is no change of volume, but only a part of the hydrogen can be united with the sulphur in this mode of operating. The usual way of preparing sulphuretted hydrogen is to pour a dilute sulphuric or muriatic acid on the black sulphuret of iron or antimony in a retort. For accurate experiments it should be collected over mercury. It takes fire when a lighted taper is brought in contact with it, and burns with a pale blue flame, depositing sulphur. Its smell is extremely fetid, resembling that of rotten eggs. Its taste is sour. It reddens vegetable blues. It is absorbable by water, which takes up more than an equal volume of the gas. Its specific gravity, according to M. M. Gay Lussac and Thenard, is to that of air as 1.1912 to 1.0. From Sir H. Davy's experiments, it would appear to be a little less, but he is inclined to adopt the results of the French chemists, rather than his own, as their gas was weighed in larger quantity and dried. Notwithstanding this preference of other experiments to his own, we must prefer a number nearer to Sir H. Davy's than M. Gay Lussac's. Its true specific gravity is 1.1805. 100 cubic inches weigh 36.006; and it consists of 1 vol. vapor of sulphur = 1.1111 + 1 vol. of hydrogen = 0.0694 = 1.1805; or a prime equivalent of each = 2.125. If platina wires be ignited in it by the voltaic apparatus, it is rapidly decomposed. Sulphur is deposited, and an equal volume of hydrogen remains. The same change is effected more slowly by electric sparks.

M. Berthier recommends the following process for procuring pure sulphuretted hydrogen at an economical rate:—Powdered common iron pyrites is to be mixed with half its weight of dry carbonate of soda, and heated red hot in a crucible; a fused sulphuret of sodium and iron is obtained, which may be poured out on a stone to cool. It is then a homogeneous deep-yellow colored mass, having a lamellar fracture. It absorbs much water, forming with it a black paste, which, when acted on by sulphuric or muriatic acid, instantly yields abundance of sulphuretted hydrogen; leaving a black sulphuret of iron, which, by the application of acid and heat, will yield a second portion of the gas. Sulphuret of lime, made by decomposing the sulphate at a high heat, with one-fifth of its

weight of charcoal, yields 46.8 per cent. of sulphuretted hydrogen, when acted on with dilute muriatic acid.—Ann. de Chimie, xxiv. 271.

When a few drops of fuming nitric acid are put into a flask filled with pure sulphuretted hydrogen, the hydrogen is oxidized by the nitric acid, and the sulphur is disengaged in a solid form. If the flask be closed with the finger, so that the gas which becomes heated cannot escape, its temperature is raised so much as to produce combustion with a beautiful flame, and a slight detonation which forces the finger from the mouth of the flask. This experiment may be made without the least danger, with a flask containing four or five cubical inches of gas.—Berzelius.

Of all the gases, sulphuretted hydrogen is perhaps the most deleterious to animal life. A greenfinch, plunged into air, which contains only $\frac{1}{1500}$ of its volume, perishes instantly. A dog of middle size is destroyed in air that contains $\frac{1}{500}$; and a horse would fall a victim to an atmosphere containing $\frac{1}{250}$.

Dr. Chaussier proves that, to kill an animal, it is sufficient to make the sulphuretted hydrogen gas act on the surface of its body, when it is absorbed by the inhalants. He took a bladder having a stop-cock at one end, and at the other an opening, into which he introduced the body of a rabbit leaving its head outside, and securing the bladder air-tight round the neck by adhesive plaster. He then sucked the air out of the bladder, and replaced it by sulphuretted hydrogen gas. A young animal in these circumstances usually perishes in fifteen or twenty minutes. Old rabbits resist the poison much longer. When potassium or sodium is heated, merely to fusion, in contact with sulphuretted hydrogen, it becomes luminous, and burns with extrication of hydrogen, while a metallic sulphuret remains, combined with sulphuretted hydrogen, or a sulphuretted hydrosulphuret. Sulphuretted hydrogen combines with an equal volume of ammonia, and unites to alkalies and oxides, so that it has all the characters of an acid. These compounds are called hydrosulphurets.

All the hydrosulphurets, soluble in water, have an acrid and bitter taste, and, when in the liquid state, the odor of rotten eggs. All those which are insoluble are, on the contrary, insipid, and without smell. There are only two colored hydrosulphurets, that of iron, which is black, and of antimony, which is chestnut-brown. All the hydrosulphurets are decomposed by the action of fire. That of magnesia is transformed into sulphuretted hydrogen and oxide of magnesium; those of potash and soda into sulphuretted hydrogen, hydrogen, and sulphuretted alkalies; those of manganese, zinc, iron, tin, and antimony, into water and metallic sulphurets. When we put in contact with the air, at the ordinary temperature, an aqueous solution of a hydrosulphuret, there results, in the space of some days, 1st. water, and a sulphuretted hydrosulphuret, which is yellow and soluble; 2dly, water, and a colorless hydrosulphite, which, if its base be potassa, soda, or ammonia, remains in solution in the water; but which falls down in acicular crystals, if its base be barytes, strontia,

or lime. The acids in general combine with the base of the hydrosulphurets, and disengage sulphuretted hydrogen with a lively effervescence, without any deposition of sulphur, unless the acid be in excess, and be capable, like the nitric and nitrous acid, of yielding a portion of its oxygen to the hydrogen of the sulphuretted hydrogen.

The hydrosulphurets of potash, soda, ammonia, lime, and magnesia, are prepared directly, by transmitting an excess of sulphuretted hydrogen gas through these bases, dissolved or diffused in water. The composition of the hydrosulphurets is such that the hydrogen of the sulphuretted hydrogen is to the oxygen of the oxide in the same ratio as in water. Hence, when we calcine the hydrosulphurets of iron, tin, &c., we convert them into water and sulphurets.

Hydrosulphuret of potash crystallises in four-sided prisms, terminated by four-sided pyramids. Its taste is acrid and bitter. Exposed to the air, it attracts humidity, absorbs oxygen, passes to the state of a sulphuretted hydrosulphuret, and finally to that of a hydrosulphite. It is extremely soluble in water. Its solution in this liquid occasions a perceptible refrigeration. Subjected to heat, it evolves much sulphuretted hydrogen, and the hydrosulphuret passes to the state of a sub-hydrosulphuret.

Hydrosulphuret of soda crystallises with more difficulty than the preceding.

Hydrosulphuret of ammonia is obtained by the direct union of the two gaseous constituents in a glass balloon, at a low temperature. As soon as the gases mingle, transparent white or yellowish crystals are formed. When a mere solution of this hydrosulphuret is wished for medicine or analysis, we pass a current of sulphuretted hydrogen through aqueous ammonia till saturation.

The pure hydrosulphuret is white, transparent, and crystallised in needles or fine plates. It is very volatile. Hence, at ordinary temperatures, it gradually sublimes into the upper part of the phials in which we preserve it. We may also by the same means separate it from the yellow sulphuretted hydrosulphuret, with which it is occasionally mixed. When exposed to the air, it absorbs oxygen, passes to the state of a sulphuretted hydrosulphuret, and becomes yellow. When it contains an excess of ammonia, it dissolves speedily in water, with the production of a very considerable cold.

Sub-hydrosulphuret of barytes is prepared by dissolving, in five or six parts of boiling water, the sulphuret of the earth obtained by igniting the sulphate with charcoal. The solution, being filtered while hot, will deposit, on cooling, a multitude of crystals, which must be drained, and speedily dried by pressure between the folds of blotting paper. It crystallises in white scaly plates. It is much more soluble in hot than in cold water. Its solution is colorless, and capable of absorbing, at the ordinary temperature, a very large quantity of sulphuretted hydrogen.

Sub-hydrosulphuret of strontites crystallises in the same manner as the preceding. The crystals obtained in the same way must be dissolved in water; and the solution being exposed to a stream of sulphuretted hydrogen, and then

concentrated by evaporation in a retort, will afford, on cooling, crystals of pure sub-hydrosulphuret. Hydrosulphurets of lime and magnesia have been obtained only in aqueous solutions. The metallic hydrosulphurets of any practical importance are treated of under their respective metals.

When we expose sulphur to the action of a solution of a hydrosulphuret, saturated with sulphuretted hydrogen, as much more sulphuretted hydrogen is evolved as the temperature is more elevated. But when the solution of hydrosulphuret, instead of being saturated, has a sufficient excess of alkali, it evolves no perceptible quantity of sulphuretted hydrogen, even at a boiling heat; although it dissolves as much sulphur as in its state of saturation. It hence follows, 1st. That sulphuretted hydrogen, sulphur, and the alkalies, have the property of forming very variable triple combinations; 2d. That all these combinations contain less sulphuretted hydrogen than the hydrosulphurets; and, 3d. That the quantity of sulphuretted hydrogen is inversely as the sulphur they contain, and reciprocally. These compounds have been called, in general, sulphuretted hydrosulphurets; but the name of hydrogenated sulphurets is more particularly given to those combinations which are saturated with sulphur at a high temperature, because, by treating them with acids, we precipitate a peculiar compound of sulphur and hydrogen, of which we shall now treat.

This compound of hydrogen and sulphur, the proportions of the elements of which have not yet been accurately ascertained, is also called hydruret of sulphur. It is formed by putting flowers of sulphur in contact with nascent sulphuretted hydrogen. With this view, we take an aqueous solution of the hydrogenated sulphuret of potash, and pour it gradually into liquid muriatic acid, which seizes the potash, and forms a soluble salt, whilst the sulphur and sulphuretted hydrogen unite, fall down together, collecting by degrees at the bottom of the vessel, as a dense oil does in water. To preserve this hydruret of sulphur, we must fill with it a phial having a ground stopper, cork it, and keep it inverted in a cool place. We may consider this substance either as a combination of sulphur and hydrogen, or of sulphur and sulphuretted hydrogen; but its properties, and the mode of obtaining it, render the latter the more probable opinion. The proportion of the constituents is not known.

The most interesting of the hydrogenated sulphurets is that of ammonia. It was discovered by the honorable Robert Boyle, and called his fuming liquor. To prepare it, we take one part of muriate of ammonia and of pulverised quicklime, and half a part of flowers of sulphur. After mixing them intimately, we introduce the mixture into an earthen or glass retort, taking care that none of it remains in the neck. A dry cooled receiver is connected to the retort by means of a long adapter-tube. The heat must be urged slowly almost to redness. A yellowish liquor condenses in the receiver, which is to be put into a phial with its own weight of flowers of sulphur, and agitated with it seven or eight

minutes. The greater part of the sulphur is dissolved, the color of the mixture deepens remarkably, and becomes thick, constituting the hydrogenated sulphuret. The distilled liquor diffuses, for a long time, dense vapor in a jar full of oxygen or common air; but scarcely any in azote or hydrogen; and the dryness or humidity of the gases makes no difference in the effects. It is probably owing to the oxygen converting the liquor into a hydrogenated sulphuret, or perhaps to the state of sulphite, that the vapors appear. Hydrogenated sulphurets are frequently called hydroguretted sulphurets. Sulphur combines with carbon, forming an interesting compound, to which the name of sulphuret of carbon is sometimes given.

SULPHUR ISLAND, an island of the North Pacific Ocean, discovered by captain Gore, in 1779; about five miles long, in a N. N. E. and S. S. W. direction. The south point is a high barren hill, flat at top, and presents an evident volcanic crater. Long. $141^{\circ} 12' E.$, lat. $24^{\circ} 28' N.$

SULPHUR MOUNTAIN, in geology, a volcanic mountain, frequently found in the islands of the Western Atlantic, perpetually throwing forth sulphurous or sulphuric exhalations from fissures or a direct crater; and which exhalations often concrete and form beautiful crystals on the surrounding parts of the mountain. The best description we have met with of these sulphur mountains is given by Dr. Nugent, and published as follows in the Transactions of the Geological Society, vol. i.

‘On my voyage last year (October 1810) from Antigua to England, the packet touched at Montserrat, and my curiosity having been excited by the accounts I received of a place in the island called The Sulphur, and which, from the descriptions of several persons, I conceived might be the crater of an inconsiderable volcano, I determined to avail myself of the stay of the packet to visit that place.

‘The island of Montserrat, so called by the Spaniards from a fancied resemblance to the celebrated mountain of Catalonia, is every where extremely rugged and mountainous, and the only roads, except in one direction, are narrow bridle-paths winding through the recesses of the mountains: there is hardly a possibility of using wheeled carriages, and the produce of the estates is brought to the place of shipment on the backs of mules. Accompanied by a friend, I accordingly set out on horseback from the town of Plymouth, which is situated at the foot of the mountains on the sea shore. We proceeded by a circuitous and steep route about six miles, gradually ascending the mountain, which consisted entirely of a uniform porphyritic rock, broken every where into fragments and large blocks, and which in many places was so denuded of soil as to render it a matter of astonishment how vegetation, and particularly that of the cane, should thrive so well. The far greater part of the whole island is made up of this porphyry, which by some systematics would be considered as referrible to the newest floetz trap formation, and by others would be regarded only as a variety of lava. It is a compact and highly indurated argillaceous rock of a gray color, replete with large

and perfect crystals of white felspar and black hornblende. Rocks of this description generally pass in the West Indies by the vague denomination of fire-stone, from the useful property they possess of resisting the operation of intense heat. A considerable quantity of this stone is accordingly exported from Montserrat to the other islands which do not contain it, being essential in forming the masonry around the copper boilers in sugar works. We continued our ride a considerable distance beyond the estate called Galloway’s (where we procured a guide), till we came to the side of a very deep ravine which extends in a winding direction the whole way from one of the higher mountains to the sea. A rugged horse-path was traced along the brink of the ravine, which we followed, amidst the most beautiful and romantic scenery. At the head of this ravine is a small amphitheatre, formed by lofty surrounding mountains, and here is situated what is termed The Sulphur. Though the scene was extremely grand, and well worthy of observation, yet I confess I could not help feeling a good deal disappointed, as there was nothing like a crater to be seen, or any thing else that could lead me to suppose the place had any connexion with a volcano. On the north, east, and west sides were lofty mountains wooded to the tops, composed apparently of the same kind of porphyry we had noticed all along the way. On the south the same kind of rock, of no great height, quite bare of vegetation, and in a very peculiar state of decomposition. And, on the south-eastern side, our path and the outlet into the ravine. The whole area thus included might be 300 or 400 yards in length, and half that distance in breadth. The surface of the ground, not occupied by the ravine, was broken and strewed with fragments and masses of the porphyritic rock, for the most part so exceedingly decomposed as to be friable and to crumble on the smallest pressure. For some time I thought that this substance, which is perfectly white, and in some instances exhibits an arrangement like crystals, was a peculiar mineral; but afterwards became convinced that it was merely the porphyritic rock singularly altered, not by the action of the air or weather, but, as I conjecture, by a strong sulphureous or sulphuric acid vapor which is generated here, and which is probably driven more against one side by the eddy wind up the ravine, the breeze from any other quarter being shut out by the surrounding hills.

‘Amidst the loose stones and fragments of decomposed rock are many fissures and crevices, whence very strong sulphureous exhalations arise, and which are diffused to a considerable distance: these exhalations are so powerful as to impede respiration, and near any of the fissures are quite intolerable and suffocating. The buttons of my coat, and some silver and keys in my pockets, were instantaneously discolored. An intense degree of heat is at the same time evolved, which, added to the apprehension of the ground crumbling and giving way, renders it difficult and painful to walk near any of these fissures. The water of a rivulet which flows down the sides of the mountain, and passes over

this place, is made to boil with violence, and becomes loaded with sulphureous impregnations. Other branches of the same rivulet, which do not pass immediately near these fissures, remain cool and limpid; and thus you may with one hand touch one rill which is at the boiling point, and with the other hand touch another rill which is of the usual temperature of water in that climate. The exhalations of sulphur do not at all times proceed from the same fissures, but new ones appear to be daily formed, others becoming, as it were, extinct. On the margins of these fissures, and indeed almost over the whole place, are to be seen most beautiful crystallisations of sulphur, in many spots quite as fine and perfect as those from Vesuvius, or indeed as any other specimens I have ever met with. The whole mass of decomposed rock in the vicinity is, in like manner, quite penetrated by sulphur. I did not perceive at this place any trace of pyrites, or any other metallic substance, except indeed two or three small fragments of clay iron-stone at a little distance, but did not discover even this substance any where in situ. It is very probable that the bed of the glen or ravine might throw some light on the internal structure of the place; but it was too deep, and its banks infinitely too precipitous, for me to venture down to it. I understood that there was a similar exhalation and deposition of sulphur on the side of a mountain not more than a mile distant in a straight line; and a subterranean communication is supposed to exist between the two places.

'Almost every island in the western Archipelago, particularly those which have the highest land, has in like manner its sulphur, or, as the French better express it, its *souffrière*. This is particularly the case with Nevis, St. Kitts, Guadaloupe, Dominica, Martinico, St. Lucia, and St. Vincent's. Some islands have several such places, analogous, I presume, to this of Montserrat; but in others, as Guadaloupe, St. Lucia, and St. Vincent's, there are decided and well characterised volcanos, which are occasionally active, and throw out ashes, scorïæ, and lava with flame. The volcano of St. Vincent's is represented by Dr. Anderson, and others who have visited it, as extremely large and magnificent, and would bear a comparison with some of those of Europe. These circumstances appear to have been entirely overlooked by geologists in their speculations concerning the origin and formation of these islands. It has indeed occurred to most persons, on surveying the regular chain of islands extending from the southern Cape of Florida to the mouths of the Orinoco, as exhibited on the map, to conclude that it originally formed part of the American continent, and that the encroachments of the sea have left only the higher parts of the land, as insular points above its present level. But this hypothesis, however simple and apparently satisfactory in itself, will be found to accord very partially with the geological structure of the different islands. Many of them are made entirely of vast accretions of marine organized substances; and others evidently owe their origin to a volcanic agency, which is either in some degree apparent at the present time, or else may be readily traced by vestiges compara-

tively recent. There is every reason to believe, however, that some of the islands are really of contemporaneous formation with the adjacent parts of the continent, from which they have been disjoined by the incursions of the sea, or by convulsions of nature, and it is probably in those islands which contain primitive rocks that we are chiefly to look for a confirmation of this supposition.

SULPHURET OF LIME having been recommended by Mr. Higgins as a substitute for potash in the new method of bleaching, which, if it answer, may certainly be afforded at less expense, we shall here give the method of preparing the sulphuret. Take of sulphur, or brimstone in fine powder, four pounds; lime well slaked and sifted twenty pounds; water sixteen gallons: these are all to be well mixed and boiled for about half an hour in an iron vessel, stirring them briskly from time to time. Soon after the agitation of the boiling is over, the solution of the sulphuret of the lime clears, and may be drawn off free from the insoluble matter, which is considerable, and which rests upon the bottom of the boiler. The liquor in this state is pretty nearly of the color of small beer, but not quite so transparent. Sixteen gallons of fresh water are afterwards to be poured upon the insoluble dregs in the boiler, to separate the whole of the sulphuret from them. When this clears (being previously well agitated) it is also to be drawn off and mixed with the first liquor; to these again thirty-three gallons more of water may be added, which will reduce the liquor to a proper standard for steeping the cloth. Here we have (an allowance being made for evaporation, and for the quantity retained in the dregs) sixty gallons of liquor from four pounds of brimstone. Although sulphur by itself is not in any sensible degree soluble in water, and lime but very sparingly so, water dissolving but about $\frac{1}{700}$ th part of its weight of lime; yet the sulphuret of lime is highly soluble. When the above proportion of lime and sulphur is boiled with only twelve gallons of water, the sulphuret partly crystallises upon cooling; and when once crystallised it is not easy of solution.

SULPHURETS OF ALKALIES AND EARTHS. Heretofore these were reckoned compounds of the alkalies and earths themselves with sulphur, that is, sulphureted oxides; but M. Berthier has proved that they are all true metallic sulphurets. He reduces the sulphates of alkalies into sulphurets, not by mixing them directly with powdered charcoal, but by placing them in the centre of a crucible thickly lined with charcoal, covering them with the same substance, and, after having luted on a cover, heating the whole in a furnace. In this way the sulphates are reduced by cementation. All are reducible at a white heat, and where the sulphuret is fusible very quickly. In this way not only are pure sulphurets formed, but the result may be collected without the smallest loss, its weight ascertained, and the weight of oxygen evolved accurately estimated.

If a sulphate of barytes, strontites, or lime, be thus reduced to a sulphuret, and weighed, the loss will be found to equal exactly the quantity of oxygen contained in the base and the acid. If

the sulphuret be dissolved in dilute muriatic acid, nothing will be liberated but pure sulphureted hydrogen; no sulphur will be set free, nor any acid containing sulphur and oxygen formed; finally, if a portion of the sulphuret be heated in a crucible of silver, with nitre equal to three or four times its weight, the sulphate regenerated will correspond with the quantity of sulphuret employed, and will contain neither acid nor base in excess. These three experiments prove that the sulphuret produced contains no oxygen.

SULPHURIC ACID. Oil of vitriol. Vitriolic acid. When sulphur is heated to 180° or 190° in an open vessel, it melts, and soon afterwards emits a bluish flame, visible in the dark, but which, in open day-light has the appearance of a white fume. This flame has a suffocating smell, and has so little heat that it will not set fire to flax, or even gunpowder, so that in this way the sulphur may be entirely consumed out of it. If the heat be still augmented, the sulphur boils and suddenly bursts into a much more luminous flame, the same suffocating vapor still continuing to be emitted. The suffocating vapor of sulphur is imbibed by water, with which it forms the fluid formerly called volatile vitriolic, now sulphurous acid. If this fluid be exposed for a time to the air it loses the sulphurous smell it had at first, and the acid becomes more fixed. It is then the fluid which was formerly called the spirit of vitriol. Much of the water may be driven off by heat, and the dense acid which remains is the sulphuric acid, commonly called oil of vitriol; a name which was probably given to it from the little noise it makes when poured out, and the unctuous feel it has when rubbed between the fingers, produced by its corroding and destroying the skin, with which it forms a soapy compound.

The stone or mineral called martial pyrites, which consists for the most part of sulphur and iron, is found to be converted into the salt vulgarly called green vitriol, but more properly sulphate of iron, by exposure to air and moisture. In this natural process the pyrites breaks and falls in pieces; and if the change takes place rapidly a considerable increase of temperature follows, which is sometimes sufficient to set the mass on fire. By conducting this operation in an accurate way it is found that oxygen is absorbed. The sulphate is obtained by solution in water and subsequent evaporation; by which the crystals of the salt are separated from the earthy impurities which were not suspended in the water.

The sulphuric acid was formerly obtained in this country by distillation from sulphate of iron, as it still is in many parts abroad: the common green vitriol is made use of for this purpose, as it is to be met with at a low price and the acid is most easily to be extracted from it. With respect to the operation itself the following particulars should be attended to:—First the vitriol must be calcined in an iron or earthen vessel till it appears of a yellowish-red color: by this operation it will lose half its weight. This is done in order to deprive it of the greater part of the water which it has attracted into its crystals during the crystallisation, and which would other-

wise, in the ensuing distillation, greatly weaken the acid. As soon as the calcination is finished the vitriol is to be put immediately, while it is warm, into a coated earthen retort, which is to be filled two-thirds with it, so that the ingredients may have sufficient room upon being distended by the heat, and thus the bursting of the retort be prevented. It will be most advisable to have the retort immediately enclosed in brickwork in a reverberatory furnace, and to stop up the neck of it till the distillation begins, in order to prevent the materials from attracting fresh humidity from the air. At the beginning of the distillation the retort must be opened and a moderate fire is to be applied to it, in order to expel from the vitriol all that part of the phlegm which does not taste strongly of the acid, and which may be received in an open vessel placed under the retort. But as soon as there appear any acid drops, a receiver is to be added, into which has been previously poured a quantity of the acidulous fluid which has come over, in the proportion of half a pound of it to twelve pounds of the calcined vitriol; when the receiver is to be secured with a proper luting. The fire is now to be raised by little and little to the most intense degree of heat, and the receiver carefully covered with wet cloths, and, in winter time, with snow or ice, as the acid rises in the form of a thick white vapor, which toward the end of the operation becomes hot and heats the receiver to a great degree. The fire must be continued at this high pitch for several days till no vapor issues from the retort, nor any drops are seen trickling down its sides. In the case of a great quantity of vitriol being distilled, Bernhardt has observed it to continue emitting vapors in this manner for the space of ten days. When the vessels are quite cold the receiver must be opened carefully, so that none of the luting may fall into it; after which the fluid contained in it is to be poured into a bottle and the air carefully excluded. The fluid that is thus obtained is the German sulphuric acid, of which Bernhardt got sixty-four pounds from 600 cwt. of vitriol; and, on the other hand, when no water had been previously poured into the receiver, fifty-two pounds only of a dry concrete acid. This acid was formerly called glacial oil of vitriol, and its consistence is owing to a mixture of sulphurous acid, which occasions it to become solid at a moderate temperature.

It has been lately stated by Vogel that when this fuming acid is put into a glass retort, and distilled by a moderate heat into a receiver cooled with ice, the fuming portion comes over first, and may be obtained in a solid state by stopping the distillation in time. This has been supposed to constitute absolute sulphuric acid, or acid entirely void of water. It is in silky filaments, tough, difficult to cut, and somewhat like asbestos. Exposed to the air it fumes strongly and gradually evaporates. It does not act on the skin so rapidly as concentrated oil of vitriol. Up to 66° it continues solid, but at temperatures above this it becomes a colorless vapor, which whitens on contact with air. Dropped into water in small quantities it excites a hissing noise as if it were red-hot iron; in larger quantities it produces a species of explosion. It

is said to be convertible into ordinary sulphuric acid by the addition of a fifth of water. It dissolves sulphur, and assumes a blue, green, or brown color, according to the proportion of sulphur dissolved. The specific gravity of the black fuming sulphuric acid, prepared in large quantities from copperas at Nordhausen, is 1.896. Its constitution is not well ascertained.

The sulphuric acid made in Great Britain is produced by the combustion of sulphur. There are three conditions requisite in this operation. Oxygen must be present to maintain the combustion; the vessel must be so close as to prevent the escape of the volatile matter which rises, and water must be present to imbibe it. For these purposes a mixture of eight parts of sulphur with one of nitre is placed in a proper vessel, enclosed within a chamber of considerable size, lined on all sides with lead, and covered at bottom with a shallow stratum of water. The mixture being set on fire will burn for a considerable time by virtue of the supply of oxygen which nitre gives out when heated, and the water imbibing the sulphurous vapors becomes gradually more and more acid after repeated combustions, and the acid is afterward concentrated by distillation. Such was the account usually given of this operation till Clement and Desormes showed, in a very interesting memoir, its total inadequacy to account for the result. 100 parts of nitre, judiciously managed, will produce, with the requisite quantity of sulphur, 2000 parts of concentrated sulphuric acid. Now these contain 1200 parts of oxygen, while the 100 parts of nitre contain only thirty-nine and a half of oxygen; being not one-thirtieth part of what is afterwards found in the resulting sulphuric acid. But after the combustion of the sulphur the nitre is converted into sulphate and bisulphate of potassa, which mingled residuary salts contain nearly as much oxygen as the nitre originally did. Hence the origin of the 1200 parts of the oxygen in the sulphuric acid is still to be sought for. The following ingenious theory was first given by Clement and Desormes:—The burning sulphur, or sulphurous acid, taking from the nitre a portion of its oxygen, forms sulphuric acid, which unites with the potassa, and displaces a little nitrous and nitric acids in vapor. These vapors are decomposed by the sulphurous acid into nitrous gas, or deutoxide of azote. This gas, naturally little denser than air, and now expanded by the heat, suddenly rises to the roof of the chamber, and might be expected to escape at the aperture there which manufacturers were always obliged to leave open, otherwise they found the acidification would not proceed. But, the instant that nitrous gas comes in contact with atmospheric oxygen, nitrous acid vapor is formed, which, being a very heavy æriiform body, immediately precipitates on the sulphurous flame and converts it into sulphuric acid; while itself resuming the state of nitrous gas reascends for a new charge of oxygen, again to reascend and transfer it to the flaming sulphur. Thus we see that a small volume of nitrous vapor, by its alternate metamorphoses into the states of oxide and acid, and its consequent interchanges, may be capable of acidifying a great quantity of sulphur.

This beautiful theory received a modification from Sir H. Davy. He found that nitrous gas had no action on sulphurous gas, to convert it into sulphuric acid, unless water be present. With a small proportion of water, four volumes of sulphurous acid gas and three of nitrous gas are condensed into a crystalline solid, which is instantly decomposed by abundance of water; oil of vitriol is formed, and nitrous gas given off, which with contact of air becomes nitrous acid gas, as above described. The process continues, according to the same principle of combination and decomposition, till the water at the bottom of the chamber is become strongly acid. It is first concentrated in large leaden pans, and afterwards in glass retorts heated in a sand bath. Platinum alembics, placed within pots of cast-iron of a corresponding shape and capacity, have been lately substituted in many manufactories for glass, and have been found to save fuel and quicken the process of concentration.

The proper mode of burning the sulphur with the nitre, so as to produce the greatest quantity of oil of vitriol, is a problem concerning which chemists hold a variety of opinions. Thebard describes the following as the best:—Near one of the sides of the leaden chamber, and about a foot above its bottom, an iron plate, furnished with an upright border, is placed horizontally over a furnace, whose chimney passes across, under the bottom of the chamber, without having any connexion with it. On this plate, which is enclosed in a little chamber, the mixture of sulphur and nitre is laid. The whole being shut up, and the bottom of the large chamber covered with water, a gentle fire is kindled in the furnace. The sulphur soon takes fire, and gives birth to the products described. When the combustion is finished, which is seen through a little pane adapted to the trap-door of the chamber, this is opened, the sulphate of potassa is withdrawn, and is replaced by a mixture of sulphur and nitre. The air in the great chamber is meanwhile renewed by opening its lateral door and a valve in its opposite side. Then, after closing these openings, the furnace is lighted anew. Successive mixtures are thus burned, till the acid acquires a specific gravity of about 1.390, taking care never to put at once on the plate more sulphur than the air of the chamber can acidify. The acid is then withdrawn by stopcocks and concentrated.

The following details are extracted from a paper on sulphuric acid, which Dr. Ure published in the fourth volume of the *Journal of Science and the Arts*:—‘The best commercial sulphuric acid that I have been able to meet with,’ says he, ‘contains from one-half to three-quarters of a part in the 100 of solid saline matter, foreign to its nature. These fractional parts consist of sulphate of potassa and lead, in the proportion of four of the former to one of the latter. I, is, I believe, difficult to manufacture it directly, by the usual methods, of a purer quality. The ordinary acid sold in the shops contains often three or four per cent. of saline matter. Even more is occasionally introduced, by the employment of nitre, to remove the brown color given to the acid by carbonaceous matter. The amount of these adulterations, whether acci-

dental or fraudulent, may be readily determined by evaporating, in a small capsule of porcelain, or rather platinum, a definite weight of the acid. The platinum cup placed on the red cinders of a common fire will give an exact result in five minutes. If more than five grains of matter remain from 500 of acid we may pronounce it sophisticated.

Distillation is the mode by which pure oil of vitriol is obtained. This process is described in chemical treatises as both difficult and hazardous; but since adopting the following plan I have found it perfectly safe and convenient:—I take a plain glass retort, capable of holding from two to four quarts of water, and put into it about a pint measure of the sulphuric acid (and a few fragments of glass), connecting the retort with a large globular receiver, by means of a glass tube four feet long, and from one to two inches in diameter. The tube fits very loosely at both ends. The retort is placed over a charcoal fire, and the flame is made to play gently on its bottom. When the acid begins to boil smartly, sudden explosions of dense vapor rush forth from time to time, which would infallibly break small vessels. Here, however, these expansions are safely permitted, by the large capacity of the retort and receiver, as well as by the easy communication with the air at both ends of the adapter tube. Should the retort, indeed, be exposed to a great intensity of flame, the vapor will no doubt be generated with incoercible rapidity and break the apparatus. But this accident can proceed only from gross imprudence. It resembles, in suddenness, the explosion of gunpowder, and illustrates admirably Dr. Black's observation that, but for the great latent heat of steam, a mass of water, powerfully heated, would explode on reaching the boiling temperature. I have ascertained that the specific caloric of the vapor of sulphuric acid is very small, and hence the danger to which rash operators may be exposed during its distillation. Hence, also, it is unnecessary to surround the receiver with cold water, as when alcohol and most other liquids are distilled. Indeed the application of cold to the bottom of the receiver generally causes it, in the present operation, to crack. By the above method I have made the concentrated oil of vitriol flow over in a continuous slender stream, without the globe becoming sensibly hot.

I have frequently boiled the distilled acid till only one-half remained in the retort; yet at the temperature of 60° Fahrenheit I have never found the specific gravity of acid so concentrated, to exceed 1·8455. It is, I believe, more exactly 1·8452. The number 1·850, which it has been the fashion to assign for the density of pure oil of vitriol, is undoubtedly very erroneous and ought to be corrected. Genuine commercial acid should never surpass 1·8485; when it is denser we may infer sophistication, or negligence, in the manufacture.

The sulphuric acid strongly attracts water, which it takes from the atmosphere very rapidly, and in larger quantities, if suffered to remain in an open vessel, imbibing one-third of its weight in twenty-four hours, and more than six times its weight in a twelvemonth. If four parts by

weight be mixed with one of water at 50° they produce an instantaneous heat of 300° Fahrenheit; and four parts raise one of ice to 212°: on the contrary, four parts of ice mixed with one of acid sink the thermometer to 4° below 0. When pure it is colorless and emits no fumes. It requires a great degree of cold to freeze it; and if diluted with half a part or more of water, unless the dilution be carried very far, it becomes more and more difficult to congeal; yet at the specific gravity of 1·78, or a few hundredths above or below this, it may be frozen by surrounding it with melting snow. Its congelation forms regular prismatic crystals with six sides. Its boiling point, according to Bergman, is 540°, according to Dalton 590°.

Pure sulphuric acid is without smell and color, and of an oily consistence. Its action on litmus is so strong that a single drop of acid will give to an immense quantity of water the power of reddening. It is a most violent caustic, and has sometimes been administered with the most criminal purposes. The person who unfortunately swallows it speedily dies in dreadful agonies and convulsions. Chalk, or common carbonate of magnesia, is the best antidote for this as well as for the strong nitric and muriatic acids. When transmitted through an ignited porcelain tube, of one-fifth of an inch diameter, it is resolved into two parts of sulphurous acid gas, and one of oxygen gas, with water. Voltaic electricity causes an evolution of sulphur at the negative pole; whilst a sulphate of the metallic wire is formed at the positive. Sulphuric acid has no action on oxygen gas or air. It merely abstracts their aqueous vapor.

If the oxygenised muriatic acid of Thenard be put in contact with the sulphate of silver there is immediately formed insoluble chloride, of silver and oxygenised sulphuric acid. To obtain sulphuric acid in the highest degree of oxygenation, it is merely necessary to pour barytes water into the above oxygenised acid, so as to precipitate only a part of it, leaving the rest in union with the whole of the oxygen. Oxygenised sulphuric acid partially reduces the oxide of silver, occasioning a strong effervescence.

All the simple combustibles decompose sulphuric acid with the assistance of heat. About 400° Fahrenheit sulphur converts sulphuric into sulphurous acid. Several metals at an elevated temperature decompose this acid, with evolution of sulphurous acid gas, oxidisement of the metal, and combination of the oxide with the undecomposed portion of the acid.

The sulphuric acid is of very extensive use in the art of chemistry, as well as in metallurgy, bleaching, and some of the processes for dyeing; in medicine it is given as a tonic and stimulant, and is sometimes used externally as a caustic. The combinations of this acid with the various bases are called sulphates, and most of them have long been known by various names. With barytes it is found native and nearly pure in various forms; in coarse powder, rounded masses, stalactites, and regular crystallisations, which are in some lamellar, in others needly, in others prismatic or pyramidal. This salt, if at all deleterious, is less so than the car-

bonate of barytes, and is more economical for preparing the muriate for medicinal purposes. It requires 43,000 parts of water to dissolve it at 60°.

Sulphate of strontian has a considerable resemblance to that of barytes in its properties. It is found native in considerable quantities at Aust Passaie and other places in the neighbourhood of Bristol. It requires 3840 parts of boiling water to dissolve it. Its composition is 5 acid + 6.5 base.

The sulphate of potassa, vitriolated kali, formerly vitriolated tartar, sal de duobus, and arcanum duplicatum, crystallises in hexahedral prisms, terminated by hexagonal pyramids, but susceptible of variations. Its crystallisation by quick cooling is confused. Its taste is bitter, acrid, and a little saline. It is soluble in five parts of boiling water, and sixteen parts at 60°. In the fire it decrepitate, and is fusible by a strong heat. It is decomposable by charcoal at a high temperature. It may be prepared by direct mixture of its component parts; but the usual and cheapest mode is to neutralise the acidulous sulphate left after distilling nitric acid, the sal enixen of the old chemists, by the addition of carbonate of potassa. The sal polychrest of old dispensaries, made by deflagrating sulphur and nitre in a crucible, was a compound of the sulphate and sulphite of potassa. The acidulous sulphate is sometimes employed as a flux, and likewise in the manufacture of alum. In medicine, the neutral salt is sometimes used as a deobstruent, and in large doses as a mild cathartic; dissolved in a considerable portion of water, and taken daily in such quantity as to be gently aperient, it has been found serviceable in cutaneous affections, and is sold in London for this purpose as a nostrum; and certainly it deserves to be distinguished from the generality of quack-medicines, very few indeed of which can be taken without imminent hazard. It consists of 5 acid + 6 base; but there is a compound of the same constituents, in the proportion of 10 acid + 6 potassa, called the bisulphate.

The sulphate of soda is the vitriolated natron of the college, the well known Glauber's salt, or sal mirabile. It is commonly prepared from the residuum left after distilling muriatic acid, the superfluous acid of which may be saturated by the addition of soda, or precipitated by lime; and is likewise obtained in the manufacture of the muriate of ammonia. Scherer mentions another mode by Funcke, which is, making eight parts of calcined sulphate of lime, five of clay, and five of common salt, into a paste with water; burning this in a kiln; and then powdering, lixiviating, and crystallising. It exists in large quantities under the surface of the earth in some countries, as Persia, Bohemia, and Switzerland; is found mixed with other substances in mineral springs and sea water; and sometimes effloresces on walls. Sulphate of soda is bitter and saline to the taste. It is soluble in 2.85 parts of cold water, and 0.8 at a boiling heat. It crystallises in hexagonal prisms bevelled at the extremities, sometimes grooved longitudinally, and of very large size, when the quantity is great. These effloresce completely into a white powder if ex-

posed to a dry air, or even if kept wrapped up in paper in a dry place; yet they retain sufficient water of crystallisation to undergo the aqueous fusion on exposure to heat; but, by urging the fire, melt. Barytes and strontian take their acid from it entirely, and potassa partially; the nitric and muriatic acids, though they have a weaker affinity for its base, combine with a part of it when digested on it. Heated with charcoal its acid is decomposed. As a purgative its use is very general; and it has been employed to furnish soda. Pajot des Charmes has made some experiments on it in fabricating glass; with sand alone it would not succeed, but equal parts of carbonate of lime, sand, and dried sulphate of soda, produced a clear, solid, pale, yellow glass. It is composed of 5 acid + 4 base + 11.25 water in crystals; when dry, the former two primes are its constituents. Sulphate of soda and sulphate of ammonia form together a triple salt.

Sulphate of lime, selenite, gypsum, plaster of Paris, or sometimes alabaster, forms extensive strata in various mountains. The specular gypsum, or glacies Mariæ, is a species of this salt, and affirmed by some French travellers to be employed in Russia, where it abounds, as a substitute for glass in windows. Its specific gravity is from 1.872 to 2.311. It requires 500 parts of cold water, and 450 of hot, to dissolve it. When calcined, it decrepitate, becomes very friable and white, and heats a little with water, with which it forms a solid mass. In this process it loses its water of crystallisation. In this state it is found native in Tyrol, crystallised in rectangular parallelepipeds, or octahedral or hexahedral prisms, and is called anhydrous sulphate of lime. Both the natural and artificial anhydrous sulphate consists of 56.3 lime, and 43.6 acid, according to Chenevix. The calcined sulphate is much employed for making casts of anatomical and ornamental figures; as one of the bases of stucco; as a fine cement for making close and strong joints between stone, and joining rims or tops of metal to glass; for making moulds for the Staffordshire potteries; for cornices, mouldings, and other ornaments in building. For these purposes, and for being wrought into columns, chimney-pieces, and various ornaments, about 800 tons are raised annually in Derbyshire, where it is called alabaster. In America it is laid on grass land as a manure. Ordinary crystallised gypsum consists of 5 sulphuric acid + 3.5 lime + 2.25 water; the anhydrous variety wants of course the last ingredient.

Sulphate of magnesia, the vitriolated magnesia of the late, and sal catharticus amarus of former London Pharmacopœias, is commonly known by the name of Epsom salt, as it was furnished in considerable quantity by the mineral water at that place, mixed, however, with a considerable portion of sulphate of soda. It is afforded, however, in greater abundance, and more pure, from the bitters left after the extraction of salt from sea water. It has likewise been found efflorescing on brick walls, both old and recently erected, and in small quantity in the ashes of coals. The capillary salt of Idria, found in silvery crystals mixed with the aluminous schist in the mines of

that place, and hitherto considered as a feathery alum, has been ascertained by Klaproth to consist of sulphate of magnesia, mixed with a small portion of sulphate of iron. When pure, it crystallises in small quadrangular prisms, terminated by quadrangular pyramids or dihedral summits. Its taste is cool and bitter. It is very soluble, requiring only an equal weight of cold water, and three-fourths its weight of hot. It effloresces in the air, though but slowly. If it attract moisture, it contains muriate of magnesia or of lime. Exposed to heat, it dissolves in its own water of crystallisation, and dries, but is not decomposed nor fused, but with extreme difficulty. It consists, according to Bergman, of 33 acid, 19 magnesia, 48 water. A very pure sulphate is said to be prepared in the neighbourhood of Genoa, by roasting a pyrites found there; exposing it to the air in a covered place for six months; watering it occasionally, and then lixiviating. Sulphate of magnesia is one of our most valuable purgatives; for which purpose only it is used, and for furnishing the carbonate of magnesia. It is composed of 5 acid + 2.5 magnesia + 7.875 water, in the state of crystals.

Sulphate of ammonia crystallises in slender, flattened, hexahedral prisms, terminated by hexagonal pyramids; it attracts a little moisture from very damp air, particularly if the acid be in excess; it dissolves in two parts of cold, and one of boiling, water. It is not used, though Glauber, who called it his secret ammoniacal salt, vaunted its excellence in assaying. It consists of 5 acid + 2.125 ammonia + 1.125 water in its most desiccated state; and in its crystalline state of 5 acid + 2.125 ammonia + 3.375 water. If sulphate of ammonia and sulphate of magnesia be added together in solution, they combine into a triple salt of an octahedral figure, but varying much; less soluble than either of its component parts; unalterable in the air; undergoing on the fire the watery fusion; after which it is decomposed, part of the ammonia flying off, and the remainder subliming with an excess of acid. It contains, according to Fourcroy, 68 sulphate of magnesia, and 32 sulphate of ammonia.

Sulphate of glucina crystallises with difficulty, its solution readily acquiring and retaining a syrupy consistence; its taste is sweet, and slightly astringent; it is not alterable in the air; a strong heat expels its acid, and leaves the earth pure; heated with charcoal, it forms a sulphuret; infusion of galls forms a yellowish-white precipitate with its solution.

Ytria is readily dissolved by sulphuric acid; and, as the solution goes on, the sulphate crystallises in small brilliant grains, which have a sweetish taste, but less so than sulphate of glucina, and are of a light amethyst-red color. They require thirty parts of cold water to dissolve them, and give up their acid when exposed to a high temperature. They are decomposed by oxalic acid, prussiate of potassa, infusion of galls, and phosphate of soda.

Sulphate of alumina in its pure state is but recently known, and it was first attentively examined by Vauquelin. It may be made by dissolving pure alumina in pure sulphuric acid, heating them for some time, evaporating the solution to

dryness, drying the residuum with a pretty strong heat, redissolving it, and crystallising. Its crystals are soft, foliaceous, shining, and pearly; but these are not easily obtained without cautious evaporation and refrigeration. They have an astringent taste; are little alterable in the air; are pretty soluble, particularly in hot water; give out their acid on exposure to a high temperature; are decomposable by combustible substances, though not readily; and do not form a pyrophorus like alum. If the evaporation and desiccation directed above be omitted, the alumina will remain supersaturated with acid, as may be known by its taste, and by its reddening vegetable blue. This is still more difficult to crystallise than the neutral salt, and frequently thickens into a gelatinous mass. A compound of acidulous sulphate of alumina, with potassa or ammonia, has long been known by the name of alum.

Sulphate of zircon may be prepared by adding sulphuric acid to the earth recently precipitated, and not yet dry. It is sometimes in small needles, but commonly pulverulent; very friable; insipid; insoluble in water, unless it contain some acid; and easily decomposed by heat. Sulphuric acid is a powerful antiseptic and tonic: it is given, properly diluted, in the dose of from one to three drops with cinchona and other medicines in the cure of fevers and debilities, and it is often applied externally, when very much diluted, against psora and some chronic affections of the skin.

SULPHURIC ETHER, and SULPHURIC SALTS. See CHEMISTRY, INDEX.

SULPHUROPRUSSIC ACID. The sulphureted chyzic acid of Porrett. Dissolve in water one part of sulphuret of potassa, and boil it for a considerable time with three or four parts of powdered Prussian blue added at intervals. Sulphuret of iron is formed, and a colorless liquid containing the new acid combined with potassa, mixed with hyposulphate and sulphate of potassa. Render this liquid sensibly sour, by the addition of sulphuric acid. Continue the boiling for a little, and, when it cools, add a little peroxide of manganese in fine powder, which will give the liquid a fine crimson color. To the filtered liquid add a solution containing persulphate of copper, and protosulphate of iron, in the proportion of two of the former salt to three of the latter, until the crimson color disappears. Sulphuroprussiate of copper falls. Boil this with a solution of potassa, which will separate the copper. Distil the liquid mixed with sulphuric acid in a glass retort, and the peculiar acid will come over. By saturation with carbonate of barytes, and then throwing down this by the equivalent quantity of sulphuric acid, the sulphuroprussic acid is obtained pure. It is a transparent and colorless liquid, possessing a strong odor, somewhat resembling acetic acid. Its specific gravity is only 1.022. It dissolves a little sulphur at a boiling heat. It then blackens nitrate of silver; but the pure acid throws down the silver white. By repeated distillations sulphur is separated and the acid is decomposed.

SULPHUROUS. See **SULPHUREOUS.** Sulphurous is preferred to sulphureous by many modern chemists.

SULPHUROUS ACID. Sulphur burned at a low temperature absorbs less oxygen than it does when exposed to greater heat, and is consequently acidified in a slighter degree, so as to form sulphurous acid. This in the ordinary state of the atmosphere is a gas; but on reducing its temperature very low by artificial cold, and exposing it to strong compression, it becomes a liquid. To obtain it in the liquid state, however, for practical purposes, it is received into water, by which it is absorbed.

As the acid obtained by burning sulphur in this way is commonly mixed with more or less sulphuric acid, when sulphurous acid is wanted, it is commonly made by abstracting part of the oxygen from sulphuric acid by means of some combustible substance. Mercury or tin is usually preferred. For the purposes of manufactures, however, chopped straw or saw dust may be employed. If one part of mercury and two of concentrated sulphuric acid be put into a glass retort with a long neck, and heat applied till an effervescence is produced, the sulphurous acid will arise in the form of gas, and may be collected over quicksilver, or received into water which at the temperature of 61° will absorb thirty-three times its bulk, or nearly an eleventh of its weight. Water thus saturated is intensely acid to the taste, and has the smell of sulphur burning slowly. It destroys most vegetable colors, but the blues are reddened by it previous to their being discharged. A pleasing instance of its effect on colors may be exhibited by holding a red rose over the blue flame of a common match, by which the color will be discharged wherever the sulphurous acid comes into contact with it, so as to render it beautifully variegated, or entirely white. If it be then dipped into water, the redness after a time will be restored.

Sulphurous acid is used in bleaching, particularly for silks. It likewise discharges vegetable stains, and iron-moulds from linen. In combination with the salifiable bases, it forms sulphites, which differ from the sulphates in their properties. The alkaline sulphites are more soluble than the sulphates, the earthy less. They are converted into sulphates by an addition of oxygen, which they acquire even by exposure to the air.

SULPICIA, or Sulpitia, an ancient Roman poetess, who lived under the reign of Domitian, and has been so much admired as to be termed the Roman Sappho. We have nothing, however, left of her writings but a satire, or rather the fragment of one, against Domitian, who published a decree for the banishment of philosophers from Rome: which satire is to be found in Scaliger's Appendix Virgiliana. She is mentioned by Martial and Sidonius Appollinaris; and is said to have addressed a poem on conjugal love to her husband Calenus, a Roman knight.—Mart. Ep. 35.

SULPICIUS SEVERUS. See SEVERUS. He was contemporary with Rufinus and St. Jerome; the disciple of St. Martin of Tours, whose life he has written; and the friend of Paulinus bishop of Nola, with whom he held an intimate correspondence. The style of his *Historia Sacra* is elegant beyond the age he lived in.

SULTAN, n. s. Arab. *soltan*. The Turkish emperor.

By this scimitar,
That won three fields of *sultan* Solyman.

Shakspeare.

I affirm the same of the *sultanry* of the Mamalukes, where slaves bought for money, and of unknown descent, reigned over families of freemen.

Bacon.

Turn the *sultana's* chambermaid. *Cleveland.*
Lay the towering *sultanes* aside. *Irene.*

SULTAN, or SOLDAN, is said by Vattier to be a Turkish word, and to signify king of kings; adding that it was first given to the Turkish princes Angrolipex and Masgud, about A. D. 1055; others will have it originally Persian, alleging, in proof hereof, an ancient medal of Cosroes; others derive it from soldanus, quasi solus dominus: others from the Hebrew שולט, shalet or sheleth, to rule. It had its rise under Mahmoud, son of Sebeceteghin, the first emperor of the dynasty of the Gaznevites, towards the close of the fourth century of the era of the Hegira: when that prince going to Segestan to reduce Kalaf, governor of that province, who affected the sovereignty, Kalaf was no sooner advertised of his coming than he went out to meet him, delivered the keys of his fortress, and owned him his sultan, that is, his lord or commander. The title pleased Mahmoud so well that he assumed it ever afterwards; and from him it passed to his descendants, and to other Mahometan princes. It is chiefly confined to the Turkish and Persian monarchs.

SULTANIA, an ancient and considerable town of Persia, in Irac, built in the thirteenth century, on the ruins of the ancient Tigranocerta. It was often a royal residence, and was once one of the largest cities of Asia. It was taken and pillaged by Tamerlane; but he spared the edifices dedicated to religion. It has a magnificent mosque, and is fifty miles north-west of Casbin, and 225 or 250 N. N. W. of Ispahan.

SULTRY, adj. Imagined by Skinner to be corrupted from sulphury, or sweltry. But Sax. *sol*, like Lat. *sol*, is both heat and sun. Hot without ventilation; hot and close.

The *sultry* breath
Of tainted air had cloyed the jaws of death.

Sandys.

It is very *sultry* and hot. *Shakspeare. Hamlet.*
Such as, born beneath the burning sky
And *sultry* sun, betwixt the tropicks lie.

Dryden's Æneid.

Our foe advances on us,
And envies us even Lybia's *sultry* desarts.

Addison's Cato.

Then would *sultry* heats and a burning air have scorched and chapped the earth, and galled the animal tribes in houses or dens.

Cheyne.

SULZER (John George), a celebrated philosopher, born at Winterthun, in Zurich, October 16th, 1720. He was the youngest of twenty-five children. His early education did not promise much, though it was by no means neglected. He made but a small progress in the learned languages, to prepare him for theology, for which his parents designed him. At sixteen, when he went to the academical school of Zurich, he had no notion of the sciences, nor any taste for study. The first incident that developed a hidden germ.

of philosophical genius was his meeting with Wolfe's *Metaphysics*: this excited his taste for science; but he wanted a guide. The clergyman with whom he lodged was ignorant; and the academical prelections were as yet above the reach of his comprehension. On the other hand a sociable turn of mind led him often into company, where he lost much time in frivolous amusements, yet without corrupting his morals. The learned Gesner rendered Sulzer's inclination to study triumphant over his passion for amusement. Animated by the counsels and example of this worthy man, he applied himself to philosophy and mathematics with great ardor, and resumed the pursuit of Grecian literature and the Oriental languages. The contemplation of nature became his favorite passion. An ecclesiastical settlement in a rural scene that exhibited happy objects and occasions for this delightful study began to render his days happy and useful; and he published in 1741 *Moral Contemplations of the Works of Nature*; and in 1742 an account of a journey he had made through the Alps; which showed his knowledge of natural history, and the sensibility with which he surveyed the beauties of nature, and the grandeur and goodness of its Author. He afterwards became private tutor to a young gentleman at Magdeburg. This procured him the acquaintance of Messrs. Maupertuis, Euler, and Sack, which opened to him merit the path of preferment, and advanced him successively to the place of mathematical professor in the King's College at Berlin in 1747, and to that of member of the Royal Academy in 1750. In this last quality he distinguished himself in a very eminent manner, enriched the class of speculative philosophy with a great number of excellent memoirs, and was justly considered as one of the first-rate metaphysicians in Germany. But his genius was not confined to this branch of science. His *Universal Theory of the Fine Arts* is a valuable production. A profound knowledge of the arts and sciences, and a perfect acquaintance with true taste, are eminently displayed in this work. The first volume was published in 1771, and the second in 1774. His *Remarks on the Philosophical Essays of the late Mr. Hume* is a work of real merit, which does justice to the acuteness, while it often detects the sophistry, of the British Bayle. The moral character of M. Sulzer was amiable and virtuous; and his virtues were animated by that sacred philosophy that forms the Christian, ennobles man, and is the only source of that heart-felt serenity and sedate fortitude which support humanity when every other object of confidence fails. His dying moments were calm, humble, and sublime. He had no enemy; and his friends were numerous, affectionate, and worthy of the tender returns he made them. Frederick the Great of Prussia distinguished him by repeated marks of munificence and favor, though he had never seen him before 1777. Sulzer died in 1779.

SUM, *n. s. & v. a.* } *Lat. summa*; *Fr. somme*.

SUM'LESS, *adj.* } The whole; many particulars aggregated; compendium; amount; height; completion; abridgment: to compute; comprise; comprehend: in falconry, to have full grown plumage: the adjective corresponds.

The high priest may *sum* the silver brought in.

2 Kings xxii.

How precious are thy thoughts unto me, O God! how great is the *sum* of them! *Psalm cxxxix. 17.*

We may as well conclude so of every sentence, as of the whole *sum* and body thereof.

Hooker.

This, in effect, is the *sum* and substance of that which they bring by way of opposition against those orders which we have common with the church of Rome.

Id.

You cast the' event of war,
And *summed* the' account of war.

Shakspeare. Henry IV.

I did send to you

For certain *sums* of gold, which you denied me.

Shakspeare.

Make his chronicle as rich with prize,
As is the ouzy bottom of the sea
With sunken wreck and *sumless* treasures.

Id. Henry V.

In sickness, time will seem longer without a clock than with it; for the mind doth value every moment, and then the hour doth rather *sum* up the moments than divide the day.

Bacon.

This having learned, thou hast attained the *sum*
Of wisdom.

Milton.

So lovely fair!

That what seemed fair in all the world, seemed now Mean, or in her *summed* up, in her contained.

Id.

With prosperous wing full *summed*.

Id.

A *sumless* journey of incorporeal speed.

Id.

To conclude, by *summing* up what I would say concerning what I have, and what I have not been; in the following paper I shall not deny that I pretended not to write an accurate treatise of colours, but an occasional essay.

Boyle.

I appeal to the readers, whether the *sum* of what I have said be not this.

Tillotson.

SUMATRA, a large island in the eastern seas, obliquely divided by the equator into almost equal parts, is situated the most to the west of all the Sunda chain. Its northern point stretches into the Bay of Bengal; its south-west coast is exposed to the great Indian Ocean; towards the south-east it is separated by the Straits of Sunda from the island of Java; on the east by the China and Eastern Seas from Borneo and other islands; and on the north-east by the straits of Malacca from the Malay Peninsula. In length it may be estimated at 1050 miles, by 165 miles the average breadth. Among the eastern people generally, and the better informed of the natives, this island is known by the names of Pulo Puri-chu and Indalas; the origin of the name Sumatra is uncertain. By Marco Polo it is called Java Minor.

A chain of mountains runs through its whole extent, the range being in some parts double and triple; but, in general, much nearer the western than the eastern shore. Its distance from the sea on the former side is seldom more than twenty miles, but on the latter a level country intervenes of at least 150 miles in the broadest part. The height of these mountains is not sufficient to cause them to be covered with snow during any part of the year. The highest point visible from the sea is Mount Ophir, which is situated nearly under the equator, and is stated by Marsden to be 13,842 feet high. Many other points are also very elevated, and the summit of a volcano, south of Mount Ophir, is said,

by the same writer, to be 12,465 feet above the sea. Between these ridges there are extensive plains of considerable height, which render the air cool, and make them the most desirable parts of the island. They are consequently the best peopled, and the most cleared from woods, which, in other parts, cover both hill and valley with perpetual shade. Many large and beautiful lakes are interspersed amid these mountains, which greatly facilitate the intercourse between the adjacent districts. These are represented as of great extent, but of uncertain situation, as the accounts are merely derived from the natives, who have not the means of correctly determining their positions. One in the Lampon country, towards the southern extremity of the island, is navigated by large boats with sails, and is said to require a day and a night to cross it; but it is not said at what season. Few parts of the world, indeed, are better supplied with water. Numerous streams descend from the interior to the coasts, and water the intervening regions. From the proximity of the elevated tracts, those on the west are too small and rapid for the purposes of navigation, but those on the opposite side of the island, flowing through a much wider space, accumulate a great number of subsidiary streams, and acquire a more equable and gentle current before they reach the sea. They are therefore navigable for many miles from the coast; but the entrance of most of them is impeded by sand banks thrown up by the violent surf that continually beats against the shore. The same cause also compels many of them to run nearly parallel to the coast before they mingle their waters with the sea.

As to the *climate* of this island, Mr. Marsden observes, 'The heat of the air is by no means so intense as might be expected, in a country occupying the middle of the torrid zone. It is more temperate than in many regions within the tropics, the thermometer at the most sultry hour, which is about two in the afternoon, generally fluctuating between 82° and 85°. I do not recollect to have ever seen it higher than 86° in the shade, at Fort Marlborough; although at Natal, in lat. 24° N., it is not unfrequently at 87° and 88°. At sun-rise it is usually as low as 70°; the sensation of cold, however, is much greater than this would seem to indicate, as it occasions shivering and a chattering of the teeth; doubtless from the great relaxation of the body and openness of the pores in that climate; for the same temperature in England would be esteemed a considerable degree of warmth. These observations on the state of the air apply only to the districts near the sea coast, where, from their comparatively low situation, and the greater compression of the atmosphere, the sun's rays operate more powerfully. Inland as the country ascends, the degree of heat decreases rapidly, insomuch that, beyond the first range of hills, the inhabitants find it expedient to light fires in the morning, and continue them till the day is advanced, for the purpose of warming themselves; a practice unknown in other parts of the island; and in the journal of lieutenant Dare's expedition it appears that, during one night's halt on the summit of a mountain, in the rainy season, he lost several of his

party from the severity of the weather, whilst the thermometer was not lower than 40°. The atmosphere is in common more cloudy than in Europe, which is sensibly perceived, from the unfrequency of clear star-light nights. This may proceed from the great rarefaction of the air occasioning the clouds to descend lower, and become more opaque, or merely from the stronger heat exhaling from the land and sea a thicker and more plentiful vapor. The fog, called *kabut* by the natives, which is observed to rise every morning among the distant hills, is dense to a surprising degree; the extremities of it, even when near at hand, being perfectly defined; and it is seldom observed to disperse till about three hours after sun-rise. Thunder and lightning are so common here that they scarcely attract the attention of persons who have been long resident; but during the north-west monsoon the explosions are extremely violent. The sky frequently seems on fire, and the agitation of the ground resembles a slight earthquake. In the opposite monsoon the lightning is more constant, but the coruscations are less vivid, and the thunder more feeble. Some variation takes place in the monsoon in the different parts of the archipelago, as well as on the opposite coasts of the Indian peninsula. On the west side of Sumatra, and south of the equator, the south-east monsoon, or dry season, commences in May, and declines in September. The wind sets in from the opposite quarter in November, and the heavy rains cease in March. Variable wind and weather occupy the intermediate periods. In both this and the other countries within the tropics, the land and sea breezes alternately prevail, and contribute greatly towards mitigating the intensity of the solar rays.

The *soil* is in general a black mould upon a substratum of red clay, which produces an exuberance of vegetation; and what would be one of the most productive countries on the globe, if properly cultivated, naturally becomes an impervious forest. Rice is the staple product of agriculture, and the crops are often very abundant. According to the historian of Sumatra the return is frequently a hundred-fold. Nearly all the vegetables and animals of the torrid zone are to be found in this island, which also abounds in minerals and fossil treasures. It has in all ages been noted for its gold, besides which there are copper, iron, tin, and sulphur, saltpetre, and coals, with other fossils. Petrifications, and all the substances ejected by volcanoes, are also met with, and coral reefs are formed in many places off the coast. The English settlement at Bencoolen, or Fort Marlborough, is near the western shore, in 3° of S. lat. Belonging to the residency at Bencoolen are a number of districts chiefly inhabited by the tribe of Sumatrans called Rejang, who are a peaceable and inoffensive race. These tracts are devoted to the growth of pepper, of which they yield about 1000 tons annually. The culture of the clove and nutmeg has also been introduced.

Acheen, or Achin, the most celebrated native kingdom of the island, occupies the north-west extremity of the island. See ACHEEN. It is the only one whose political importance has been thought sufficient to render its transactions the

subject of general history. Acheen the capital is situated on a plain near the banks of a river, about a league from the sea.

Among the *productions* of Sumatra which are regarded as articles of commerce, the most abundant, and formerly the most important, was pepper, of which the East India Company used to export large quantities, but it is now reduced to one solitary cargo annually of the value of about £15,000. The white pepper is made by bleaching the grains of the common sort, by which it is deprived of its exterior pellicle. This article takes little damage by submersion in sea water. On the capture of the Moluccas, in 1796, nutmeg and clove plants were introduced, and have since rapidly increased. There are now, according to major Hamilton, above 20,000 nutmeg trees in full bearing, capable of yielding annually 200,000 lbs. and 56,000 lbs. of mace. Among the most valuable productions of the island is camphor, for which Sumatra and Borneo have been celebrated from the earliest times. The tree is sometimes fifteen feet in circumference, the camphor being found in a concrete state in the natural fissures and crevices of the wood. The natives cut down a great many trees at random before they find one that contains a sufficient quantity to repay their labor, although always assisted in their research by a professional conjurer, whose skill must be chiefly employed in concealing or accounting for his own mistakes. The whole quantity brought for sale rarely exceeds fifty peculs (133½ lbs. each). The trade is chiefly in the hands of the Acheenese, who buy the article from the Batta people, and dispose of it to the Europeans and Chinese. The Japan camphor is of a very inferior quality.

Benzoin, or benjamin, is found almost exclusively in the Batta country. The best is sent to Europe, and the inferior sort is exported to Arabia, Persia, and some parts of Hindostan, where it is burned to perfume their temples and private houses. From England it is re-exported to the Roman Catholic and Mahometan countries, to be used as incense. It is also employed in medicine as a styptic. Cassia is also produced and exported, and rattans furnish annually many cargoes. The annual and the shrub cotton are cultivated by the natives, but only in sufficient quantities to supply their own wants. The silk cotton is a most beautiful raw material, but owing to the shortness and brittleness of the staple is unfit for the reel and the loom, and is only applied to the unworthy purposes of stuffing pillows and mattresses. The coffee tree is universally planted, but the berry is not of a good quality, probably owing to the want of skill in the management. Among the other articles of commerce are danimer, a species of turpentine or resin; dragons' blood, a drug obtained from a large species of rattan; gambir, a juice extracted from the leaves of a plant of the same name. Lignum aloes, or agila wood, highly prized in the east for its fragrant scent while burning.

The forests contain an inexhaustible store and endless variety of timber trees, many sorts of which are capable of being applied to ship-

building; but the teak does not appear to be indigenous to the island, although it flourishes to the northward and southward, in Pegu and Java. The other remarkable trees are the poon, so named from a Malay word, which signifies wood in general, and is preferred for masts and spars. The camphor wood is used for carpenters' purposes. The iron wood so named on account of its hardness. The marbau, used as beams for ships and houses. The pinaga, valuable as crooked timber from frames and knees. The ebony; the kayu gadis, a wood possessing the flavor and qualities of sassafras; the rangi, supposed to be the manchineel tree of the West Indies, has a resemblance to mahogany. Of the various sorts of trees producing dammer, some are also valuable as timber, and here also is found the spreading banyan tree of Hindostan.

In the central parts of the island gold is procured, and Menancabow has always been esteemed the richest in this metal. In the districts inland from Padang, which is the principal mart, it is collected from mines, and from the channels of rivers; pieces of gold have also occasionally been found, weighing nine ounces and upwards. Probably only one-half of all the gold procured reaches the hands of Europeans; yet it is asserted, on good authority, that from 10,000 to 12,000 ounces have been annually received at Padang alone, at Nalaboo 2000, at Natal 800, and at Mocomoco 600. The merchants carry the gold from the interior to the sea coast, where they barter it for iron and iron working tools, opium, and the fine piece goods of Madras and Bengal. When bought at the settlements, it used formerly to be purchased at the rate of £3 5s. per ounce, but afterwards rose to £3 18s., which would yield no profit on exportation to Europe. In many parts of the country it is employed instead of coin, every man carrying a small pair of scales about with him. At Acheen small thin gold coins were formerly struck, but the coinage has been abandoned in modern times. Silver is not known as a production of Sumatra. Tin is a considerable article of trade, the mines of which are situated on the island of Banca. Iron ore is dug on Sumatra, but not in large quantities, the consumption of the natives being supplied with English and Swedish bar iron. Sulphur is procured from the volcanoes, and yellow arsenic is an article of traffic. In the country of Kuttaun are extensive caves, from the soil of which saltpetre is extracted; and from similar caverns the edible bird nests are procured for the China market, where also the biche de mer is sent, and is there employed as a seasoning. At Batavia the last article sells for forty-five dollars per pecul of 133½ lbs. The other exports are bees' wax, gum lac, and ivory. Elephants were formerly exported from Acheen to the Coromandel coast, in vessels built on purpose, but this trade has long declined.

The most general articles of import, says Mr. Hamilton, are the following. From the coast of Coromandel various cotton goods, such as long cloth, blue and white chintzes, colored handkerchiefs, and also salt. From Bengal muslins, striped and plain; and several kinds of cotton

goods, as baftaes, cossaes, hummums, &c., taf-fetas and some other silks, and opium in considerable quantities. From the western coast of India various cotton goods, mostly of a coarse fabric. From China coarse porcelain, iron pans in sets of different sizes, tobacco shred very fine, gold threads, fans, and a number of small articles. From Celebes (known here by the name of its chief provinces, Macassar, Buggess, and Mandar), Java, Bally, Ceram, and other eastern islands, the rough striped cotton cloth, commonly called Buggess clouting, the universal body dress of the natives; creeses, and other weapons; silken creese belts, tudongs, or hats, small pieces of ordnance, commonly of brass, called rantaka, spices, salt of a large grain, and sometimes rice, chiefly from Bali. From Europe are imported silver, iron, steel, lead, cutlery, various sorts of hardware, brass wire, and broad cloths, especially scarlet.

The beautiful gold and silver filagree work of Sumatra has long been celebrated and admired, and is a matter of still greater curiosity from the extreme coarseness of the tools employed in the manufacture. From a piece of old iron hoop the wire drawing instrument is made, a hammer head stuck in a block serves for an anvil; and a pair of compasses is seen composed of two old nails tied together at one end. The gold is fused in a piece of a rice pot; in general they use no bellows, but blow the fire with their mouths through a joint of bamboo. If the quantity of gold to be melted be considerable, three or four persons sit around their furnace, which is an old iron pot, and blow altogether. But little skill is shown by the natives in forging iron. They make nails, although seldom used in building. They are ignorant of the use of the saw, except where it has been introduced by the Europeans. Painting and drawing they are strangers to; in carving they are fanciful, and their designs grotesque, and always out of nature. Silk and cotton cloths manufactured by themselves are worn by the natives in all parts of the country. Their looms and weaving apparatus are extremely defective. They manufacture different kinds of earthenware of a coarse fabric; and extract the cocoa nut oil, which is in general use. Gunpowder is manufactured in various parts of the island, but less in the southern provinces than among the people of Menacabow, the Battas, and the Acheenese, whose frequent wars demand large supplies. The powder is very imperfectly granulated, being often hastily prepared in small quantities for immediate use. Salt is mostly supplied by cargoes imported, but they also manufacture it themselves by a very tedious process.

Among the modern political divisions of the island, the principal are the empire of Menacabow and the Malays; in the next place, the Acheenese; then the Battas, the Rejangs, and next to them the people of Lampong. The chain of islands which extends in a line nearly parallel to the western coast, at the distance of little more than a degree, are inhabited by a race, or races of people, apparently from the same original stock as those of the interior of Sumatra. Their genuineness of character has been preserved to a

remarkable degree, whilst the islands on the eastern side are uniformly peopled with Malays. Until about 100 years ago the southern coast of Sumatra, as far as the Urei River, was dependent on the king of Bantam in Java, whose lieutenant came yearly to Bencoolen, or Sillebar, to collect pepper, and fill up the vacancies. Almost all the forms of government throughout Sumatra are a mixture of the feudal and patriarchal; but the system of government among the people near the sea coast is much influenced by the power of the Europeans. The districts over which the East India Company's influence extends are preserved in a state of uninterrupted peace, and, were it not for this coercion, every village would be in a state of perpetual hostility with its neighbour. The form of government among the Rejangs applies generally to the Orang ulu, or inhabitants of the interior. Among the hills and woods property in land depends upon occupancy, unless where fruit trees have been planted; and, as there is seldom any determined boundary between neighbouring villages, such marks are rarely disturbed.

The Sumatran laws are properly a set of long established customs handed down to them from their ancestors, the authority for which is founded in usage and general consent. The law which renders all the members of a family reciprocally bound for each other's debts, forms a strong connexion among them. When a man dies, his effects descend to his children in equal shares. The Sumatran code admits of a pecuniary compensation for murder, on which account their laws take no cognisance of the distinction between a wilful murder and what we term manslaughter. Corporeal punishment of any kind is rare. The place of the greatest solemnity for administering an oath is the burying ground of their ancestors; and they have certain reliques, or swearing apparatus, which they produce on important occasions. These generally consist of an old broken creese, a broken gun barrel, some copper bullets, or any thing else to which chance or caprice has annexed the idea of extraordinary virtue. These they generally dip in water, which the person who swears drinks off, after pronouncing a form of words. At Manna the relique most venerated is a gun barrel, which, when produced to be sworn on, is carried to the spot wrapt up in silk, and under an umbrella. The Sumatran impressed with the idea of invisible powers, but not of his own immortality, regards with awe the supposed instruments of their agency, and swears on creeses, bullets, and gun barrels, weapons of personal destruction.

Slavery is established in this island, as it is universally throughout the east; yet but few instances occur of the country people actually having slaves, although they are common in the Malayan or sea-port towns. At Bencoolen the East India Company have a body of negro slaves. These hold the natives of the island in great contempt, have an antipathy to them, and enjoy any occasion of doing them mischief; the Sumatrans, on the other hand, consider the negroes merely as devils half humanized.

The *inhabitants* are rather below the middle size; their limbs are, for the most part, slight,

but well shaped, and are particularly small at the wrists and ancles. The women follow the preposterous custom of flattening the noses and compressing the skulls of children newly born, and also pull out the ears of the infants to make them stand at an angle with the head. The males destroy their beards, and keep their cliins remarkably smooth. Their complexion is properly yellow, wanting the red tinge that constitutes a tawny or copper color. The females of the upper classes, not exposed to the rays of the sun, approach to a degree of fairness. Persons of superior rank encourage the growth of their hand nails to an extraordinary length; the hands of the natives generally, and even those of the half breed, are always cold. The inland natives are superior in size and strength to the Malays on the coast, and possess also fairer complexions. Among the hills the inhabitants are subject to monstrous wens, or goitres on the throat. Both sexes have the extraordinary custom of filing and disfiguring their teeth, which are naturally very white and beautiful, from the simplicity of their food. Many, particularly the women of the Lampong country, have their teeth rubbed down even with their gums; others have them formed into points, while some file off no more than the outer extremities, and then blacken them with the empyreumatic oil of the cocoa nut shell. The great men set their teeth in gold, by casing with a plate of that metal the under row; which ornament, contrasted with the black dye, has by candle light a very splendid effect. It is sometimes indented to the shape of their teeth, but more usually is quite plain, and it is not removed either to sleep or eat. The original clothing of the Sumatrans is the same with that found by navigators among the South Sea Islands, and in Europe generally called Otahaitan cloth. It is still used among the Rejangs as their working dress, but the country people now conform to the costume of the Malays.

The dusuns, or villages for the inhabitants, are so few that they are not entitled to the name of towns, are always situated on the banks of a river or lake, for the convenience of bathing and of transporting goods. Their buildings are of wood and bamboos, covered with palm leaves. The frames of the houses rest on stout wooden pillars, about six or eight feet in height, and are ascended to by a piece of stout bamboo cut into notches. Detached buildings in the country are raised ten or twelve feet from the ground, as security against tigers. The furniture is extremely simple, and neither knives nor forks are required, as in eating they take up the rice and other victuals between the thumb and fingers, and throw it into the mouth by the action of the thumb. The art of medicine here consists almost entirely in the application of simples. Every old man and woman is a physician, and their rewards depend on their success, but they generally procure a small sum in advance, under the pretext of purchasing charms. In fevers, during the paroxysm, they pour over the patient a quantity of very cold water, which afterwards brings on a copious perspiration. The venereal disease, although common in the Malay bazars, is little known in the interior.

On the sea-coast the Malay language is intermixed with the Batta and other original languages. The Malays fix the length of the year at 354 days, or twelve lunar months of twenty-nine days and a half each; the original Sumatrans count their years from the number of their crops of grain. They are fond of music, and have many instruments, mostly borrowed from the Chinese. The Malays of Sumatra use the Arabic character, and have incorporated a great many Arabic, and also Portuguese words, in their language. The other principal languages of Sumatra are the Batta, the Rejang, and the Lampong; the difference between them being chiefly marked by their being expressed in distinct written characters. They write on the inner bark of a tree, and on bamboos, and form their lines from their left hand towards the right. The native Sumatran of the interior differs in some respects from the Malay of the coast, being mild, peaceable, and forbearing, unless when roused by violent provocation. He is temperate and sober, his diet being mostly vegetable, and his only beverage water. Their hospitality is very great with very simple manners; and they are in general, except among the chiefs, devoid of the Malay cunning and chicane. On the other hand they are litigious, indolent, and addicted to gaming, dishonest in their dealings with strangers, which they consider as no moral defect, regardless of truth, mean, servile; and, though cleanly in their persons, filthy in their apparel, which they never wash. They are careless and improvident of the future, and make no advances in improving their condition. The Macassars and Bugesses, who come annually from Celebes in their prows to trade at Sumatra, are looked up to by the Sumatrans and Malays as their superiors in manners. They also derive part of the respect paid to them from the richness of their cargoes, and the spirit with which they spend the produce in gaming, cock fighting, and smoking opium. Through every rank of the people there prevails a strong propensity to gaming, and to cock-fighting they are still more passionately addicted. The artificial spur used resembles the blade of a scimitar, and proves a more destructive weapon than the European spur. The Malay breed of cocks are much esteemed by connoisseurs who have had an opportunity of trying them. In some places they match quails in the manner of cocks, which fight with great inveteracy, and endeavour to seize each other by the tongue.

The Sumatrans generally, but more particularly the Malays, are much addicted to the custom of smoking opium. The poppy which produces it not growing on the island, it is annually imported from Bengal in considerable quantities, in chests of 140 lbs. each, and on the west coast about 20,000 lbs. are used annually. It is mixed up with tobacco into the form of pills about the size of a pea, which quantity is consumed at one whiff. The smoke is never emitted by the mouth, but usually receives vent through the nostrils, and sometimes by adepts through the passages of the ears and eyes. Although so much opium is smoked in this island, the practice of running a muck (called by the natives mangamok) is by no means fre-

quent. It is remarkable that at Batavia, where the criminals are broken on the wheel with every aggravation of cruelty, mucks or deadly affrays often occur; while at Bencoolen, where they are executed in the easiest manner, the offence is extremely rare. On the west coast the Malays have been so long accustomed to the mild government of the British, that their manners and habits are considerably improved; while on the east coast they continue ferocious, sanguinary, and treacherous. The original Sumatran vessel for boiling rice, and which is still used for that purpose, is a joint of green bamboo. By the time the rice is dressed, the utensil is nearly destroyed by the fire; but it resists the flame so long as there is no moisture within. Although the natives subsist in a great measure on vegetable food, they are not restrained by any prejudice of caste from other aliments; and accordingly, at their entertainments, the flesh of the buffalo, the goat, and fowls, are served up. Their dishes are almost all dressed as curries, and their flesh meat is cooked immediately after it is killed, which is still warm. Sago, although common, is not in such general use as among the more eastern islands, where it is employed as a substitute for rice. When these articles of subsistence fail, the Sumatran finds others in the woods; hence famines in the island are never attended with any very destructive consequences.

The natives are in general good speakers, the gift of oratory seeming natural to them. A Sumatran ever scrupulously abstains from pronouncing his own name, not from any motive of superstition, but merely as a punctilio in manners: and it occasions him infinite embarrassment when a stranger, unacquainted with their customs, requires it of him. As soon as he recovers from his confusion, he solicits the interposition of his neighbour. They can seldom give an accurate account of their age; but, so far as can be inferred from observation, not a great proportion of the men attain the age of fifty, and sixty is accounted a long life.

If by *religion* is meant a public or private form of worship of any kind, and of prayers, processions, meetings; offerings, images, or priests, are all or any of them necessary to constitute it; the Rejangs, that race of Sumatrans with which we are most acquainted, are totally without religion, and cannot with propriety be even termed pagans, if that phrase is understood to convey the idea of mistaken worship. They neither worship God, devil, nor idol. They are not, however, without superstitious beliefs of many kinds; and have a confused notion, though perhaps derived from their intercourse with other people, of some superior beings, who have the power of rendering themselves visible and invisible at pleasure. These they call *orang alus*, fine or impalpable beings, and regard them as possessing the faculty of doing them good or evil. They also call them *maleikat* and *jin*, which are the angels and evil spirits of the Arabians, and the idea was probably borrowed at the same time with the name. They have no word in their language to express the person of God except the '*Allah tala*' of the Malays, corrupted by them to '*Ulah talo*.' The Sumatrans, where

untinctured with Mahometanism, do not appear to have any notion of a future state. Where Mahometanism prevails boys are circumcised between the sixth and tenth year.

The superstition which has the strongest influence on their minds, and which approaches the nearest to a species of religion, is that which leads them to venerate, almost to the point of worshipping, the tombs and manes of their deceased ancestors. They have an imperfect notion of a metempsychosis, but not in any degree systematic, nor considered as an article of religious faith. They seem to think in general that tigers are actuated by the spirits of deceased men, and speak of them with a degree of awe. They relate stories also of a place in the interior country, where the tigers have a court, and maintain a regular form of government, and have their houses thatched with women's hair. The Sumatrans are also firmly persuaded, that various particular persons are what they term *betuah* (sacred impassive, invulnerable and not liable to accident); and this quality they extend to things inanimate, such as ships and boats.

Few attempts have ever been made by missionaries, or others, to convert the inhabitants of this island to Christianity. Of the many thousands baptised in the Eastern Isles by the celebrated Francis Xavier, in the sixteenth century, not one of their descendants are now found to retain a ray of the light imparted to them. As it was novelty only, and not conviction, that induced the original converts to embrace a new faith, the impression lasted no longer than the sentiment which recommended it, and disappeared as rapidly as the missionary. Under the influence, however, of the Spanish government at Manila, and of the Dutch at Batavia, there are many native Christians educated as such from their childhood. The neglect of missions to Sumatra is one of the causes that the interior of the country is so little known. From various sources of information, sufficiently distinct from each other, the conclusion may be drawn, that the Mahometan religion had not made any considerable progress in the interior of Sumatra earlier than the fourteenth century. The province of Menacabow, although situated inland, is by far the most completely converted, the inhabitants being wholly Mahometans. Perhaps it is less surprising that this one kingdom should have been completely converted than that so many districts should remain to this day without any religion whatever. Every thing conspires to induce the Sumatran to embrace a system of belief, and scheme of instruction, in which there is nothing repugnant to prejudices already imbibed; he relinquishes no favorite ancient worship to adopt a new, and is manifestly a gainer by the exchange.

SUMBHAWA, a large island of the eastern seas, situated between 8° and 9° S. lat., separated from Lombhook by the Straits of Allass; in length it may be estimated at 180 miles, by forty the average breadth. It is deeply indented near the middle, by an extensive bay, which almost divides it into two portions.

This island contains the petty states of Bima, Dampo, Tambora, Sangar, Papikat, and Sumb-

hawa. Their chiefs were either the allies of, or under the protection of the Dutch East India Company; and were all sufficiently obedient, except the last, which was refractory, being instigated thereto by the Macassars and Wadjorese of Celebes, who resort in great numbers to this island, especially the latter. Country ships here procure articles of trade for the China market; and, in 1778, sapan wood to the amount of 580,000 lbs. weight was exported from this island, and sold in Holland. The Dutch trade to Sumbhawa was under the superintendance of the Macassar residency.

Bima is at the east end of Sumbhawa, and comprehends under its jurisdiction the Straits of Sapy, the whole of Manjeray, and the island of Goonong Api. The Bima language extends over the east part of Sumbhawa, and the western portion of the Island of Ende, denominated Floris by the early Portuguese navigators. The dialect of Sumbhawa, which prevails in the districts not subject to the sultan of Bima, is of a more mixed character than that of Bima. Neither the latter, nor the Sumbhawa, have any peculiar character, but use indifferently the Buggess or Malay characters. Stavorus and Notes, Leyden, Hamilton.

SUMBHOONAUTH, a town and temple in the Ghoorkhali territories, in Nepal, in lat. 27° 33' N., long. 85° 38' E. The temple is a very ancient edifice, having been erected when Nepal was subject to the Tibet race, who, having been expelled by the Newars, obtained the name of Khat Bhootas (or Bhootas of Catmandoo), which they preserve: at present they occupy the Kutchar mountains. The possession of the temple is claimed by the Delai lama (the sovereign pontiff of Lehassa), as a dependency on his spirituality. Upon the rupture which took place some years ago between the Tibetians and Nepal, the lama's vicar was obliged to evacuate the sanctuary, which was afterwards held on the part of the Deb rajah of Bootan. The temple principally visited by the Bootias and Bahauras is on the terrace of a hill, and is distinguished at a great distance by its spires covered with plates of copper, highly gilt. It is chiefly celebrated for its perpetual fire, the priests asserting that the flame of the two largest lamp wicks have been preserved from time immemorial.

SUMBHULPOOR, or SAMBHALPURA, a town and district in the province of Gundwana, situated between the twenty-first and twenty-second parallels of N. lat. This territory takes its name from the capital, but the rajah is styled Rajah Autaraghur, or the rajah of eighteen forts. It is bounded on the west by the district of Ruttunpoor and Boora Shumbur; to the east by Bimbera, Landaoli, and Boad; to the south by Patna and Coondon; and on the north by Gangpoor and Sirgoajah. The air is very unwholesome, owing to the quantity of jungle. The soil in the valleys is a rich loam, in which grain or pulse thrive; and in the mountains gold and diamonds are found. The natives, in washing the sand of the rills that descend from them, procure considerable quantities of gold. The diamonds are found about thirteen miles beyond Sumbhulpoor, near the junction of the Hebe

with the Mahanuddy. At this place, after the rains, the natives find the diamonds in the red earth of the river Hebe. The matrix is a clay, which appears burned red, nearly to the degree bricks usually are.

SUM'MARILY, *adj.* & *n. s.* } Fr. *sommaire*; or
SUM'MARILY, *adv.* } from Sun. Short;
brief; compendious: a compendium or abstract:
the adverb corresponding.

The decalogue of Moses declareth *summarily* those things which we ought to do; the prayer of our Lord, whatsoever we should request or desire.

Hooker.

We are enforced from our most quiet sphere
By the rough torrent of occasion;
And have the *summary* of all our griefs,
When time shall serve, to show in articles.

Shakespeare. *Henry IV.*

When the parties proceed *summarily*, and they
chuse the ordinary way of proceeding, the cause is
made plenary.

Ayliffe.

In that comprehensive *summary* of our duty to
God, there is no express mention thereof.

Rogers.

The judge
Directed them to mind their brief,
Nor spend their time to shew their reading;
She'd have a *summary* proceeding.

Swift.

SUMMER, *n. s., v. n., & t.* Saxon *rumer*;
SUMMERHOUSE, *n. s.* [*v. a.* & Belg. *somer*; Goth. *sumar*. The season in which the sun arrives at the hither solstice: to pass the summer: to keep warm: a summerhouse is a garden apartment used chiefly in summer.

He was sitting in a *summer* parlour.

Judges iii. 20.

The fowls shall *summer* upon them, and all the
beasts shall winter upon them.

Isaiah xviii. 6.

Can't such things be,
And overcome us like a *summer's* cloud,
Without our special wonder? *Shakespeare. Macbeth.*
Maids well *summered*, and warm kept, are like
flies at Bartholomew-tide, blind, though they have
their eyes.

Shakespeare.

I'd rather live
With cheese and garlick, in a windmill, far
Than feed on cates, and have him talk to me,
In any *summerhouse* in Christendom.

Id. *Henry IV.*

In all the liveries decked of *summer's* pride.

Milton.

Dry weather is best for most *summer* corn.

Mortimer.

The dazzling roofs,
Resplendent as the blaze of *summer* noon,
Or the pale radiance of the midnight moon.

With here a fountain, never to be played,
And there a *summerhouse* that knows no shade.

Id. *Child of the sun,*

See sultry *summer* comes.

Thomson.

SUMMER, *n. s.* (*Trabs summaria*). The principal beams of a floor.

Oak, and the like true hearty timber, may be
better trusted in cross and transverse works for
summers, or girders, or binding beams.

Wotton.

SUMMER, one of the quarters of the year, when the year is divided into four quarters, or one-half when the year is divided only into summer and winter. In the former case, summer is the quarter during which, in northern climates, the sun passes through the signs Cancer, Leo, Virgo, or from the time of the greatest

declination, till the sun come to the equinoctial again, or have no declination; which is from about the 21st of June till about the 22d of September. In the latter case, summer contains the six warmer months, while the sun is on one side of the equinoctial; and winter the other six months, when the sun is on the other side of it. See METEOROLOGY.

SUMMER FALLOWING, in agriculture, a term applied to the process or practice of frequently ploughing and working over arable land at this season, with the view of clearing it of weeds. It is chiefly had recourse to for crops of the wheat kinds, but sometimes for those of the barley, turnip, and some other sorts, which require a fine mouldy clean state of the more superficial parts of the soil. Sir H. Davy in his Agricultural Chemistry has supposed that the chemical theory of summer-fallowing is very simple. It affords, it is said, no new source of riches to the soil or land; it merely tends to produce an accumulation of decomposing matter, which in the common course of crops would be employed as it is formed; and that it is scarcely possible to imagine a single instance of a cultivated soil, which can be supposed to remain in summer-fallow for a year with advantage to the farmer. The only cases where this practice can be beneficial, it is said, seem to be those in which it may be used for the destruction of weeds, and for cleansing such soils as are in a foul condition. In this ancient practice, which is still extensively made use of, the soil or mouldy surface earth is much exposed to the air, and submitted to different processes, which are purely of a mechanical nature. It is thought that the benefits arising from fallows, or fallowings, have been much over-rated; that a summer-fallow, fallowing, or a clean fallow, may sometimes be necessary on lands overgrown with weeds, especially if they be lands which cannot be pared and burnt with advantage; but that it is certainly unprofitable as a part of a general system in husbandry or management of land.

It has been supposed, it is said, by some writers, that certain principles necessary to fertility are derived from the atmosphere, which are exhausted by a succession of crops; and that these are again supplied during the repose of the land, and the exposure of the pulverised or broken down parts of the soil to the influence of the air; but that this, in truth, is not the case. The earths commonly found in soils cannot, it is said, be combined with more oxygen; none of them unite with azote; and such of them as are capable of attracting carbonic acid are always saturated with it in those soils on which the practice of summer-fallowing is adopted. The vague ancient opinion of the use of nitre, and of nitrous salts, in vegetation seems, it is said, to have been one of the principal speculative reasons for the defence of summer-fallows or fallowings. Nitrous salts are produced, it is said, during the exposure of soils containing vegetable and animal remains, and in the greatest abundance in hot weather; but that it is probably by the combination of azote from these remains with oxygen in the atmosphere, that the acid is formed; and at the

expense of an element which otherwise would have formed ammonia; the compounds of which are evidently much more efficacious than the nitrous compounds in assisting vegetation.

It is further noticed, on the subject, that when weeds are buried in the soil, by their gradual decomposition they furnish a certain quantity of soluble matter; but that it may be doubted whether there is as much useful manure in the land at the end of a clean fallow, or fallowing, as at the time the vegetables clothing the surface were first ploughed in. Carbonic acid gas is formed during the whole time by the action of the vegetable matter upon the oxygen of the air, and the greater part of it is lost to the soil in which it was formed, being dissipated in the atmosphere. The action of the sun, too, upon the surface of the soil or land tends, it is said, to disengage the gaseous and the volatile fluid matters that it contains; and heat increases the rapidity of fermentation; and, in the summer-fallow or fallowing, nourishment is rapidly produced, at a time when no vegetables are present capable of absorbing or drinking it up, by which much waste is the consequence.

It is justly concluded that land, when it is not employed in preparing food for animals, should be applied to the purpose of the preparation of manure for plants; which is effected by means of green crops, in consequence of the absorption of carbonaceous matter in the carbonic acid of the atmosphere. But that in a summer's fallow, or fallowing, a period is constantly lost, in which vegetables may be raised, either as food for animals, or as nourishment for the next crop; and that the texture of the soil or land is not so much improved by its exposure then as in the winter season, when the expansive powers of frost and ice, the gradual dissolution of snows, and the alternations from wet to dry, tend to pulverize and reduce it, and to blend its different parts together more fully. From these facts and circumstances it is evident that the practice of summer-fallowing should be had recourse to as little as possible by the farmer, as there is obviously much waste and loss by it in other ways than by the length of time the land lies idle and unproductive.

SUMMERSAULT, *n. s.* } Fr. *soubresault*.

SUMMERSET. } A high leap, in which the heels are thrown over the head.

And if at first he fail, his second *summersault*
He instantly assays. *Drayton*.

Some do the *summersault*,
And o'er the bar like tumblers vault. *Hudibras*.

Frogs are observed to use divers *summersaults*.
Walton.

The treasurer cuts a caper on the strait rope: I have seen him do the *sumerset* upon a trencher fixed on the rope, which is no thicker than a common packthread. *Swift*.

SUMMIT, *n. s.* Lat. *summitas*. The top, the utmost height.

Have I fall'n or no?

—From the dread *summit* of this chalky bourn!
Look up a-height, the shrill-gorged lark so far
Cannot be seen or heard. *Shakspeare. King Lear*.

Ætna's heat, that makes the *summit* glow,
Enriches all the vales below. *Swift*.

SUMMON, v. a. } Lat. *summono*. To call
SUMMONER, n. s. } with authority; admonish
SUMMONS. } to appear; cite; call up;
 excite: a summoner is he who cites or summons:
 summons, the call or admonition made; citation;
 authoritative call.

Catesby, sound lord Hastings,
 And summon him to-morrow to the Tower.
Shakspeare. Richard III.

Close pent up guilts,
 Rive your concealing continents, and ask
 These dreadful summoners grace. *Id. King Lear.*
 When the blast of war blows in our ears,
 Stiffen the sinews, summon up the blood.
Id. Henry V.

The tirsan is assisted by the governor of the city
 where the feast is celebrated, and all the persons of
 both sexes are summoned to attend. *Bacon.*

He sent to summon the seditious, and to offer par-
 don; but neither summons nor pardon was any thing
 regarded. *Hayward.*

The course of method summoneth me to discourse of
 the inhabitants. *Greiv's Survey of Cornwall.*

The sons of light
 Hasted, resorting to the summons high,
 And took their seats. *Milton's Paradise Lost.*

This summons, as he resolved unfit either to dispute
 or disobey, so could he not, without much violence
 to his inclinations, submit unto. *Fell.*

We are summoned in to profess repentance and
 amendment of all our sins. *Kettlewell.*

Nor trumpets summon him to war,
 Nor drums disturb his morning sleep. *Dryden.*

Love, duty, safety, summon us away;
 'Tis nature's voice, and nature we obey. *Pope.*

SUMOROKOF (Alexander), the founder of
 the Russian theatre, was the son of Peter Sumo-
 rokof, a Russian nobleman, born in Moscow,
 November 14th, 1527. He began his studies
 in his father's house; and afterwards received a
 liberal education at Petersburg, where he gave
 early proofs of a genius for poetry. On leaving
 the seminary of cadets, he was appointed adju-
 tant, first to count Colovkin, next to count Ro-
 somouski; and soon after was patronised by
 John count Shuvalof, the Mæcenas of Russia,
 who introduced him to the empress Elizabeth.
 In 1756 he wrote his celebrated tragedy of Ko-
 ref; which was first acted by some of his fellow
 cadets, who had previously performed a play of
 Racine's. The empress, hearing of this drama-
 tic phenomenon, expressed a desire to see it.
 It was accordingly performed in her presence;
 and the author and actors were highly applaud-
 ed. This encouraged Sumorokof to proceed in
 his dramatic career; and he produced, in suc-
 cession, the tragedies of, 1. Hamlet; 2. Aris-
 tona; 3. Sinaf and Truvor; 4. Zemira; 5. Di-
 misa; 6. Vitshelaf; 7. The False Demetrius;
 and 8. Micislaf. He was equally fertile in co-
 medy; and published, 9. Trisotinus; 10. The
 Judge; 11. The Dispute between Husband and
 Wife; 12. The Guardian; 13. The Portion ac-
 quired by Fraud; 14. The Envious Man; 15.
 Tartuffe; 16. The Imaginary Cuckold; 17. The
 Mother who Rivals her Daughter; 18. The
 Gossip; and, 19. The Three Royal Brothers.
 Mean time the empress Elizabeth rewarded his
 exertions, by raising him to the rank of a brig-
 adier, appointing him director of the Russian
 theatre, and settling upon him a pension of
 VOL. XXI.

£4000 a year. Catherine II. also honored and
 rewarded him: created him a counsellor of state,
 and conferred on him the order of St. Anne. He
 also attempted every species of poetry, except
 the epic; wrote two operas, viz. Alcestes, and
 Cephalus and Procris; and three historical
 tracts, viz. 1. A Chronicle of Moscow; 2. A
 History of the First Insurrection of the Strelitz,
 in 1682, by which prince John was appointed
 joint sovereign with Peter the Great, and the
 princess Sophia regent; and, 3. An Account of
 Stenko Razin's Rebellion. He died at Moscow,
 October 1st, 1777, aged nearly fifty-one.

SUMP, in metallurgy, a round pit of stone,
 lined with clay within, for receiving the metal
 on its first fusion from the ore.

SUMPH, in mining, denotes a pit sunk down
 in the bottom of the mine, to cut or prove the
 lode still deeper than before; and in order to
 slope and dig it away if necessary; and also to
 drive on the lode in depth. The sump prin-
 cipally serves as a basin or reservoir to collect
 the water of a mine together, that it may be cleaned
 out by an engine or machine.

SUMPTER, n. s. Fr. *sommier*; Ital. *somaro*.
 A horse that carries the clothes or furniture.

Return with her!
 Persuade me rather to be a slave and sumpter
 To this detested groom. *Id. King Lear.*

With full force his deadly bow he bent,
 And feathered fates among the mules and sumpter
 sent. *Dryden.*

Sumpter mules, bred of large Flanders mares.
Mortimer.

SUMPT'ION, n. s. Lat. *sumptus*. The act
 of taking. Not in use.

The *sumption* of the mysteries does all in a capable
 subject. *Taylor.*

SUMPTUOUS, adj. } Latin, *sumptuosus*,
SUMPTUARY, } *sumptus*. Costly; ex-
SUMPTUOS'ITY, n. s. } pensive; splendid:
SUMPTUOUSLY, adv. } *sumptuary* is, relating
SUMPTUOUSNESS, n. s. } to expense; regulating
 cost: *sumptuosity*, *costliness*: the adverb
 and noun substantive following agree with *sumptuous*.

We see how most Christians stood then affected,
 how joyful they were to behold the *sumptuous* state-
 liness of houses built unto God's glory. *Hooker.*

This monument five hundred years hath stood,
 Which I have *sumptuously* re-edified.
Shakspeare. Titus Andronicus.

He added *sumptuosity*, invented jewels of gold and
 stone, and some engines for the war. *Raleigh.*

To remove that material cause of sedition, which
 is want and poverty in the estate, serveth the open-
 ing and well balancing of trade, the banishing of
 idleness, the repressing of waste and excess by *sump-
 tuary* laws. *Bacon.*

I will not fall out with those that can reconcile
sumptuousness and charity. *Boyle.*

Ethelwold, bishop of Winchester, in a famine, sold
 all the rich vessels and ornaments of the church, to
 relieve the poor with bread; and said, There was no
 reason that the dead temples of God should be *sump-
 tuously* furnished, and the living temples suffer pen-
 ury. *Id. Apophthegms.*

We are too magnificent and *sumptuous* in our tables
 and attendance. *Atterbury.*

SUMPTUARY LAWS, *leges sumptuarie*, are laws
 made to restrain excess in apparel, costly furni-
 2 D

ture, eating, &c. Most ages and nations have had their sumptuary laws; and some retain them still. But it is observed that no laws are worse executed than sumptuary laws. Political writers have been much divided in opinion with respect to the utility of these laws to a state. Montesquieu observes that luxury is necessary in monarchies, as in France, but ruinous to democracies, as in Holland. With regard to England, whose government is compounded of both species, it may still be a dubious question, says judge Blackstone, how far private luxury is a public evil, and as such cognisable by public laws. The sumptuary laws of that ancient Locrian legislator Zaleucus are famous: by these it was ordained that no woman should go attended by more than one maid in the street, except she were drunk: that she should not go out of the city in the night, unless she went to commit fornication: that she should not wear any gold or embroidered apparel, unless she proposed to be a common strumpet; and that men should not wear rings or tissues except when they went a whoring, &c. Among the Romans, the sumptuary laws were very numerous: by the Lex Orchia, the number of guests at feasts was limited, though without any limitation of the charges: by the Fannian law, made twenty-two years afterwards, it was enacted that more than ten asses should not be spent at any ordinary feast: for the solemn feasts, as the Saturnalia, &c., 100 asses were allowed; ten of which, Gellius informs us, was the price of a sheep, and 100 of an ox. By the Didian law, which was preferred eighteen years after, it was decreed that the former sumptuary laws should be in force, not only in Rome, but throughout all Italy; and that for every transgression, not only the master of the feast, but all the guests too should be liable to the penalty. The English have had their share of sumptuary laws, chiefly made in the reigns of Edward III., Edward IV., and Henry VIII., against shoes with long points, short doublets, and long coats; all repealed by stat. 1 Jac. I. c. 25. As to excess in diet, there remains still one law unrepealed. Under king Henry IV., Camden tells us, pride was got so much into the foot that it was proclaimed that no man should wear shoes above six inches broad at the toes. And their other garments were so short that it was enacted, 25 Edward IV., that no person under the condition of a lord should, from that time, wear any mantle or gown, unless of such length, that it might reach below his waist.

SUMY, a large town of European Russia, in the government of Charkov, on the Psol. It is surrounded with a wall and ditch, and defended by an old citadel. Chiefly built of wood and wretchedly paved; it still contains several excellent charitable institutions, and public depôts and warehouses. It is the chief place of a circle, and agriculture, tillage, or pasturage, forms the chief employment of the inhabitants; for the only manufacture is the distilling of spirits. The traffic is considerable, but confined in a great measure to four annual fairs, which a number both of Greek and Russian merchants attend. Inhabitants 11,000. Ninety miles north-west of Charkov.

SUN, *n. s. & v. a.*

SUN'BEAM, *n. s.*

SUN'BEAT, *adj.*

SUN'BRIGHT,

SUN'BURNING, *n. s.*

SUN'BURNT, *adj.*

SUN'DAY, *n. s.*

SUN'LESS, *adj.*

SUN'LIKE

SUN'NY,

SUN'RISE, *n. s.*

SUN'RISING,

SUN'SET,

SUN'SHINE,

SUN'SHINY, *adj.*

Sax. *sonna*; Goth. *sunno*; Swed. *son*; Teut. *sonne*; Belg. *zou*. The luminary of day; a place particularly warmed by the sun; any thing eminently splendid or great: 'under the sun' is, in this world: to sun is to expose to, or warm in the sun: Sunday is treated of at large below: sunless is wanting sun or warmth: sunny, resembling the sun; bright as sunbeams; exposed to or colored by the sun: the other compounds are of obvious meaning.

There is no new thing *under the sun*.

Ecclesiasticus i. 9.

Doth beauty keep which never *sun* can burn,
Nor storms do turn? *Sidney*.

The fruitful-headed beast amazed
At flashing beams of that *sunshiny* shield,
Became stark blind, and all his senses dazed,
That down he tumbled. *Spenser*.

She saw Duessa *sunny* bright,
Adorned with gold and jewels shining clear. *Id.*

Gathering up himself out of the mire,
With his uneven wings did fiercely fall
Upon his *sunbright* shield. *Id.*

The cry to shady delve him brought at last,
Where Mammon earst did *sun* his treasury. *Id.*

Her *sun* locks
Hang on her temples like a golden fleece. *Shakspeare*.

Bid her steal into the pleached bower,
Where honey-suckles, ripened by the *sun*,
Forbid the *sun* to enter. *Id.*

An' she were not kin to me, she would be as fair
on Friday as Helen is on Sunday.

Id. Troilus and Cressida.

The Roman eagle, winged
From the spongy south to this part of the west,
Vanished in the sunbeams. *Id. Cymbeline*.

My decayed fair
A *sunny* look of his would soon repair. *Shakspeare*.

If thou canst love a fellow of this temper, Kate,
whose face is not worth *sunburning*, let thine eye be
thy cook. *Id.*

Now would I have thee to my tutor,
How and which way I may bestow myself,
To be regarded in her *sunbright* eye. *Id.*

When the *sun* sets the air doth drizzle dew;
But for the *sunset* of my brother's son
It rains downright. *Id.*

Send out a pursuivant
To Stanley's regiment; bid him bring his power
Before *sun-rising*. *Id. Richard III.*

That man that sits within a monarch's heart,
And ripens in the *sunshine* of his favour,
Would he abuse the countenance of the king,
Alack, what mischiefs might be set abroad,
In shadow of such greatness! *Id. Henry IV.*

In those days the giants of Libanus mastered all
nations, from the *sunrising* to the *sunset*.

Raleigh's History.

The stars are of greater use than for men to gaze on
after *sun-set*. *Raleigh*.

I will never consent to put out the *sun* of sove-
reignty to posterity, and all succeeding kings.

King Charles.

He had been many years in that *sunshine*, when a
new comet appeared in court. *Clarendon*.

Where such radiant ights have shone,
No wonder if her cheeks be grown
Sunburnt with lustre of her own. *Cleaveland.*

I that in his absence
Blazed like a star of the first magnitude,
Now in his brighter *sunshine* am not seen.
Denham's Sophy.

High in the midst exalted as a God,
The' apostate in his *sunbright* chariot sat,
Idol of majesty divine! inclosed
With flaming cherubims and golden shields. *Milton.*

SUN, SOL, ☉. See ASTRONOMY, INDEX. The sun is certainly that celestial body which of all others should most attract our attention. It has accordingly employed much of the time and meditation, not only of the astronomer, but also of the speculative philosopher, in all ages of the world; and many hypotheses have been formed, and some discoveries made respecting the nature and the uses of this vast luminary. Sir Isaac Newton has shown that the sun, by its attractive power, retains the planets of our system in their orbits: he has also pointed out the method whereby the quantity of matter which it contains may be accurately determined. Dr. Bradley has assigned the velocity of the solar light with a degree of precision exceeding our utmost expectation. Galileo, Scheiner, Hevelius, Cassini, and others, have ascertained the rotation of the sun upon its axis, and determined the position of its equator. By means of the transit of Venus over the disk of the sun, mathematicians have calculated its distance from the earth, its real diameter and magnitude, the density of the matter of which it is composed, and the fall of heavy bodies on its surface. We have therefore a very clear notion of the vast importance and powerful influence of the sun on its planetary system; but, with regard to its internal construction, we are yet extremely ignorant. Many ingenious conjectures have indeed been formed on the subject; a few of which we shall mention as an introduction to Dr. Herschel's, of which, as it is the latest, and perhaps the most plausible, we shall give a pretty full account, nearly in his own words. The dark spots in the sun, for instance, have been supposed to be solid bodies revolving very near its surface. They have been conjectured to be the smoke of volcanoes, or the scum floating upon an ocean of fluid matter. They have also been taken for clouds. They were explained to be opaque masses swimming on the fluid matter of the sun, dipping down occasionally. It has been supposed that a fiery liquid surrounded the sun, and that, by its ebbing and flowing, the highest parts of it were occasionally uncovered, and appeared under the shape of dark spots; and that, by the return of the fiery liquid, they were again covered, and in that manner successively assumed different phases. The sun itself has been supposed to be a globe of fire. The waste it would undergo by a gradual consumption, on the supposition of its being ignited, has been ingeniously calculated; and in the same point of view its immense power of heating the bodies of such comets as draw very near to it has been assigned. In 1779 there was a spot on the sun which was large enough to be seen with the naked eye. By

a view of it with a seven feet reflector, charged with a very high power, it appeared to be divided into two parts. The largest of the two, on the 19th of April, measured $1' 8.06''$ in diameter, which is equal in length to more than 31,000 miles. Both together must certainly have extended above 50,000. 'The idea of its being occasioned by a volcanic explosion violently driving away a fiery fluid, ought to be rejected,' says Dr. Herschel, 'on many accounts. To mention only one, the great extent of the spot is very unfavorable to such a supposition. Indeed a much less violent and less pernicious cause may account for all the appearances of the spot. When we see a dark belt near the equator of the planet Jupiter, we do not recur to earthquakes and volcanoes for its origin. An atmosphere, with its natural changes, will explain such belts. Our spot on the sun may be accounted for on the same principles. The earth is surrounded by an atmosphere composed of various elastic fluids. The sun also has its atmosphere; and, if some of the fluids which enter into its composition should be of a shining brilliancy, in the manner that will be explained hereafter, while others are merely transparent, any temporary cause which may remove the lucid fluid, will permit us to see the body of the sun through the transparent ones. If an observer were placed on the moon, he would see the solid body of the earth only in those places where the transparent fluids of our atmosphere would permit him. In others, the opaque vapors would reflect the light of the sun without permitting his view to penetrate to the surface of our globe. He would probably also find that our planet had occasionally some shining fluids in its atmosphere: as, not unlikely, some of our northern lights might not escape his notice, if they happened in the unenlightened part of the earth, and were seen by him in his long dark night. Nay, we have pretty good reason to believe, that probably all the planets emit light in some degree; for the illumination which remains on the moon in a total eclipse cannot be entirely ascribed to the light which may reach it by the refraction of the earth's atmosphere. For instance, in the eclipse of the moon October 22d, 1790, the rays of the sun refracted by the atmosphere of the earth towards the moon, admitting the mean horizontal refraction to be $30' 50.8''$, would meet in a focus 189,000 miles beyond the moon; so that consequently there could be no illumination from rays refracted by our atmosphere. It is, however, not improbable that about the polar regions of the earth there may be refraction enough to bring some of the solar rays to a shorter focus. The distance of the moon at the time of the eclipse would require a refraction of $54' 6''$, equal to its horizontal parallax at that time, to bring them to a focus so as to throw light on the moon. The unenlightened part of the planet Venus has also been seen by different persons; and, not having a satellite, those regions that are turned from the sun cannot possibly shine by a borrowed light; so that this faint illumination must denote some phosphoric quality of the atmosphere of Venus.'

In the instance of the large spot on the sun

already mentioned, Dr. Herschell concludes from appearances, that he viewed the real body of the sun itself, of which we rarely see more than its shining atmosphere. In 1783 he observed a fine large spot, and followed it up to the edge of the sun's limb. Here he took notice that the spot was plainly depressed below the surface of the sun, and that it had very broad shelving sides. He also suspected some part, at least, of the shelving sides to be elevated above the surface of the sun; and observed that, contrary to what usually happens, the margin of that side of the spot which was farthest from the limb was the broadest. The luminous shelving side of a spot may be explained by a gentle and gradual removal of the shining fluid, which permits us to see the globe of the sun. As to the uncommon appearance of the broadest margin being on that side of the spot which was farthest from the limb when the spot came near the edge of it, we may surmise that the sun has inequalities on its surface, which may possibly be the cause of it. For, when mountainous countries are exposed, if it should chance that the highest parts of the landscape are situated so as to be near that side of the margin or penumbra of the spot which is towards the limb, they may partly intercept our view of it when the spot is seen very obliquely. This would require elevations at least 500 or 600 miles high; but, considering the great attraction exerted by the sun upon bodies at its surface, and the slow revolution it has upon its axis, we may readily admit inequalities to that amount. From the centrifugal force at the sun's equator, and the weight of bodies at its surface, he computes that the power of throwing down a mountain by the exertion of the former, balanced by the superior force of keeping it in its place of the latter, is nearly six times and a half less on the sun than on our equatorial regions; and, as an elevation similar to one of three miles on the earth would not be less than 334 miles on the sun, there can be no doubt but that a mountain much higher would stand very firmly. The little density of the solar body seems also to be in favor of the height of its mountains; for, *cæteris paribus*, dense bodies will sooner come to their level than rare ones. The difference in the vanishing of the shelving side, instead of explaining it by mountains, may also, and perhaps more satisfactorily, be accounted for from the real difference of the extent, the arrangement, the height, and the intensity of the shining fluid, added to the occasional changes that may happen in these particulars during the time in which the spot approaches to the edge of the disk. However, by admitting large mountains on the face of the sun, we shall account for the different opinions of two eminent astronomers; one of whom believed the spots depressed below the surface of the sun, while the other believed them elevated above it. For it is not impossible that some of the solar mountains may be high enough occasionally to project above the shining elastic fluid, when, by some agitation or other cause, it is not of the usual height: and this opinion is much strengthened by the return of some remarkable spots which served Cassini to ascertain the period of the sun's rotation. A

very high country, or chain of mountains, may oftener become visible, by the removal of the obstructing fluid, than the lower regions, on account of its not being so deeply covered with it. In 1791 the doctor examined a large spot on the sun, and found it evidently depressed below the level of the surface. In 1792 he examined the sun with several powers from ninety to 500, when it appeared evident, that the black spots are the opaque ground, or body of the sun; and that the luminous part is an atmosphere, which, being interrupted or broken, gives us a transient glimpse of the sun itself. He perceived, likewise, that the shining surface of the sun is unequal, many parts of it being elevated and others depressed; and that the elevations, to which Hevelius gave the name of *faculæ*, so far from resembling torches, were rather like the shrivelled elevations upon a dried apple, extended in length, and most of them joined together, making waves or waving lines. The *faculæ* being elevations, very satisfactorily explains the reason why they disappear towards the middle of the sun, and reappear on the other margin; for, about the place where we lose them, they begin to be edge-wise to our view; and, if between the *faculæ* should lie dark spots, they will most frequently break out in the middle of the sun, because they are no longer covered by the side views of these *faculæ*. The doctor gives a very particular account of all his observations, which seem to have been accurately made, and we need scarcely add with excellent telescopes. For that account, however, we must refer to the memoir itself, and hasten to lay before our readers the result of his observations.

'That the sun,' says he, 'has a very extensive atmosphere, cannot be doubted; and that this atmosphere consists of various elastic fluids, that are more or less lucid and transparent, and of which the lucid one is that which furnishes us with light, seems also to be fully established by all the phenomena of its spots, of the *faculæ*, and of the lucid surface itself. There is no kind of variety in these appearances but what may be accounted for with the greatest facility, from the continual agitation which, we may easily conceive, must take place in the regions of such extensive elastic fluids. It will be necessary, however, to be a little more particular as to the manner in which I suppose the lucid fluid of the sun to be generated in its atmosphere. An analogy that may be drawn from the generation of clouds in our own atmosphere, seems to be a very proper one, and full of instruction. Our clouds are probably decompositions of some of the elastic fluids of the atmosphere itself, when such natural causes, as in this grand chemical laboratory are generally at work, act upon them: we may therefore admit that in the very extensive atmosphere of the sun, from causes of the same nature, similar phenomena will take place; but with this difference, that the continual and very extensive decompositions of the elastic fluids of the sun are of a phosphoric nature, and attended with lucid appearances, by giving out light. If it should be objected, that such violent and unremitting decompositions would exhaust the sun, we may recur again to

our analogy, which will furnish us with the following reflections.—The extent of our own atmosphere, we see, is still preserved, notwithstanding the copious decompositions of its fluids in clouds and falling rain; in flashes of lightning; in meteors, and other luminous phenomena; because there are fresh supplies of elastic vapors continually ascending to make good the waste occasioned by these decompositions. But it may be urged that the case with the decomposition of the elastic fluids in the solar atmosphere would be very different, since light is emitted, and does not return to the sun, as clouds do to the earth when they descend in showers of rain. To which I answer, that, in the decomposition of phosphoric fluids, every other ingredient but light may also return to the body of the sun. And that the emission of light must waste the sun is not a difficulty that can be opposed to our hypothesis; for as it is an evident fact that the sun does emit light, the same objection, if it could be one, would equally militate against every other assignable way to account for the phenomenon. There are, moreover, considerations that may lessen the pressure of this alleged difficulty. We know the exceeding subtlety of light to be such, that in ages of time its emanation from the sun cannot very sensibly lessen the size of this great body. To this may be added, that very possibly there may always be ways of restoration to compensate for what is lost by the emission of light, though the manner in which this can be brought about should not appear to us. Many of the operations of nature are carried on in her great laboratory which we cannot comprehend; but now and then we see some of the tools with which she is at work. We need not wonder that their construction should be so singular as to induce us to confess our ignorance of the method of employing them; but we may rest assured that they are not a mere *lusus natureæ*. Here he alludes to the great number of small telescopic comets; which he supposes, as others had done before him, may be employed to restore to the sun what had been lost by the emission of light. ‘My hypothesis, however,’ continues he, ‘does not lay me under any obligation to explain how the sun can sustain the waste of light, nor to show that it will sustain it for ever; and I should also remark that, as in the analogy of generating clouds, I merely allude to their production as owing to a decomposition of some of the elastic fluids of our atmosphere, that analogy, which firmly rests upon the fact, will not be less to my purpose, to whatever cause these clouds may owe their origin. It is the same with the lucid clouds, if I may so call them, of the sun. They plainly exist, because we see them; the manner of their being generated may remain an hypothesis—and mine, till a better can be proposed, may stand good; but, whether it does or not, the consequences I am going to draw from what has been said, will not be affected by it.’ Before he proceeds to draw these consequences, he informs us that, according to the above theory, a dark spot in the sun is a place in its atmosphere, which happens to be free from luminous decompositions; that *faculæ* are, on the contrary, more copious mixtures of

such fluids as decompose each other; and that the regions in which the luminous solar clouds are formed, adding thereto the elevation of the *faculæ*, cannot be less than 1843, nor much more than 2765 miles in depth. It is true, continues he, that in our atmosphere the extent of the clouds is limited to a very narrow compass; but we ought rather to compare the solar ones to the luminous decompositions which take place in our aurora borealis, or luminous arches, which extend much farther than the cloudy regions. The density of the luminous solar clouds, though very great, may not be exceedingly more so than that of our aurora borealis. For if we consider what would be the brilliancy of a space 2000 or 3000 miles deep, filled with such conruscations as we see now and then in our atmosphere, their apparent intensity, when viewed at the distance of the sun, might not be much inferior to that of the lucid solar fluid. From the luminous atmosphere of the sun, he proceeds to its opaque body; which, by calculation from the power it exerts upon the planets, we know to be of great solidity; and from the phenomena of the dark spots, many of which, probably on account of their high situations, have been repeatedly seen, and otherwise denote inequalities in their level, we surmise that its surface is diversified with mountains and valleys. What has been said enables us to come to some very important conclusions, by remarking that this way of considering the sun and its atmosphere removes the great dissimilarity we have hitherto been used to find between its condition and that of the rest of the great bodies of the solar system. The sun, viewed thus, appears to be nothing else than a very eminent, large, and lucid planet, evidently the first, or, in strictness of speaking, the only primary one of our system, all others being truly secondary to it. Its similarity to the other globes of the solar system with regard to its solidity, its atmosphere, and its diversified surface, the rotation upon its axis, and the fall of heavy bodies, leads us on to suppose that it is most probably also inhabited, like the rest of the planets, by beings whose organs are adapted to the peculiar circumstances of that vast globe. It may, however, not be amiss to remove a certain difficulty, which arises from the effect of the sun’s rays upon our globe. The heat which is here, at the distance of 95,000,000 miles, produced by these rays, is so considerable that it may be objected, that the surface of the globe of the sun itself must be scorched up beyond all conception. This may be very substantially answered by many proofs drawn from natural philosophy, which show that heat is produced by the sun’s rays only when they act upon a calorific medium; they are the cause of the production of heat, by uniting with the matter of fire which is contained in the substances that are heated; as the collision of flint and steel will inflame a magazine of gunpowder, by putting all the latent fire it contains into action. But an instance or two of the manner in which the solar rays produce their effect will bring this home to our most common experience. On the tops of mountains of a sufficient height, at an altitude where clouds can very seldom reach to shelter them from the direct rays

of the sun, we always find regions of ice and snow. Now, if the solar rays themselves conveyed all the heat we find on this globe, it ought to be hottest where their course is least interrupted. Again, our aeronauts all confirm the coldness of the upper regions of the atmosphere; and since, therefore, even on our earth, the heat of any situation depends upon the aptness of the medium to yield to the impression of the solar rays, we have only to admit that, on the sun itself, the elastic fluids composing its atmosphere, and the matter on its surface, are of such a nature as not to be capable of any excessive affection from its own rays; and indeed this seems to be proved by the copious emission of them; for if the elastic fluids of the atmosphere, or the matter contained on the surface of the sun, were of such a nature as to admit of an easy chemical combination with its rays, their emission would be much impeded. Our author then proceeds to support his theory by analogical reasonings; but, as these will occur to such of our readers as are conversant with the speculations of astronomers, we pass on to his reflections upon the consequences of this theory. 'That the stars are suns can hardly admit of a doubt. Their immense distance would perfectly exclude them from our view, if the light they send us were not of the solar kind. Besides, the analogy may be traced much farther. The sun turns on its axis, so does the star Algol; so do the stars called β Lyræ, δ Cephei, η Antinoi, σ Ceti, and many more; most probably all. From what other cause can we so probably account for their periodical changes? Again, our sun has spots on its surface; so has the star Algol, and so have the stars already named, and probably every star in the heavens. On our sun these spots are changeable; so they are on the star σ Ceti, as evidently appears from the irregularity of its changeable lustre, which is often broken in upon by accidental changes, while the general period continues unaltered. The same little deviations have been observed in other periodical stars, and ought to be ascribed to the same cause. But if stars are suns, and suns are inhabitable, we see at once what an extensive field for animation opens itself to our view. It is true that analogy may induce us to conclude that since stars appear to be suns, and suns, according to the common opinion, are bodies that serve to enlighten, warm, and sustain a system of planets, we may have an idea of numberless globes that serve for the habitation of living creatures. But, if these suns themselves are primary planets, we may see some thousands of them with our own eyes, and millions by the help of telescopes, when at the same time the same analogical reasoning still remains in full force with regard to the planets which these suns may support.' The doctor then observes that, from other considerations, the idea of suns or stars being merely the supporters of systems or planets, is not absolutely to be admitted as a general one. 'Among the great number of very compressed clusters of stars I have given,' says he, 'in my catalogue, there are some which open a different view of the heavens to us. The stars in them are so very close

together, that, notwithstanding the great distance at which we may suppose the cluster itself to be, it will hardly be possible to assign any sufficient mutual distance to the stars composing the cluster, to leave room for crowding in those planets for whose support these stars have been, or might be, supposed to exist. It should seem, therefore, highly probable, that they exist for themselves; and are, in fact, only very capital, lucid, primary planets, connected together in one great system of mutual support. The same remark may be made with regard to the number of very close double stars, whose apparent diameters being alike, and not very small, do not indicate any very great mutual distance, from which, however, must be deducted all those where the different distances may be compensated by the real difference in their respective magnitudes. To what has been said may be added, that, in some parts of the milky way, where yet the stars are not very small, they are so crowded that in 1792, August 22d, I found by the gauges, that in forty-one minutes of time, no less than 258,000 of them had passed through the field of view of my telescope. It seems, therefore, upon the whole, not improbable, that in many cases stars are united in such close systems as not to leave much room for the orbits of planets or comets; and that consequently, upon this account also, many stars, unless we would make them mere useless brilliant points, may themselves be lucid planets, perhaps unattended by satellites.' What a magnificent idea does this theory give of the universe, and of the goodness, as well as power, of its Author! And how cold must be that heart, and clouded that understanding, which, after the contemplation of it, can for one moment listen to the atheistical doctrines of those men who presume to account for all the phenomena of nature by chemical affinities and mechanical attraction! The man who, even in his heart, can say that such an immense system, differing so widely in the structure of the different parts of it, but every where crowded with life, is the effect of unintelligent agency, is indeed, to use the emphatic language of an ancient astronomer—a fool.

SUNAPEE, a lake of the United States, in New Hampshire, in the townships of Fisherfield, Wendell, and New London. It is eleven miles long, and one and a half broad. Little Sunapee, two miles long, lies north-east in New London.

SUNART, Loch, a navigable inlet of the sea, between the counties of Argyle and Inverness, in Scotland, about twenty miles long, and from one and a half to two miles broad. Also the name of the district bordering on the Loch.

SUNDA, STRAITS OF. An arm of the sea which separates the islands of Sumatra and Java; by the Malays it is termed Sunda Kalapa. The length of this channel, taken from the flat point to Varkens, or Hog Point, is about seventy miles, and on the opposite coast, from Java Head to Bantam Point, about ninety. In the mouth lies Prince's Island, by the situation of which two passages are formed; one between Prince's Island and Java, which is made use of for the most part by ships which have to pass the straits during the south-east monsoon, in

order that, sailing close in with the Java shore, they may soon get within anchoring depth. The other passage, called by seamen the Great Channel, sometimes also serves as an entrance to the straits during the south-east monsoon, but it is with the greatest difficulty, and after continual struggling with the south-easterly winds and the current that this can be effected. In the narrowest part of the straits, opposite to Hog's Point, on Sumatra, lies an island that on account of its situation has been called Thwart the Way, or Middle Isle. A strong current runs through the passage on both sides of this island during the whole year, setting with the prevailing easterly or westerly winds, either to the north-east or south-west. The chief islands in these straits are Prince's Isle, Krakatau, Thwart the Way, and Pulo Baby. The others are very insignificant, mostly level, founded on beds of coral and covered with trees. A few have steep naked sides, and at a little distance resemble old castles, mouldering into ruins; but, on a nearer view, appear to be of volcanic origin. The Dutch East India Company claim an absolute sovereignty over the Straits of Sunda, but it never has been enforced.

SUNDAY, or the Lord's-day, is a solemn festival observed by Christians on the first day of every week, in memory of our Saviour's resurrection. See SABBATH. In the breviary and other offices we meet with Sundays of the first and second class. Those of the first class are Palm, Easter, Advent, and Whitsunday, those of Quasimodo and Quadragesima. Those of the second class are the common Sundays. Anciently each Sunday in the year had its particular name, which was taken from the introit of the day; which custom has only been continued to some few in Lent; as Reminiscere, Lætare, Oculi, Judica. The Lord's day, mentioned in the Apocalypse, is certainly our Sunday; which was very early instituted by the apostles. A regard was had to this day in the earliest ages of the church, as appears from the first apology of Justin Martyr, where he describes the exercise of the day not much unlike to ours. See SABBATH. But Constantine the Great first made a law for the proper observation of Sunday; and, according to Eusebius, appointed it to be regularly celebrated throughout the Roman empire. Before him, and even in his time, they observed the Jewish Sabbath as well as Sunday. By his law, made in 321, it was decreed, that the Sunday should be kept a day of rest in all cities and towns; but the country people were allowed to follow their work. In 338 the council of Orleans prohibited country labor; but because there were still many Jews in Gaul, and the people fell into many superstitious usages in the celebration of the new Sabbath, like those of the Jews among that of the old, the council declares that to hold it unlawful to travel with horses, cattle, and carriages, to prepare food, or to do any thing necessary to the cleanliness and decency of houses or persons, savours more of Judaism than of Christianity. See SABBATH-BREAKING.

The appellation of Lord's day was adopted and applied to the first day of the week by the Christian writers. At the time when St. John

wrote the book of his revelation, the first day of the week seems to have obtained this name (Rev. i. 10); and this name, together with St. John's use of it, sufficiently denotes the appropriation of the day to the service of religion; as well as that this appropriation was perfectly known to the churches of Asia. We have reason to believe that, by the 'Lord's day,' was meant the 'first' day of the week; because we find no traces of any distinction of days, which could entitle any other to that appellation; accordingly this appellation was used both by the Greek and Latin churches. So it is styled by Clemens Alexandrinus, by Ignatius, by Dionysius, bishop of Corinth, by an African synod, and by Tertullian. Sometimes, indeed, it is simply called *ἡ κυριακή*, and 'Dominicus,' that is, 'the Lord's,' without the addition of the word 'day,' as it is thus called *την κυριακήν* by Ignatius, and 'Dominicus' by Cyprian. Clemens Alexandrinus writes to this effect:—that a true Christian, according to the commandment of the gospel, observes the Lord's day, by casting out all evil thoughts and entertaining all good ones, glorifying the resurrection of the Lord on that day.' Barnabas says, 'we keep the eighth day with gladness, on which Christ arose from the dead;' and Ignatius also says, 'let us keep the Lord's day, on which our life arose through him.' Justin Martyr also relates, that 'on Sunday the Christians assembled together, because it was the first day of the week, on which God out of the confused chaos made the world, and Jesus Christ our Saviour arose from the dead; for on Friday he was crucified, and on Sunday he appeared to his apostles and disciples, and taught them those things which the Christians now believe.' To the same purpose, Origen advises his auditors to pray unto Almighty God, 'especially on the Lord's day, which is a commemoration of Christ's passion; for the resurrection of Christ is not only celebrated once a year, but every seven days.' That this day was denominated '*Sunday*' at a very early period, is evinced by a variety of testimonies, which it is needless to cite. Justin Martyr and Tertullian in particular use this appellation. But, though they so far complied with the Heathens to call this day Sunday, yet they do not seem to have so far indulged the Jews as to call it the 'Sabbath-day;' for through all their writings they violently declaim against sabbatizing, or keeping the sabbath-day, that is the Judaical observance of the seventh day, which we must always understand by the word 'Sabbatum' in the writings of the ancients, not the observance of the first day, or the Lord's day; for that was constantly celebrated: and, by those who condemn the observance of the sabbath-day, the sanctification of the Lord's day is approved and recommended, as by Justin Martyr and Tertullian, and also by Ignatius, who says in one place, 'let us no longer sabbatize,' and in another, 'instead of sabbatizing, let every Christian keep the Lord's day, the day on which Christ arose again; the queen of days, on which our life arose, and death was conquered by Christ.' The Eastern churches, however, in compliance with the Jewish converts, who were numerous in those parts, performed on the seventh day the

same public religious services that they did on the first, observing both the one and the other. Whence Origen enumerates Saturday as one of the four feasts solemnised in his time; though, on the contrary, some of the Western churches, that they might not seem to judaize, fasted on Saturday.

The principal arguments pertaining to this question have been glanced at under the article SABBATH. Paley, who adopted the opinion of those who maintain that the institution of the Jewish sabbath first took place in the wilderness, considers, as they do, the blessing and sanctification, i. e. the religious distinction and appropriation of the seventh day, mentioned in the book of Genesis, as not having been made till many ages afterwards. He alleges that the words do not assert, that God then 'blessed' and 'sanctified' the seventh day, but that he blessed and sanctified it, because he had on that day rested from the work of creation, and for that reason: and if it be asked, why the sabbath, or sanctification of the seventh day, was then mentioned, if it was not then appointed, our author replies, that the order of connexion, and not of time, introduced the mention of the sabbath in the history of the subject which it was ordained to commemorate. This interpretation, he says, is strongly supported by a passage in the prophecy of Ezekiel, where the sabbath is plainly spoken of as given, or, as the expression is supposed to mean, as first instituted, in the wilderness. Ezek. xx. 10, 11, 12. Nehemiah also accounts the promulgation of the sabbatic law amongst the transactions in the wilderness, and this circumstance is considered as affording another important argument in favor of the same opinion. Nehem. ix. 14. If the divine command, by which the sabbath was instituted, was actually delivered at the creation, as many learned writers have maintained, it was without doubt addressed to the whole human species alike, and continues, unless repealed by some subsequent revelation, obligatory upon all who have the knowledge of it. But, if the command was published for the first time in the wilderness, then it was immediately directed to the Jewish people alone, and the sabbath ought to be regarded as part of the peculiar law of the Jewish policy. In farther support of this latter opinion, it is alleged that the sabbath is described as a sign between God and the people of Israel (Exod. xxxi. 16, 17, Ezek. xx. 16); and that it does not seem easy to understand how the sabbath could be a 'sign' between God and the people of Israel, unless the observance of it was peculiar to that people, and designed to be so. The distinction of the sabbath is, in its nature, as much a positive ceremonial institution as that of many other seasons which were appointed by the Levitical law to be kept holy, and to be observed by a distinct rest: such were the first and seventh days of unleavened bread; the feast of pentecost; the feast of tabernacles; and, in the twenty-third chapter of Exodus, the sabbath and these are recited together. It is further argued, that the observance of the sabbath was not one of the articles enjoined by the apostles in the fifteenth chapter of Acts, upon them 'which, from

among the Gentiles, were turned unto God.' St. Paul evidently appears to have considered the sabbath as part of the Jewish ritual, and not binding upon Christians as such. Col. ii. 16, 17.

If the law by which the Sabbath was instituted be considered as a law only to the Jews, it becomes an important enquiry, whether the founder of Christianity delivered any new command upon the subject; or, if that should not appear to be the case, whether any day was appropriated to the service of religion by the authority or example of his apostles? The practice of holding religious assemblies upon the first day of the week was so early and universal in the Christian church, that we derive hence considerable proof of its having originated from some precept of Christ, or of his apostles, though no such precept be now extant. It was on the first day of the week that the disciples were assembled, when Christ appeared to them for the first time after his resurrection. John xx. 19. If we allow that this might have been accidental, yet we read in the twenty-sixth verse of the same chapter, 'that after eight days,' that is, on the first day of the week following, 'again the disciples were within,' which second meeting upon the same day of the week seems like an appointment and design to meet on that particular day. The same custom seems also to have been observed in a Christian church at a great distance from Jerusalem. Acts xx. 6, 7. The practice mentioned in this passage seems now to have been familiar and established. See also 1 Cor. xvi. 1, 2. From these passages we deduce ample evidence that the Christians held and frequented religious assemblies upon the first day of the week. Nevertheless, a cessation upon that day from labor, beyond the time of attendance upon public worship, is not intimated in any passage in the New Testament; nor did Christ or his apostles deliver, as Paley supposes, any command to their disciples for a discontinuance upon that day of the common offices of their respective professions. This reserve cannot be censured as a defect in the Christian institution by any who consider that, in the primitive condition of Christianity, the observation of a new sabbath would have been useless, or inconvenient, or impracticable. During Christ's personal ministry, his religion was preached to the Jews alone. They already had a sabbath, which, as subjects of that economy, they were obliged to keep, and did keep. It was not, therefore, probable that Christ would enjoin another day of rest in conjunction with this.

Dr. Paley deduces from his whole enquiry on this subject the conclusion that the assembling upon the first day of the week, for the purpose of public worship and religious instruction, is a law of Christianity, of divine appointment; and that the resting on that day from our employments, longer than we are detained from them by an attendance upon these assemblies, is to Christians an ordinance of human institution; binding, nevertheless, upon the conscience of every individual of a country in which a weekly sabbath is established, for the sake of the beneficial purposes which the public and regular observance of it promotes; and recommended, perhaps, in some

degree, to the divine approbation, by the resemblance it bears to what God was pleased to make a solemn part of the law which he delivered to the people of Israel, and by its subserviency to many of the same uses. In general, we may observe, that if the design of a religious assembly require that it be held frequently, it is most expedient that it should return at stated intervals; and that the same seasons should be observed throughout the country. That part of the religious distinction of seasons, which consists in a general intermission of labor and business during times set apart for the exercise of public worship, is founded in the reasons which make public worship itself a duty. But, as the celebration of divine service never occupies the whole day, the other interval of Sunday, that is not spent at church, must be considered as a mere rest from the ordinary occupations of civil life; and he, says Paley, who would defend the institution, as it is required to be observed in Christian countries, unless he can produce a command for 'a Christian sabbath,' must point out the uses of it in that view. First, that interval of relaxation which Sunday affords to the laborious class of mankind contributes, in a great degree, to the comfort and satisfaction of their lives, both as it refreshes them for the time, and as it relieves their six days' labor by the prospect of a day of rest always approaching. In this view of the institution, whatever may be its origin, it must appear to be highly useful; nor is any thing lost to the community by the intermission of public industry one day in the week; for in countries tolerably advanced in population, and the arts of civil life, there is always more than enough of human labor. Secondly, Sunday, by suspending many public diversions, and the ordinary rotation of employment, leaves to men of every rank and profession sufficient leisure, and not more than sufficient, both for the external offices of Christianity, and the actual, but equally necessary, duties of religious meditation and enquiry. And thirdly, they whose humanity embraces the whole sensitive creation, will esteem it no inconsiderable recommendation of a weekly return of public rest, that it affords a respite to the toil of brutes.

The uses of this institution, therefore, being to facilitate attendance upon public worship, or to meliorate the condition of the laborious classes of mankind, and, by a general suspension of business and amusement, to invite and enable persons of every description to apply their time and thoughts to subjects pertaining to their salvation, the duty of the day must be violated; first, by all such employments or engagements as hinder our attendance upon public worship, or occupy so much of our time as not to afford sufficient leisure for religious reflection; such are travelling, visiting during the whole day, or employing the time at home in any kind of business that bears no relation to religion. Secondly, by unnecessary encroachments on the rest and liberty which Sunday ought to afford to the inferior orders of the community. Thirdly, by such recreations as are customarily forborne, out of respect to the day; as hunting, shooting, fishing, public diversions, and playing at cards or dice.

SUNDAY SCHOOLS. See EDUCATION.

SUNDEEP ISLE (Somadwipa, or Isle of the Moon), an island in the district of Chittagong, and province of Bengal, which may be estimated at sixteen miles in length, by eight the average breadth. It contains a government establishment for the manufacture of salt, subordinate to the Bulwa and Chittagong agency. A number of Portuguese settled on this coast at the conclusion of the sixteenth century, many of whom entered into the service of the native princes, and obtained grants of land. They were extirpated or expelled from Arracan about A. D. 1607, the few who escaped taking refuge among the islands, where they practised piracy. Futteh Khan, the Mogul governor of Sundep, having attempted to suppress them, was defeated and killed, and his whole fleet captured. On this event the pirates elected for their chief a common sailor, named Sebastian Gonzales, and in 1609 gained possession of Sundep. This chief established an independent principality, his force amounting to 1000 Portuguese, 2000 native troops, 200 cavalry, and eighty vessels of different sizes, well supplied with guns. Soon after he added to his territory the adjacent island of Shahabaspour, and some others. With common prudence his power now might have attained a considerable height and stability, but he soon disgusted his subjects by the brutal tyranny of his government, and rendered the Moguls and Arracaners hostile by the perfidy and cruelty of his conduct. He was finally abandoned by the greater part of his followers, and in 1616 was defeated by the Rajah of Arracan, who conquered Sundep and the other islands. This island continued in possession of these barbarians until A. D. 1666, when Shaista Khan, the Mogul governor of Bengal, having fitted out a fleet at Dacca, despatched it down the Megna to attack Sundep, where the Mughls (so the Arracaners were now called) had erected fortifications, which they defended with great resolution for a considerable time, but were at length all taken or destroyed. Since that period it remained attached to the Mogul government of Bengal, until it devolved, along with that province, to the East India Company.

SUN'DER, *v. a. & n. s.* Сак. гундурян. To part; separate; divide: two.

He breaketh the bow, and cutteth the spear in sunder. *Psalms.*

Vexation almost stops my breath,
That *sundered* friends greet in the hour of death. *Shakspeare.*

She that should all parts to re-union bow,
She that had all magnetic force alone,
To draw and fasten *sundered* parts in one. *Donne.*

It is *sundered* from the main land by a sandy plain. *Carete.*

The enormous weight was cast,
Which Crantor's body *sundered* at the waist. *Dryden.*

Bears, tigers, wolves, the lion's angry brood,
Whom heaven endued with principles of blood,
He wisely *sundered* from the rest, to yell
In forests. *Id.*

Bring me lightning, give me thunder;
—Jove may kill, but ne'er shall *sunder*. *Granville.*

SUNDERBUNDS, a woody tract of country

on the coast of Bengal, being part of the Delta of the Ganges, and extending along the bay about 180 miles. It is in fact a labyrinth of rivers and creeks, all of which are salt, except those that communicate immediately with the principal arm of the Ganges: these numerous natural canals are so disposed as to form a complete inland navigation. In tracing the coast of this Delta, eight openings are found, each of which appears to be the principal mouth of the Ganges. The navigation of the Sunderbunds is effected chiefly by means of the tides, there being two distinct passages; the one named the Southern or Sunderland Passage, and the other the Balliaghaut Passage. The first is the furthest, and leads through the widest and deepest rivers, opening into the Hooghly or Calcutta River, about sixty-five miles below the town. The Balliaghaut Passage opens into a lake on the east side of Calcutta. The navigation by these passages extends more than 200 miles through a thick forest, divided into numberless islands by a multitude of channels, so various in point of width that a vessel has at one time her masts entangled among the branches of trees, and at other times sails on a broadly expanded river, beautifully skirted. The water is every where salt, and almost the whole forest abandoned to wild beasts. But during the dry season the lower shores of these rivers are visited by the salt-makers and woodcutters; while tigers of the most enormous size not only appear on the margin, but frequently swim off to the boats that lie at anchor in the rivers. These waters also swarm with alligators. Throughout the year these passages are open; and, during the season, when the Ganges is low, the whole trade of Bengal (the western districts excepted) passes either by Channel Creek, or by Balliaghaut; but chiefly by the former. The existence of this forest also has always been considered of importance as a strong natural barrier along the southern frontier of Bengal. Great quantities of excellent salt are here manufactured, and esteemed of peculiar sanctity, as being extracted from the Ganges. The woods also present an inexhaustible supply of timber for fuel, boat building, and other purposes. In 1784 the Sunderbunds, Cooch Bahar, and Rangamattay, all nearly waste, according to major Rennell, contained 37,549 square miles.

SUNDERLAND, a sea-port and market-town of Durham, is situate at the mouth of the river Wear, where it falls into the ocean, thirteen miles north-east of Durham, and 276 north of London. The High Street, which is the principal, is nearly a mile in length, running from east to west; the houses in general are well built, and the street in many places thirty yards broad. Parallel with this runs the Lower street, which is very narrow and dirty, and may be called the Wapping of the town, on the bank of the river; but in these, and the numerous narrow lanes connecting the two streets, there have of late years been many improvements, and it is well lighted. Besides an extensive church, at the top of the town, here is a neat built chapel of ease, and several meeting-houses; a dispensary, humane society, charity for decayed seamen, and seamen's widows; besides four good charity schools,

and other benevolent institutions. Here are also a handsome exchange, public library, large assembly room, theatre, commercial bank, &c. The harbour is too shallow for large vessels to take in their lading, so that they are obliged to lie in the open road, and receive their coals by the keels. The entrance of the harbour is defended by a pier projecting about 200 yards, and its mouth by a battery, opposite to which are barracks for 3000 men. The harbour has been further improved by the erection of an elegant light-house.

The trade of Sunderland has been long on the increase: its imports are flour, wines, liquors, timber, iron, flax, &c.: of its exports, coal is the staple article, which alone employs nearly 600 vessels; the other articles are lime, glass, glass bottles, copperas, patent ropes, earthenware, &c.: ship-building is also carried on here. At the extremity of the town, towards Bishopwearmouth, is a bridge over the Wear, built of cast iron, and of a single arch; it is 100 feet high and 236 feet long, so that any vessel that can navigate the depth of water can pass with her top-mast up. This is a borough, governed by a mayor, and returns two members to parliament. Market on Friday. Fairs, May 12th, and October 12th.

SUN-DEW, in botany. See DROSERA.

SUNDIAL, *n. s.* Sun and dial. A marked plate on which the shadow points the hour.

All your graces no more you shall have,
Than a sundial in a grave.

The body, though it really moves, yet, not changing perceivable distance, seems to stand still; as is evident in the shadows of sundials.

SUN-DIAL. See DIAL and DIALLING.

SUNDRY, *adj.* Sax. *runær*. Several; more than one.

Not of one nation was it peopled, but of sundry people of different manners.

That law, which, as it is laid up in the bosom of God, we call eternal, receiveth, according unto the different kind of things which are subject unto it, different and sundry kinds of names.

He caused him to be arrested upon complaint of sundry grievous oppressions.

But, dallying in this place so long why do'st thou dwell,

So many sundry things here having yet to tell?

I have composed sundry collects, as the Adventual, Quadragesimal, Paschal or Pentecostal.

Sundry foes the rural realm surround.

SUN-FISH. See SQUALUS.

SUN-FLOWER, in botany. See HELIANTHUS.

SUN-FLOWER, BASTARD. See HELENIUM.

SUNG. The *pret.* and *part. pass.* of SING, which see.

A larger rock then heaving from the plain,
He whirled it round, it sung across the main.

SUNK. The *pret.* and *part. pass.* of SINK, which see.

We have large caves; the deepest are sunk six hundred fathom, and some digged and made under great hills.

Thus we act, and thus we are,
Or tossed by hope or sunk by care.

His spirit quite *sunk* with those reflections that solitude and disappointment brings, he is utterly undistinguished and forgotten. *Swift.*

SUOVETAURILIA, an ancient Roman sacrifice, so called because it consisted of a pig (*sus*), a sheep or rather ram (*ovis*), and a bull (*taurus*). They were all males, to denote the masculine courage of the Roman people. It was likewise called *solitaurilia*, because the animals offered up were always *solida*, whole or uncut.

SUP, *v. a., v. n., n. s.* Sax. *pupan*; Norman Fr. *souper*; Belg. *soepen*. To drink by mouthfuls; drink by little at a time; to sip: to treat with supper: eat the evening meal: a small draught.

When they had *supped*, they brought Tobias in. *Tobit viii.*

You'll *sup* with me ?

—Anger's my meat; I *sup* upon myself, And so shall starve with feeding.

Shakspeare, Coriolanus.

He's almost *supped*; why have you left the chamber ? *Shakspeare.*

Let what you have within be brought abroad, To *sup* the stranger. *Chapman's Odyssey.*

Tom Thumb had got a little *sup*, And Tomalin scarce kissed the cup. *Drayton.*

'Here's none observes, much less repines, How often this man *sup*s or dines. *Carew.*

To feed my life with: there I'll *sup*

Balm and nectar in my cup. *Crashaw.*

Late returning home, he *supped* at ease. *Dryden.*

A pigeon saw the picture of a glass with water in it, and flew eagerly up to 't for a *sup* to quench her thirst. *L'Estrange.*

We saw it smelling to every thing set in the room; and, when it had smelt to them all, it *supped* up the milk. *Ray.*

The least transgression of your's, if it be only two bits and one *sup* more than your *sup*, is a great debauch. *Swift.*

SUPERABOUND, *v. n.* } Super and a-
SUPERABUNDANCE, *n. s.* } bound. To be ex-
SUPERABUNDANT, *adj.* } uberant; to be stored
SUPERABUNDANTLY, *adv.* } with more than
enough: the noun substantive, adjective, and
adverb, corresponding.

This case returneth again at this time, except the clemency of his majesty *superabound*. *Bacon.*

She *superabounds* with corn, which is quickly convertible to coin. *Hovel.*

The precipitation of the vegetative terrestrial matter at the deluge amongst the sand, was to retrench the luxury and *superabundance* of the productions of the earth. *Woodward.*

Nothing but the uncreated infinite can adequately fill and *superabundantly* satisfy the desire. *Cheyne.*

So much *superabundant* zeal could have no other design than to damp that spirit raised against Wood. *Swift.*

SUPERADD, *v. a.* } Lat. *superaddo*. To
SUPERADDITION, *n. s.* } add over and above;
to join any thing extrinsic: the act of doing so.

The strength of any living creature, in those external motions, is something distinct from and *superadded* unto its natural gravity.

Wilkins's Mathematical Magick.

The fabric of the eye, its safe and useful situation, and the *superaddition* of muscles, are a certain pledge of the existence of God. *More.*

The schools dispute, whether in morals the external action *superadds* any thing of good or evil to the internal elicit act of the will; but certainly the en-

mity of our judgments is wrought up to an high pitch before it rages in an open denial. *South.*

An animal, in the course of hard labour, seems to be nothing but vessels: let the same animal continue long in rest, it will perhaps double its weight and bulk: this *superaddition* is nothing but fat. *Arbutnot.*

SUPERADVENIENT, *adj.* Lat. *superadveniens*. Coming to the increase or assistance of something.

The soul of man may have matter of triumph, when he has done bravely by a *superadvenient* assistance of his God. *More.*

SUPERANNUATE, *v. a. & v. n.* Lat. *superannus*. To impair or disqualify by age or length of life: last beyond the year.

The dying of the roots of plants that are annual, is by the over-expend of the sap into stalk and leaves; which being prevented, they will *superannuate*. *Bacon's Natural History.*

If such depravities be yet alive, deformity need not despair, nor will the eldest hopes be ever *superannuated*. *Brownie.*

When the sacramental test was put in execution, the justices of peace through Ireland, that had laid down their commissions, amounted only to a dozen, and those of the lowest fortune, and some of them *superannuated*. *Swift.*

SUPERB, *adj.* Fr. *superbe*; Lat. *superbus*. Grand; pompous; lofty; august; stately; magnificent.

SUPERBUS (Lat.) the Proud, a nickname of the tyrant Tarquin II, who was deservedly banished Rome, with his wicked family. See **ROME**.

SUPERCARGO, *n. s.* Super and cargo. An officer in the ship whose business is to manage the trade.

I only wear it in a land of Hectors, Thieves, *supercargoes*, sharpers, and directors. *Pope.*

SUPERCELESTIAL, *adj.* Super and celestial. Placed above the firmament.

I dare not think that any *supercelestial* heaven, or whatsoever else, not himself, was increate and eternal. *Raleigh.*

Many were for fetching down I know not what *supercelestial* waters for the purpose.

Woodward's Natural History.

SUPERCILIOUS, *adj.* } From Lat. *super-*
SUPERCILIOUSLY, *adv.* } *cilium*. Haughty;
dogmatical; dictatorial; overbearing: the adverb corresponding.

He, who was a punctual man in point of honour, received this address *superciliously* enough, sent it to the king without performing the least ceremony. *Clarendon.*

Those who are one while courteous, within a small time after are so *supercilious*, fierce, and exceptions, that they are short of the true character of friendship. *South.*

Several *supercilious* criticks will treat an author with the greatest contempt, if he fancies the old Romans wore a girdle. *Addison.*

SUPERCONCEPTION, *n. s.* Super and conception. A conception admitted after another conception.

Those *superconceptions*, where one child was like the father, the other like the adulterer, seem idle.

Broune's Vulgar Errors.

SUPERCONSEQUENCE, *n. s.* Super and consequence. Remote consequence.

Not attaining the deuteroscopy, and second intention of the words, they omit their *superconsequences* and coherences. *Browne.*

SUPERCRES'CENCE, n. s. Lat. *super* and *cresco*. That which grows upon another growing thing.

Wherever it groweth it maintains a regular figure, like other *supercrecences*, and like such as, living upon the stock of others, are termed parasitical plants.

Browne's Vulgar Errours.

SUPEREM'INENCE, n. s. } Latin *super*
SUPEREM'INENCY, } and *emineo*. Un-
SUPEREM'INENT, adj. } common degree
SUPEREM'INENTLY, adv. } of eminence;
 eminence above others though eminent: the ad-
 jective and adverb corresponding.

As humility is in suiters a decent virtue, so the testification thereof by such effectual acknowledgments not only argueth a sound apprehension of his *supereminent* glory and majesty before whom we stand, but putteth also into his hands a kind of pledge or bond for security against our unthankfulness. *Hooker.*

The archbishop of Canterbury, as he is primate over all England and metropolitan, has a *supereminentcy*, and even some power over the archbishop of York. *Ayliffe's Parergon.*

SUPERER'OGATE, v. n. } Lat. *super* and
SUPER'OGATORY, adj. } *erogatio*. To do more than duty requires: performed beyond the strict demands of duty.

Supererogatory services, and too great benefits from subjects to kings, are of dangerous consequence. *Howel.*

So by an abbey's skeleton of late, I heard an echo *supererogate* Through imperfection, and the voice restore, As if she had the hiccup o'er and o'er. *Cleaveland.*

Aristotle acted his own instructions, and his obsequious sectators have *supererogated* in observance. *Glanville's Scepsis.*

There is no such thing as works of *supererogation*; no man can do more than needs, and is his duty to do, by way of preparation for another world. *Tillotson.*

SUPEREROGATION, in theology, is what a man does more than he is commanded to do. The L. nianists stand up strenuously for works of supererogation, and maintain that the observance of evangelical councils is such. By means hereof a stock of merit is laid up, which the church has the disposal of, and which she distributes in indulgences to such as need. This doctrine was first invented towards the close of the twelfth century, and modified and embellished by St. Thomas in the thirteenth: according to which it was pretended that there actually existed an immense treasure of merit, composed of the pious deeds and virtuous actions which the saints had performed beyond what was necessary for their own salvation, and which were therefore applicable to the benefit of others; that the guardian and dispenser of this precious treasure was the Roman pontiff; and that of consequence he was empowered to assign to such as he thought proper a portion of this inexhaustible source of merit, suitable to their respective guilt, and sufficient to deliver them from the punishment due to their crimes. The reformed church do not allow of any work of supererogation; but hold, with the apostles, that when we have done our

best, we are but unprofitable servants. See **SOLIDARIANS.**

SUPEREXALTATION, n. s. Super and exalt. Elevation above the common rate.

In a *superexaltation* of courage, they seem as greedy of death as of victory. *Holiday.*

SUPEREX'CELLENT, adj. Super and excellent. Excellent beyond common degrees of excellence.

We discern not the abuse; suffer him to persuade us that we are as gods, something so *superexcellent*, that all must reverence and adore. *Decay of Piety.*

SUPEREXCRES'CENCE, n. s. Super and excrescence. Something superfluously growing

As the escar separated between the scarifications I rubbed the *superexcrescence* of flesh with the vitriol stone. *Wiseman.*

SUPERFETATE, v. n. } Lat. *super* and
SUPERFETATION, n. s. } *fatus*. To conceive after conception: for the noun substantive see below.

Superfétation must be by abundance of sap in the bough that putteth it forth. *Bacon's Natural History.*

If the *superfétation* be made with considerable intermission, the latter most commonly becomes abortive; for the first being confirmed engrosseth the aiment from the other. *Browne.*

The female brings forth twice in one month, and so is said to *superfetate*; which, saith Aristotle, is because her eggs are hatched in her one after another. *Grew's Museum.*

SUPERFETATION, in midwifery, is a second conception, happening when the mother, already pregnant, conceives of a later coition; so that she bears at once two fœtuses of unequal age and bulk, and is delivered of them at different times. We meet with instances of superfetations in Hippocrates, Aristotle, Du Laurens, &c.; but they are said to be most frequent in hares and swine.

SUPERFICE, n. s. } Fr. *superficie*; Lat.
SUPERFICIAL, adj. } *superficies*. Outside;
SUPERFICIALITY, n. s. } surface: which the
SUPERFICIALLY, adv. } Lat. *superficies* also
SUPERFICIALNESS, n. s. } signifies: superficial
SUPERFICIES. } is, lying on the surface; relating to, or not beyond, the surface: the derivatives all correspond.

He on her *superficies* stretched his line. *Sandys.*
 You have said well;

But on the cause and question now in hand,
 Have glozed but *superficially*.

Shakespeare. Troilus and Cressida.
 This *superficial* tale
 Is but a preface to her worthy praise.

Id. Henry VI.

That, upon the *superficial* ground, heat and moisture cause putrefaction, in England is found not true. *Bacon.*

His eye so *superficially* surveys
 These things, as not to mind from whence they
 grow,

Deep under ground. *Milton's Paradise Lost.*

By these salts the colours of bodies receive degrees of lustre or obscurity, *superficialty* or profundity.

Then if it rise not to the former height
 Of *superficie*, conclude that soil is light. *Dryden.*

A convex mirror makes objects in the middle to come out from the *superficies*: the painter must, in respect of the light and shadows of his figures, give them more relievo. *Id.*

SUPERFICIES, or **SURFACE**, in geometry, is the exterior face of any body. This is considered as having the two dimensions of length and breadth only, but no thickness; and therefore it makes no part of the substance or solid content or matter of the body. The terms or bounds, or extremities, of a superficies, are lines; and superficies may be considered as generated by the motions of lines. Superficies are either rectilinear, curvilinear, plane, concave, or convex. A rectilinear superficies is that which is bounded by right lines. Curvilinear superficies is bounded by curve lines. Plane superficies is that which has no inequality in it, nor risings, nor sinkings, but lies evenly and straight throughout, so that a right line may wholly coincide with it in all parts and directions. Convex superficies is that which is curved and rises outwards. Concave superficies is curved and sinks inward. See **GEOMETRY**.

SUPERFINE', *adj.* Super and fine. Eminently fine.

Some, by this journey of Jason, understand the mystery of the philosopher's stone; to which also other *superfine* chymists draw the twelve labours of Hercules. *L' Etrange.*

If you observe your cyder, by interposing it between a candle and your eye, to be very transparent, it may be called *superfine*. *Mortimer's Husbandry.*

SUPERFLU'ENCE, *n. s.* } Lat. *super* and
SUPERFLU'ITANCE, } *flu.* More than is
SUPERFLU'ITANT, *adj.* } necessary: super-
SUPERFLU'ITY, *n. s.* } fluitance is the act
SUPER'FLUOUS, *adj.* } of flowing above:
SU'PERFLUX, *n. s.* } superfluitant is
 floating above: superfluity, more than enough: superfluous, exuberant; unnecessary: superflux, that which is more than is wanted.

As touching the ministering to the saints, it is *superfluous* to write. *2 Cor. ix. 1.*

I think it *superfluous* to use any words of a subject so praised in itself as it needs no praises. *Sidney.*

When a thing ceaseth to be available unto the end which gave it being, the continuance of it must then appear *superfluous*. *Hooker.*

Having this way eased the church, as they thought, of *superfluity*, they went on till they had plucked up even those things which also had taken a great deal deeper root. *Id.*

Take physick, pomp;
 Expose thyself to feel what wretches feel,
 That thou may'st shake the *superflux* to them. *Shakespeare.*

A proper title of a peace, and purchased
 At a *superfluous* rate. *Id.*

They are as sick that surfeit with too much as they that starve with nothing; therefore it is no mean happiness to be seated in the mean: *superfluity* comes sooner by white hairs, but competency lives longer. *Id.*

A quiet mediocrity is still to be preferred before a troubled *superfluity*. *Suckling.*

The *superfluence* of grace is ordinarily proportioned to the faithful discharge of former trusts, making use of the foregoing sufficient grace. *Hanmond.*

If ye know,
 Why ask ye, and *superfluous* begin
 Your message, like to end as much in vain? *Milton.*
 Spermaceti, which is a *superfluitance* on the sea, is not the sperm of a whale. *Browne's Vulgar Errors.*

Like the sun, let bounty spread her ray,
 And shine that *superfluity* away. *Pope.*

Horace will our *superfluous* branches prune,
 Give us new rules, and set our harps in tune. *Roscommon.*

His conscience cheered him with a life well spent
 His prudence a *superfluous* something lent,
 Which made the poor who took, and poor who gave,
 content. *Harte.*

SUPERFLUOUS INTERVAL, in music, is one that exceeds a true diatonic interval by a semitone minor. See **INTERVAL**.

SUPERGA, a mountain of the north of the Sardinian states, in Piedmont, about five miles from Turin, remarkable for its picturesque scenery, and for the elegance of a church which crowns its summit. This edifice, built by Victor Amadeus, is of a circular form, supported by pillars of beautiful marble, and surmounted by a dome: the altars are decorated with bas-reliefs, and the pavement is of variegated marble. It is the burial place of the royal family, is seen from the surrounding country to a considerable distance, and commands a most delightful view.

SUPERINCUMBENT, *adj.* Lat. *super* and *incumbens*. Lying on the top of something else.

It is sometimes so extremely violent that it forces the *superincumbent* strata; breaks them throughout, and thereby perfectly undermines and ruins their foundations. *Woodward.*

SUPERINDUCE', *v. a.* } Lat. *super* and
SUPERINDUCION' *n. s.* } *indico*. To bring in
 as an addition to something else: the act of so doing.

To *superinduce* any virtue upon a person, take the living creature in which that virtue is most eminent. *Bacon.*

Custom and corruption *superinduce* upon us a kind of necessity of going on as we began. *L' Etrange.*

Father is a notion *superinduced* to the substance of man, and refers only to an act of that thing called man, whereby he contributed to the generation of one of his own kind, let man be what it will. *Locke.*

In children, savages, and ill-natured people, learning not having cast their native thoughts into new moulds, nor, by *superinducing* foreign doctrines, confounded those fair characters nature had written, their innate notions might lie open. *Id.*

Relation is not contained in the real existence of things, but something extraneous and *superinduced*. *Id.*

Long custom of sinning *superinduces* upon the soul new and absurd desires, like the distemper of the soul, feeding only upon filth and corruption. *South.*

A good inclination is but the first rude draught of virtue; the *superinduction* of ill habits quickly defaces it. *Id.*

SUPERINTEND', *v. a.* } Super and in-
SUPERINTEND'ENCE, *n. s.* } tend. To over-
SUPERINTEND'ENCY, } see; overlook; to
SUPERINTEND'ENT, } to take care of
 others with authority: the derivatives correspond.

The king will appoint a council, who may *superintend* the works of this nature, and regulate what concerns the colonies. *Bacon's Advice to Villiers.*

Next to Brama, one Deundre is the *superintendent* deity, who hath many more under him. *Stillingfleet.*

Such an universal *superintendency* has the eye and hand of Providence over all, even the most minute and inconsiderable things. *South.*

The world pays a natural veneration to men of virtue, and rejoice to see themselves conducted by those who act under the care of a Supreme Being.

and who think themselves accountable to the great Judge and Superintendent of human affairs. Addison.

The divine Providence, which hath a visible respect to the being of every man, is yet more observable in its *superintendency* over societies. Grew.

This argues design, and a *superintending* wisdom, power and providence in this special business of food.

Derham.

An admirable indication of the divine *superintendence* and management. Id.

Angels, good or bad, must be furnished with prodigious knowledge, to oversee Persia and Grecia of old; or if any such *superintend* the affairs of Great Britain now. Watts.

SUPERINTENDENT, or SUPERINTENDANT, denotes an ecclesiastical superior in several reformed churches where episcopacy is not admitted; particularly among the Lutherans in Germany, and the Calvinists in some other places. The superintendent is similar to a bishop; only his power is somewhat more restrained than that of the diocesan bishops. He is the chief pastor, and has the direction of all the inferior pastors within his district or diocese. In Germany they had formerly superintendents general, who were superior to the ordinary superintendents. These, in reality, were archbishops; but the dignity is sunk into disuse; and at present none but the superintendent of Wirtemberg assumes the quality of superintendent general.

SUPERIOR, adj. & n. s. } Fr. *superieur*;
SUPERIORITY, n. s. } Lat. *superior*.

Higher; upper; greater in dignity or excellence; preferable or preferred; above; unaffected; free from emotion or censure: a more excellent or more skilled person: superiority is, exaltation; pre-eminence.

In commending another, you do yourself right; for he that you commend is either *superiour* to you in that you commend, or inferior: if he be inferior, if he be to be commended, you much more: if he be *superior*, if he be not to be commended, you much less glorious. Bacon.

Although *superior* to the people, yet not *superior* to their own voluntary engagements once passed from them. Taylor.

Here passion first I felt,
 Commotion strange! in all enjoyments else
Superior and unmoved. Milton.

Bellarmino makes the formal act of adoration to be subjection to a *superiour*; but he makes the mere apprehension of excellency to include the formal reason of it; whereas, mere excellency without *superiority* doth not require any subjection, but only estimation. Stillingfleet.

Heaven takes part with the oppressed, and tyrants are upon their behaviour to a *superiour* power. L'Estrange.

Superior beings above us, who enjoy perfect happiness, are more steadily determined in their choice of good than we, and yet they are not less happy or less free than we are. Locke.

The person who advises, does in that particular exercise a *superiority* over us, thinking us defective in our conduct or understanding. Addison's Spectator.

There is not in earth a spectacle more worthy than a great man *superiour* to his sufferings. Id.

Those under the great officers of state have more frequent opportunities for the exercise of benevolence than their *superiors*. Id.

By the refraction of the second prism, the breadth

of the image was not increased; but its *superior* part which in the first prism suffered the greater refraction, and appeared violet and blue, did again in the second prism suffer a greater refraction than its inferior part, which appeared red and yellow. Newton's Opticks.

He laughs at men of far *superior* understanding to his, for not being as well dressed as himself. Swift.

SUPERIOR LAKE, or UPPER LAKE, the largest lake in North America, and supposed to be the largest body of fresh water in the world, being computed 1500 miles in its circle. The boundary line between the United States and Upper Canada passes through the central part of it. The surrounding coast is rocky and uneven. There are in it many islands; two of them very considerable; one of them, Isle Royal, is not less than 100 miles in length, and in some places forty broad. The lake abounds with fish, particularly trout and sturgeon, which may be caught at almost any season in the greatest abundance. The trout in general weigh about twelve pounds, but some are caught that exceed fifty. This lake is as much affected by storms as the Atlantic Ocean; the waves run as high, and are equally dangerous to ships. It discharges its waters from the south-east corner, through the straits of St. Mary. See AMERICA NORTH.

SUPERLATIVE, adj. } Fr. *superlatif*;
SUPERLATIVELY, adv. } Lat. *superlativus*.

SUPERLATIVENESS, n. s. } Implies or expressing the highest degree; rising in the highest degree: the adverb and both the noun substantives correspond.

The high court of parliament in England is *superlative*. Bacon's Advice to Villiers.

Martyrdoms I reckon amongst miracles; because they seem to exceed the strength of human nature; and I may do the like of *superlative* and admirable holiness. Bacon.

I shall not speak *superlatively* of them; but that I may truly say, they are second to none in the Christian world. Id.

There are words that as much raise a style as others can depress it; *superlation* and overmuchness amplifies: it may be above faith but not above a mean. Ben Jonson.

It is an usual way to give the *superlative* unto things of eminence; and, when a thing is very great, presently to define it to be the greatest of all. Broune's Vulgar Errors.

The generality of its reception is with many the persuading argument of its *superlative* desert; and common judges measure excellency by numbers. Glanville.

Ingratitude and compassion never cohabit in the same breast; which shews the *superlative* malignity of this vice, and the baseness of the mind in which it dwells. South.

Tiberius was bad enough in his youth; but *superlatively* and monstrously so in his old age. Id.

The Supreme Being is a spirit most excellently glorious, *superlatively* powerful, wise and good, Creator of all things. Bertley.

Some have a violent and turgid manner of talking and thinking; they are always in extremes, and pronounce concerning every thing in the *superlative*. Watts.

SUPERLUNAR, adj. Lat. *super* and *luna*. Not sublunary; placed above the moon; not of this world.

The mind, in metaphysics, at a loss,
May wander in a wilderness of moss ;
The head that turns at *supertunar* things,
Poised with a tail, may steer on Wilkins' wings.

Pope.

SUPERNA, in Hindoo mythology, is a name of a celebrated bird in the legends of the east, usually employed to carry the person of the god Vishnu. Most of the Hindoo deities have animals assigned them as vehicles for journeying. They are called in Sanscrit *van*, or *vahan* ; one of the commonest names of *Superna* is *Garuda*, sometimes pronounced *Garoor*, by which a large species of falcon, well known in all parts of India, is also called. The English usually style it the *Brahmany kite*; it being held in veneration by many Hindoos, who very much dislike having it killed. In this there is utility, as well as superstition; for the bird in question is very useful, in concert with the vulture, in devouring carrion, and performing the office of scavenger.

The mythological *Garuda* is variously portrayed, as a man with the beak and wings of an eagle, painted red, green, or blue. He is also frequently seen in casts; and as sculptured in the cavern temple at *Elephanta*, with *Vishnu*, is seated straddling, rather ridiculously in our eyes, on his shoulders; *Garuda* holding by both hands on *Vishnu's* ancles. Wherever he appears in this cave his projecting nose or beak has been broken off, as it is said, and with reason, by the iconoclastic fury of the Portuguese, while *Bombay* and its contiguous islands, including that called by us *Elephanta*, were in their possession.

The birth, life, and exploits of *Garuda*, are constantly referred to in Hindoo writings. One of the *Puranas* is called after him, *Garuda Purana*. *Vishnu* being the sun, *Garuda* seems, as his apparent vehicle, and in some points of family and character, to be a personification of the sky. His younger brother is named *Aruna*, and is the driver or precursor of the glorious car of *Surya*, or the sun; hence corresponding perhaps with the *Aurora*, or dawn, of western fable; as well as carrying *Vishnu*, and his consort *Lakshmi*. *Garuda* is seen also flying through the air with *Rama* and *Sita*, and sometimes with *Krishna*, on his back. But there are representations by sectaries of these several gods, who, each adoring the incarnation as the deity, array the object of their adoration in the attributes of the archetype.

Garuda is stated to have married a beautiful woman, when the tribe of serpents, alarmed at this marriage, lest the offspring should inherit he propensities of the fire, waged fierce war against him; but he destroyed them all, save one, which he placed in an ornament about his neck. In several parts of the *Elephanta* cave *Garuda* is seen with this appendage; and, on very ancient Hindoo coins and medals, he has snakes and elephants in his talons and beaks: for he is sometimes spread and double-headed, like the eagle of Prussia. *Garuda* had a son of some note, named *Sunabha*; and a daughter of surprising beauty, named *Su-mati*, who was espoused by *Sagara*, or the sea. If we recollect

the surmise that *Garuda*, or *Superna*, as the vehicle of *Vishnu*, a type of the aqueous element, is a personification of the sky or visible firmament, we may discover some connexion in the allegory of an alliance between his descendant and the sea. The beautiful maiden (the meaning of her name, *Su-mati*) thus allied, became wonderfully prolific: she brought forth (if the Hindoo romantic language be rightly construed) a gourd, whence issued 60,000 male children. The author of the Hindoo Pantheon, in his account of *Garuda*, notices the extensive prevalence of serpentine forms in the mythological machinery of Egypt and Greece, as well as in India.

SUPERNAL, *adj.* Lat. *supernus*. Having a higher position; locally above us.

That *supernal* Judge that stirs good thoughts
In any breast of strong authority,
To look into the blots and stains of right.

Shakspeare.

By heaven and earth was meant the solid matter and substance, as well of all the heavens and orbs *supernal*, as of the globe of the earth, and waters which covered it.

Raleigh.

He with frequent intercourse
Thither will send his winged messengers,
On errands of *supernal* grace.

Milton.

SUPERNATANT, *adj.* } Lat. *supernatans*.
SUPERNATA'TION, *n. s.* } Swimming above:
the act of swimming above.

Touching the *supernatation* of bodies, take of aquafortis two ounces, of quicksilver two drams, the dissolution will not bear a flint as big as a nutmeg.

Bacon's Natural History.

Bodies are differenced by *supernatation*, as floating on water; for chrysal will sink in water, as carrying in its own bulk a greater ponderosity than the space of any water it doth occupy; and will therefore only swim in molten metal and quicksilver.

Browne's Vulgar Errors.

Whilst the substance continued fluid, I could shake it with the *supernatant* menstruum, without making between them any true union.

Boyle.

SUPERNATURAL, *adj.* Lat. *super* and *natura*. Being above the powers of nature.

There resteth either no way unto salvation, or, if any, then surely a way which is *supernatural*, a way which could never have entered into the heart of a man, as much as once to conceive or imagine, if God himself had not revealed it extraordinarily; for which cause we term it the mystery or secret way of salvation.

Hooker.

No man can give any rational account how it is possible that such a general flood should come, by any natural means. And, if it be *supernatural*, that grants the thing I am proving, namely, such a supreme being as can alter the course of nature.

Wilkins.

The understanding is secured by the perfection of its own nature, or by *supernatural* assistance.

Tillotson.

What mists of providence are these,
Through which we cannot see?

So saints by *supernatural* power set free
Are left at last in martyrdom to die.

Dryden.

The Son of God came to do every thing in miracle to love *supernaturally*, and to pardon infinitely, and even to lay down the Sovereign while he assumed the Saviour.

South.

SUPERNUMERARY, *adj.* Fr. *supernume-*

raire; Lat. *super* and *numerus*. Being above a stated, a necessary, a usual, or a round number.

Well if thrown out, as *supernumerary* To my just number found. *Milton's Paradise Lost*.
In sixty-three years there may be lost eighteen days, omitting the intercalation of one day every fourth year, allowed for this quadrant or six hours *supernumerary*. *Browne*.

Besides occasional and *supernumerary* addresses, Hammond's certain perpetual returns exceeded David's seven times a-day. *Fell*.
The odd or *supernumerary* six hours are not accounted in the three years after the leap year. *Holder*.

The produce of this tax is adequate to the services for which it is designed, and the additional tax is proportioned to the *supernumerary* expense this year. *Addison's Freeholder*.

A *supernumerary* canon is one who does not receive any of the profits or emoluments of the church, but only lives and serves there on a future expectation of some prebend. *Ayliffe*.

Antiochus began to augment his fleet; but the Roman senate ordered his *supernumerary* vessels to be burnt. *Arbutnot*.

SUPERPARTICULAR PROPORTION, or ratio, is that in which the greater term exceeds the less by unit or 1. As the ratio of 1 to 2, or 2 to 3, or 3 to 4, &c.

SUPERPARTIENT (from *super* and *part*), containing more than a division.

SUPERPARTIENT PROPORTION, or ratio, is when the greater term contains the less term once, and leaves some number greater than one remaining. As the ratio

of 3 to 5, which is equal to that of 1 to $\frac{5}{3}$;
of 7 to 10, which is equal to that of 1 to $\frac{10}{7}$, &c.

SUPERPLANT, *n. s.* *Super* and *plant*. A plant growing upon another plant.

No *superplant* is a formed plant but mistletoe.

Bacon.

SUPERPLUSAGE, *n. s.* Lat. *super* and *plus*. Something more than enough.

After this there yet remained a *superplusage* for the assistance of the neighbouring parishes. *Fell*.

SUPERPROPORTION, *n. s.* Lat. *super* and *proportio*. Overplus of proportion.

No defect of velocity, which requires as great a *superproportion* in the cause, can be overcome in an instant. *Digby*.

SUPERPURGATION, *n. s.* Fr. *superpurgation*; *super* and *purgation*. More purgation than enough.

There happening a *superpurgation*, he declined the repeating of that purge. *Wiseman's Surgery*.

SUPERREFLEXION, *n. s.* *Super* and *reflexion*. Reflection of an image reflected.

Place one glass before and another behind, you shall see the glass behind with the image within the glass before, and again the glass before in that, and divers such *superreflexions*, till the species speciei at last die. *Bacon's Natural History*.

SUPERSALENCY, *n. s.* Lat. *super* and *salio*. Better written *supersiliency*. The act of leaping upon any thing.

Their coition is by *supersaliency*, like that of horses.

Browne.

To **SUPERSATURATE**, in chemistry, to saturate a basis with excess of acid. See **SALT**.

SUPERSCRIBE, *v. a.* } Lat. *super* and
SUPERSCRPTION, *n. s.* } *scribo*. To inscribe upon the top or outside: the noun substantive corresponding.

Read me the *superscription* of these letters; I know not which is which. *Shakespeare. Timon*.

No *superscriptions* of fame,
Of honour or good name. *Suckling*.

I learn of my experience, not by talk,
How counterfeit a coin they are who friends
Bear in their *superscription*; in prosperous days
They swarm, but in adverse withdraw their head. *Milton*.

It is enough her stone
May honoured be with *superscription*
Of the sole lady, who had power to move
The great Northumberland. *Waller*.

Fabretti and others believe, that by the two Fortunes were only meant in general the goddess who sent prosperity or afflictions, and produce in their behalf an ancient monument, *superscribed*. *Addison*.

SUPERSEDE', *v. a.* } Lat. *super* and *sedeo*.
SUPERSEDEAS, *n. s.* } To make void or inefficacious by superior power; to set aside: for supersedeas see below.

The far distance of this county from the court hath afforded it a *supersedeas* from takers and purveyors. *Carew*.

Passion is the drunkenness of the mind, and therefore in its present workings not controulable by reason, for as much as the proper effect of it is, for the time, to *supersede* the workings of reason. *South*.

In this genuine acceptance of chance, nothing is supposed that can *supersede* the known laws of natural motion. *Bentley*.

SUPERSEDEAS, in English law, is a writ that lies in a great many cases; and signifies in general a command to stay some ordinary proceedings at law, on good cause shown. It is used for the staying of an execution, after a writ of error is allowed and bail put in: but no *supersedeas* can be made out on bringing writ of error, till bail is given, where there is judgment upon verdict, or by default, in debt. Nor in actions for tithes, promises for payment of money, trover, covenant, detinue, and trespass: stat. 13 Car. II. st. 2, c. 2, and execution shall not be staid in any judgment after verdict (except in the case of executors) by writ of error or *supersedeas* thereon, unless bail be put in.—Stat. 16 and 17, Car. II, c. 8, § 3.

A writ of error is said to be in judgment of law a *supersedeas*, until the errors are examined, &c., that is to the execution; not to action of debt on the judgment at law. From the time of the allowance, a writ of error is a *supersedeas*: and, if the party had notice of it before the allowance, it is a *supersedeas* from the time of such notice; but this must be where execution is not executed, or begun to be executed. Where a first writ of error abates, or is put an end to by the act of the plaintiff in error, a second writ of error brought in the same court is not a *supersedeas* of execution as the first is: and execution may then be sued out without leave of the court. But in error of matter of fact *coram vobis*, which is not within the statutes requiring bail in error, the writ of error is or is not a *supersedeas* according to circumstances; and the court must be moved for leave

to sue out executions pending it.—8 East's Rep. 412. If, before execution, the defendant bring a writ of error, and the sheriff will execute a fieri facias and levy the money, the court will award a supersedeas, quia erroneè emanavit, and to have restitution of the money.—Stile 414. After an execution, there was a supersedeas, quia executio improvidè emanavit, &c., issued; and, there being no clause of restitution in the supersedeas, it was insisted that the execution was executed before the supersedeas awarded, and that a faulty supersedeas is no supersedeas; but the court ordered another supersedeas, with a clause of restitution.—Moor. 466.

A supersedeas, quia erroneè emanavit, lies to restore a possession, after an habere facias seisinam, when sued out erroneously; so of a supersedeas after execution upon a capias subsatisfaciendi, if it be immediately delivered to the sheriff. It appearing from affidavit that there were two writs of execution executed upon one judgment, the party moved for a supersedeas, because there cannot be two such executions, but where the plaintiff is hindered either by the death of the defendant, or by some act in law, that he can have no benefit of the first; and so it was adjudged.—Stile 255. A supersedeas is grantable to a sheriff to stay the return of an habeas corpora; and if he return it afterwards, and the parties proceed to trial, it is error; and so are all the proceedings in an inferior court, after an habeas corpora delivered, unless a procedendo is awarded, in which case a supersedeas is not to be granted.—Cro. Car. 43. 350.

When a certiorari is delivered, it is a supersedeas to inferior courts below; and, being allowed, all their proceedings afterwards are erroneous; and they may be punished. If a sheriff holds plea of 40s. debt in his county court, the defendant may sue forth a supersedeas, that he do not proceed, &c. Or, after judgment, he may have a supersedeas directed to the sheriff, requiring him not to award execution upon such judgment; and upon that an alias, a pluries, and an attachment, &c.—New Nat. Br. 432. Supersedeas may be granted by the court for setting aside an erroneous judicial process, &c. Also a prisoner may be discharged by supersedeas; as a person is imprisoned by the king's writ, so he is to be set at liberty: and a supersedeas is as good a cause to discharge a person, as the first process is to arrest him.—Finch. 453: Cro. Jac. 379. If a privileged person is sued in any jurisdiction foreign to his privilege, he may bring his supersedeas.—Vaugh. 155. It is false imprisonment to detain a man in custody after a supersedeas delivered; for the supersedeas is to be obeyed; and in such case it is a new caption without any cause.—2 Cro. 379. There is a supersedeas where an audita querela is sued; and, out of the chancery, to set a person at liberty, taken upon an exigent, on giving security to appear, &c. And in cases of surety of the peace and good behaviour, where a person is already bound to the peace in the chancery, &c.—New Nat. Br. 524, 529, 532. So where a warrant issues against a man, on an indictment found against him, for a misde-

meanor, or other bailable offence, and he, having notice of it, does, before caption, duly put in bail, to appear and traverse the indictment, &c., he is entitled to a supersedeas, to prevent a caption.

SUPERSEVICEABLE, *adj.* Super and serviceable. Over officious; more than is necessary or required.

A glass-gazing *superserviceable* finical rogue.

Shakspeare.

SUPERSTITION, *n. s.* } Fr. *superstition*;

SUPERSTITIOUS, *adj.* } Lat. *superstitio*.

SUPERSTITIOUSLY, *adv.* } Unnecessary fear or scruples in religion; observance of unnecessary and uncommanded rites or practises; religion without morality: addicted to superstition: the adverb corresponds with the adjective.

They had certain questions against him of their own *superstition*. *Acts xxv. 19.*

At the kindling of the fire, and lighting of candles, they say certain prayers, and use some other *superstitious* rites, which shew that they honour the fire and the light. *Spenser.*

Have I

Been out of fondness *superstitious* to him?

And am I thus rewarded? *Shakspeare. Henry VIII.*

There reigned in this island a king, whose memory of all others we most adore; not *superstitiously*, but as a divine instrument. *Bacon.*

Nature's own work it seemed, nature taught art,

And, to a *superstitious* eye, the haunt

Of wood-gods and wood-nymphs. *Milton.*

A rev'rent fear, such *superstition* reigns

Among the rude, ev'n then possessed the swains. *Dryden.*

A venerable wood,

Where rights divine were paid, whose holy air

Was kept and cut with *superstitious* care. *Id.*

Neither of these methods should be too scrupulously and *superstitiously* pursued. *Watts's Logic.*

If we had a religion that consisted in absurd *superstitutions*, that had no regard to the perfection of our nature, people might well be glad to have some part of their life excused from it. *Law.*

SUPERSTITION is a word that has been used so indefinitely that it is difficult to determine its precise meaning. From its resemblance in sound to the Latin word *superstes*, 'a survivor,' it is evidently derived from it, and different attempts have been made to trace their connexion in signification. Balbus, in the dialogue *De Natura Deorum* of Cicero, says, that they who prayed and sacrificed whole days that their children might survive them, were called *superstitious*. Lactantius censures this etymology, and says they were not called *superstitious* who wished that their children might survive them (for this we all wish), but because they who survived their parents worshipped their images. Others again say that *superstition* is derived from *superstes*, because it consisted in considering the dead as if they were alive. But these etymologies are conjectural and trifling. A more probable etymology may be traced from the primitive words, *super*, above, and *sto*, I stand; for the *superstitious* in all ages and religions flatter themselves that they stand superior to the rest of mankind in holiness. *Superstition* is a word of a very extensive signification. We apply it to the idolatry of the heathens; we apply it also to the Jews, who made the will of God of no effect by

their traditions, and substituted ceremonies in place of the religion of their fathers. We say also that Christians are guilty of superstition; the Roman Catholics, who believe in transubstantiation and in the efficacy of prayers to saints; and those Protestants who esteem baptism and the Lord's supper, and the punctual performance of other ceremonies, without regard to morality, as sufficient for salvation. Those persons also are reckoned superstitious who believe, without evidence, that prophecies are still uttered by divine inspiration, and that miracles are still performed. The word is also extended to those who believe in witchcraft, magic, and apparitions, or that the divine will is declared by omens or augury; that the fortune of individuals can be affected by things indifferent, by things deemed lucky or unlucky, or that diseases can be cured by words, charms, and incantations. Through all these various superstitions, there runs one general idea, the belief of what is false and contrary to reason. But this does not prove that whatever is false and contrary to reason may be denominated superstition. It is false and irrational to say that there ever lived on earth a race of men who walked on one leg, and had their eyes in their breast; or that there were giants ninety feet high: yet we should only call the man who believes these chimeras credulous. Superstition has always a reference to God, to religion, or to beings superior to man. We do not however distinguish all false and irrational opinions in religion by the name of superstition. We do not, for instance, apply this name to the opinions which some of the ancients entertained, that God is the soul of the world, and that men are only portions of him separated for a time, or that the soul after death lives successively in different bodies. Superstition implies ignorance of the moral attributes of God; we never say a man is superstitious for entertaining erroneous opinions of the attributes of God. Some Socinians have denied the prescience of God; and M. La Metherie has not only rejected the belief that he is a spirit, but has presumed to say that he is composed of a species of crystals! The first of these opinions discovers very imperfect ideas of God, and the second is the height of impiety and absurdity; yet the Socinians are not accused of superstition, nor can this French philosopher be suspected of it. Superstition has sometimes been called the opposite of infidelity, for it always includes the idea of credulity. It consists not in falsely denying that God possesses any particular moral attributes, but in believing more than what is true concerning them; in forming mean unworthy ideas of them; in supposing that he is guided by passion like mankind, and enjoins upon his creatures commandments which are irrational and absurd. As all superstition arises from ignorance and credulity in the understanding, so it has also a seat in the passions. Fear has been commonly considered as the passion of the human mind from which it chiefly derives its origin; and there is no doubt that more superstition has arisen from fear, united with ignorance and credulity, than from any other passion. Yet we cannot exclude all other passions. We cannot account for the su-

perstition of the Egyptians, without supposing that much of it arose from gratitude. They worshipped the Nile, because it distributed fertility and abundance over the land of Egypt; and they worshipped some animals, because they prevented the increase of other animals which were noxious. Thus they adored the ibis, because it destroyed the eggs of the crocodile. In a word, superstition respects God and beings superior to man, and extends to our religious opinions, worship, and practices; and may be defined absurd opinions and actions arising from mean and defective ideas of the moral attributes of God. Superstition involves the idea of a blameable inattention to reason, or a credulity arising from an indolence of understanding. We generally make a distinction between the imperfect opinions which a savage, from his situation, forms of the attributes of God, and those which civilized nations entertain. We ascribe the ignorance of the savage to his situation; but we call the Roman Catholic superstitious, and we blame him for not having those just ideas of God which he might obtain from his Bible, by the exercise of his understanding. Superstition then does not originate so much from the natural weakness of the human understanding, as from a misapplication or a neglect of it. We cannot therefore with propriety apply the term superstition to polytheism; for what all the ancient philosophers, after much study and reflection, concluded to be true, could never proceed from credulity and inattention, but from their situation. We very properly, however, call idolatry by the name of superstition; because there is no man so devoid of understanding as not to be capable of discovering that a piece of metal, or wood, or stone, can neither hear nor answer petitions. Superstition was a name which the ancient philosophers gave to those who entertained mean opinions of the gods, or did foolish things to obtain their favor. Theophrastus gives a most ridiculous picture of a superstitious pagan, and of the various whimsical ceremonies performed by such persons to prevent mischief, and to avert the wrath of the gods. The superstitious opinions and practices among Jews and Christians have all equally arisen from mean and absurd ideas of the moral attributes of God; for they have generally entertained noble opinions of his natural attributes. The Jews considered God as a partial Being, who had a predilection for their nation in preference to all others, and preferred external homage and ceremony to moral purity. If the Roman Catholics think consistently, they must esteem God as a Being who can be prevailed upon by the importunity of a dead man to assist another, or as a Being whose patience would be fatigued with hearing prayers constantly. Hence their practice of praying to saints. They consider a strict adherence to a variety of ceremonies, to forms, to pomp, and show, as essential to the worship of God: this is treating God as a vain glorious Being. They thought it their duty to extirpate heretics: this was supposing God a cruel and revengeful Being. Even among Protestants, a great deal of superstition still remains; many, like the Jews, considering God, as partial to

their own peculiar sect, and as reprobating the rest of mankind. Besides those superstitious opinions and practices which entirely respect our duty to God, there are others which may be termed vulgar superstitions. These also arise from imperfect and mean ideas of the moral attributes of God. To believe vulgar prophecies, which are always the effusions of enthusiasm or knavery, is to suppose that God, who has drawn a veil over futurity, and only delivers prophecies to accomplish some great moral purpose, sometimes gives them for no purpose at all, or to gratify idle curiosity.

The belief of witchcraft, of apparitions, and the second sight, may be resolved into the same principle. To suppose that God would communicate the power of doing mischief, and of controlling his laws, to any being, merely for gratifying their own passions, is believing what is unworthy of God. The belief of apparitions is equally inconstant with the goodness of God. See SPECTRE. The same objection rises against the second sight, and may be extended to omens, astrology, things lucky and unlucky, fortune-telling, &c. A judicious history of superstition would exhibit the human character in a remarkable point of view. Superstition is most prevalent among men of weak and uncultivated minds; it is more frequent in the female sex than among men; for this reason, that by their education they have less opportunity of improving their minds. It also, for the same reason, abounds more in the rude than in the refined stages of society. It gained admission into the science of medicine at an early period. He who was endowed with superior genius and knowledge was reckoned a magician. Dr. Bartolo was seized by the inquisition at Rome, in the seventeenth century, because he unexpectedly cured a nobleman of the gout. Diseases were imputed to fascination, and hundreds of poor wretches were dragged to the stake for being accessory to them. Mercatus, physician to Philip II. of Spain, a writer of uncommon accuracy and information, appears strongly inclined to deny the existence of fasciatory diseases; but he is constrained to acknowledge them for two reasons; 1st, Because the inquisition had decided in favor of their reality; 2dly, Because he had seen a very beautiful woman break a steel mirror to pieces, and blast some trees by a single glance of her eyes! As the opinions concerning the cause of diseases were superstitious, those concerning the method of curing them were not less so. In the *Odyssey* we read of a cure performed by a song. Josephus relates that he saw a certain Jew, named Eleazor, draw the devil out of an old woman's nostrils by the application of Solomon's seal to her nose in the presence of Vespasian. Many different kinds of applications were used for expelling the devil. Flagellation sometimes succeeded admirably. Dr. Mynsight cured several bewitched persons with a plaster of assafœtida. Nor was it only in medicine these superstitious opinions were entertained; they prevailed also in natural philosophy. The pernicious effects in mines, which we know now are occasioned by noxious air, were confidently imputed to the demons of the mine. Even Van Helmont,

Bodinus, Strozza, and Luther, attributed thunder and meteors to the devil. Chemists were employed for centuries in search of the philosopher's stone, with which they were to do miracles. It was a common question among philosophers, in the seventeenth century, whether the imagination could move external objects? A question generally decided in the affirmative! Though superstition be generally the mark of a weak mind, such is the infirmity of human nature that we find many instances of it among men of the most sublime genius and most enlightened minds. Socrates believed that he was guided by a demon. Lord Verulam believed in witchcraft; and relates that he was cured of warts by rubbing them with a piece of lard with the skin on, and then nailing it with the fat towards the sun on the post of a chamber window. Henry the Great was rendered very uneasy, by some prophecies of his assassination before it happened; but Julius Cæsar neither believed his wife's dreams, nor the augur's prediction, by which excess of courage he lost his life, and thus both were fulfilled. What say infidels to this? See ROME. Superstition would have saved Cæsar. The enlightened Cudworth defended prophecies in general, and called those who opposed the belief of witchcraft by the name of atheists; and the predictions of Rice Evans have been supported in the present century by the celebrated names of Warburton and Jortin. Dr. Hoffman, the father of the Modern Theory and Practice of Medicine, in a dissertation published in the large edition of his works in 1747, says that the devil can raise storms, produce insects, and act upon the animal spirits and imagination; and, in fine, that he is an excellent optician and natural philosopher, on account of his long experience. Dr. Johnson, the leviathan of literature, believed in the SECOND SIGHT. See that article. With respect to the effects of superstition on the human mind, they are indeed deplorable. It chains down the understanding, sinks it into the most abject and sordid state, and keeps it under the dominion of fear, and sometimes of cruelty. The Christian religion gave a violent shock to the heathen superstition; the Reformation in a great measure demolished the superstition of the church of Rome; and the superstition which remained among protestants after their separation from that church has been gradually yielding to the influence of enlightened reason, or to the bold and daring attacks of infidelity and deism. We behold the prospect of its ruins with pleasure, and thank the deists for their zeal; but it is from the firm hope that the religion of Jesus will arise in all its beauty and simple majesty, and be admired and respected as it deserves; for, mean and contemptible as superstition certainly is, we would rather see men do what they reckon their duty from superstitious principles, than see anarchy and vice prevail, even though attended with all the knowledge and liberality of sentiment which deism and infidelity can inspire.

SUPERSTRAIN, *v. a.* Super and strain. To strain beyond the just stretch.

In the straining of a string, the farther it is strained, the less *superstraining* goeth to a note.

BACON.

SUPERSTRUCT, *v. a.* } Lat. *superstruo*,
SUPERSTRUCTION, *n. s.* } *superstructus*. To
SUPERSTRUCTIVE, *adj.* } build upon any
SUPERSTRUCTURE, *n. s.* } thing : both the
 noun substantives signify that which is so built :
 superstructive, built upon something else.

This is the only proper basis on which to *superstruct* first innocency, and then virtue.

Decay of Piety.

Two notions of fundamentals may be conceived ; one signifying that whereon our eternal bliss is immediately *superstructed*, the other whereon our obedience to the faith of Christ is founded. *Hammond.*

He that is so sure of his particular election, as to resolve he can never fall, must necessarily resolve, that what were drunkenness in another is not so in him ; and nothing but the removing his fundamental error can rescue him from the *superstructive*, be it never so gross. *Hammond.*

I want not to improve the honor of the living by impairing that of the dead ; and my own profession hath taught me not to erect new *superstructures* upon an old ruin. *Denham.*

Purgatory was not known in the primitive church, and is a *superstructure* upon the Christian religion. *Tillotson.*

You have added to your natural endowments the *superstructures* of study. *Dryden.*

He who builds upon the present, builds upon the narrow compass of a point ; and, where the foundation is so narrow, the *superstructure* cannot be high and strong too. *South.*

SUPERVENE' , *v. n.* Lat. *supervenio*. To come as an extraneous addition.

That branch of belief was in him *supervenient* to Christian practice, and not all Christian practice built on that. *Hammond.*

If it were unjust to murder John, the *supervenient* oath did not extenuate the fact, or oblige the juror into it. *Browne.*

His good-will, when placed on any, was so fixed and rooted, that even *supervening* vice, to which he had the greatest detestation imaginable, could not easily remove it. *Fell.*

Such a mutual gravitation can never *supervene* to matter, unless impressed by a divine power. *Bentley.*

SUPERVISE' , *v. a.* Lat. *super* and *visus*. To overlook ; to oversee ; to intend.

How satisfied, my lord !

Would you be *supervisor*, grossly gape on ?

Shakspeare.

I am informed of the author and *supervisors* of this pamphlet. *Dryden.*

Mr. Bayle speaks of the vexation of the *supervising* of the press, in terms so feeling that they move compassion. *Congreve.*

A *supervisor* may signify an overseer of the poor, an inspector of the customs, a surveyor of the highways, a *supervisor* of the excise. *Watt's Logick.*

SUPERVIVE' , *v. n.* Latin *super* and *vivo*. To overlive ; outlive.

Upon what principle can the soul be imagined to be naturally mortal, or what revolutions in nature will it not be able to resist and *supervive* ? *Clarke.*

SUPERUS FLOS. See **BOTANY**, Glossary.

SUPINATION, in anatomy, the action of a supinator muscle, or the motion whereby it turns the hand so as that the palm is lifted up towards heaven.

SUPINE, *adj.* & *n. s.* } Lat. *supinus*. Ly-
SUPINELY, *adv.* } ing with the face up-
SUPINENESS, *n. s.* } ward : opposed to
SUPINEITY. } prone : leaning back-
 ward ; exposed ; negligent ; careless : the ad-
 verb and noun-substantive corresponding.

Who on the beds of sin *supinely* lie,
 They in the summer of their age shall die. *Sandys.*
 These men suffer by their absence, silence, negli-
 gence, or *supine* credulity. *King Charles.*

The fourth cause of error is a *supinity* or neglect of enquiry, even in matters wherein we doubt, rather believing than going to see.

Browne's Vulgar Errors.

Upon these divers positions in man, wherein the spine can only be at right lines with the thigh, arise those remarkable postures, prone, *supine*, and erect. *Id.*

The old imprisoned king,
 Whose lenity first pleased the gaping crowd ;
 But when long tried, and found *supinely* good,
 Like Æsop's log, they leapt upon his back. *Dryden.*

At him he lanced his spear, and pierced his breast ;
 On the hard earth the Lycian knocked his head,
 And lay *supine* ; and forth the spirit fled. *Id.*

If the vine
 On rising ground be placed, or hills *supine*,
 Extend thy loose battalions. *Id.*

What advantage hath a man by this erection above other animals, the faces of most of them being more *supine* than ours ? *Ray on the Creation.*

Wilt thou then repine
 To labour for thyself ? and rather chuse
 To lie *supinely*, hoping heaven will bless
 Thy slighted fruits, and give thee bread unearned ?
Philips.

Supine in Sylvia's snowy arms he lies,
 And all the busy cares of life defies. *Tatler.*

Beneath a verdant laurel's shade,
 Horace, immortal bard ! *supinely* laid. *Prior.*

When this door is open to let dissenters in, considering their industry and our *supineness*, they may in a very few years grow to a majority in the house of commons. *Swift.*

SUPINE, in the Latin grammar, part of the conjugation of a verb, being a verbal substantive of the singular number and the fourth declension. There are two kinds of *supines* ; one called the first *supine*, ending in *um* of the accusative case, which is always of an active signification, and follows a verb of motion ; *abiit deambulatum*. The other, called the last *supine*, and ending in *u* of the ablative case, is of a passive signification, and is governed by substantives or adjectives ; as *facile dictu*, &c. They have their name, says Probus, and after him Vossius, quod ad instar *supinorum* et *otiosorum hominum omnia habent confusa* ; or, according to Priscian, quod nascuntur a participiis passivis, quæ *supina* appellata sunt, quia, in infimo loco sita, totam conjugationis molem suscipiant.

SUPPEDANEOUS, *adj.* Lat. *sub* and *pes*. Placed under the feet.

He had slender legs, but increased by riding *afes* meals ; that is, the humour descended upon their pendulosity, they having no support or *suppedaneous* stability. *Browne.*

SUPPER, *n. s.* } Fr. *souper*. From *sup*.
SUPPERLESS, *adj.* } The last meal of the day ;
 the evening repast : wanting supper.

To-night we hold a solemn *supper*. *Shakspeare.*

I'll to my book :

For yet, ere *supper*-time must I perform
much business.

Id. Tempest.

The' hour of *supper* comes unearned. *Milton.*

His physicians, after his great fever that he had
in Oxford, required him to eat *suppers*.

Fell.

Suppose a man's going *supperless* to bed should
introduce him to the table of some great prince.

Spectator.

She eyed the bard, where *supperless* he sat,
And pined, unconscious of his rising fate. *Pope.*

A SUPPER of heavy food should be avoided, because the stomach is more oppressed with the same quantity of food in an horizontal posture than in an erect one, and because digestion goes on more slowly when we sleep than when we are awake. It should be eaten long enough before bed-time, that it may be nearly digested before going to sleep ; and then a draught of pure water will dilute that which remains in the stomach.

SUPPER OF THE LORD, otherwise called the Eucharist, is a sacrament ordained by Christ in his church, of which the outward part is bread and wine, and the inward part or thing signified the body and blood of Christ, which the majority of Christians believe to be in some sense or other taken and received by the faithful communicants. See SACRAMENT. There is no ordinance of the gospel which has been the subject of more violent controversies between different churches, and even between different divines of the same church, than this sacrament ; and, though all confess that one purpose of its institution was to be a bond of love and union among Christians, it has, by the perverseness of mankind, been too often converted into an occasion of hatred. The outward and visible sign, and the inward and spiritual grace, have equally afforded matter of disputation to angry controversialists. Many members of the church of Rome condemn the Greek church and the Protestants for using leavened bread in the Lord's Supper, contrary to the example set them by our Saviour ; whilst the Greek church in general, and some Protestant societies in particular, unite with the church of Rome in censuring all churches which mix not the wine with water, as deviating improperly from primitive practice. See EUCHARIST. That it was unleavened bread which our Lord blessed and brake and gave to his disciples as his body, cannot be questioned : for at the time of the passover, when this ordinance was instituted, there was no leavened bread to be found in Jerusalem. For the mixed cup the evidence is not so decisive. It is indeed true that the primitive Christians used wine diluted with water ; and Maimonides says it was the general custom of the Jews, as well at the passover as at their ordinary meals, to add a little water to their wine on account of its great strength ; but that this was always done, or that it was done by our Saviour in particular, there is no clear evidence. Origen indeed affirms that our Lord administered in wine unmixed ; and he was not a man to hazard such an affirmation, had there been in his days any certain tradition, or so much as a general opinion to the contrary. On this account

we have often heard with wonder the necessity of the mixed cup insisted on by those who without hesitation make use of leavened bread ; for, if it be essential to the sacrament that the very same elements be employed by us that were employed by our Saviour, the necessity of unleavened bread is certainly equal to that of wine diluted by water. But the mixed cup is said to be emblematical of the blood and water which flowed from the side of our Lord when pierced by the spear of the Roman soldier, while the absence of leaven is emblematical of no particular circumstance in his passion. This argument for the mixture is as old as the era of St. Cyprian, and has since been frequently urged with triumph by those who surely perceived not its weakness. The flowing of the blood and water from our Saviour's side was probably the consequence of the spear's having pierced the pericardium. But, whatever was the cause of it, how can the mixing of wine with water in the sacrament be emblematical of the flowing of blood and water separately ? We urge not these objections to the mixed cup from any dislike to the practice. It is unquestionably harmless and primitive ; and we wish that greater regard were paid to primitive practices than most of Christians seem to think they can claim ; but let the advocates for antiquity be consistent ; let them either restore, together with the mixed cup, the use of unleavened bread, or acknowledge that neither the one nor the other is essential to the sacrament. This last acknowledgment must indeed be made if they would not involve themselves in difficulties from which they cannot be extricated. If either the mixed cup of unleavened bread be absolutely necessary to the validity of the sacrament, why not wine made from the grapes of Judea ? But the controversies respecting the outward part of the sign of the Lord's Supper are of little importance when compared with those which have been agitated respecting the inward part or thing signified ; and of these we hasten to give as comprehensive a view as the limits prescribed to such articles will admit.

The institution of the Lord's Supper, as recorded in the gospel by St. Matthew, St. Paul, St. Mark, and St. Luke, we need not quote. That it was the bread which Christ blessed and brake that is called his body, and the wine over which he gave thanks that he styles his blood of the new testament, will admit of no reasonable doubt ; but in what sense they became so has been the subject of many controversies. The church of Rome, which holds that, after consecration, Jesus Christ, God and man, is really, truly, and substantially contained under the outward appearance of the bread and wine, informs us that, about the middle of the mass, when the priest, taking into his hand, first the bread, and then the wine, pronounces over each separately the sacred words of consecration, the substance of these elements is immediately changed by the almighty power of God into the body and blood of Christ ; but that all the outward appearances of the bread and wine, and all their sensible qualities remain. This more than miraculous change is called transubstantiation ; and has been traced to the philosophy of Aris-

tole, which resolves all bodies into matter and form (see PHILOSOPHY); for it is only the matter or imperceptible substance which supports the forms or sensible quantities of bread and wine, and is changed into the substance or matter of the body and blood of Christ, so that this divine matter, coming into the place of the former earthy matter, supports the same identical forms which it supported. Hence we are told 'that Jesus Christ, now present instead of the bread and wine, exhibits himself to us under those very same outward forms or appearances which the bread and wine had before the change.' See TRANSUBSTANTIATION. The churches of England and Scotland, in their established doctrine respecting the Lord's Supper, appear to be Calvinistical; but the compilers of the Thirty-nine Articles and of the Confession of Faith must have been much more rational divines than Beza and Peter Martyr. They agree in condemning the doctrine of transubstantiation as contrary to common sense, and not founded on the word of God; they teach that to such as rightly, worthily, and with faith, receive the sacrament, the bread which we break is a partaking of the body of Christ, and the cup of blessing a partaking of the blood of Christ; and they add that the body and blood of Christ are eaten and drunk, not corporally and carnally, but only after a heavenly and spiritual manner, by which the communicants are made partakers of all the benefits of his death. In one important circumstance these two churches seem to differ. The Confession of Faith affirms that, in the Lord's Supper, there is no sacrifice made at all. The thirty-first article of the church of England likewise condemns the popish sacrifice of the mass as a blasphemous fable and dangerous deceit; but in the order for the administration of the Lord's Supper, or Holy Communion, the celebrator 'beseeches God most mercifully to accept the alms and oblations of the congregation,' and again, 'to accept their sacrifice of praise and thanksgiving:' from which petitions many have inferred that, in the Lord's Supper, that church offers a commemorative and eucharistical sacrifice. This inference seems not to be wholly without foundation. In the order for the administration of the Lord's Supper, according to the form of the book of Common Prayer set forth by act of parliament in the second and third years of king Edward VI., the elements were solemnly offered to God as a sacrifice of praise and thanksgiving; but the prayer containing that oblation was, at the review of the liturgy some years afterwards, removed from the prayer of consecration, to which it was originally joined, and placed where it now stands in the post-communion service. The English church, however, has not positively determined any thing respecting this great question: and whilst she condemns the doctrine of the real presence, with all its dangerous consequences, she allows her members to entertain very different notions of this holy ordinance, and to publish these notions to the world. Accordingly, many of their most eminent divines, particularly archbishops Laud and Wake; the bishops Poynt, Andrews, Bull, and Patrick; the doctors Hickes, Crabe, and Brett; Messrs.

Bingham, Johnson, Mede, Wheatly, Scandaret, Bowyer, &c., have maintained that, in the celebration of the Lord's Supper, the elements of bread and wine are offered to God as a sacrifice commemorative of Christ's one sacrifice for the sins of the whole world: that these elements, though they undergo no substantial change, yet receive such a divine virtue, by the descent of the Holy Ghost, as to convey to the worthy communicant all the benefits of Christ's passion: that they are therefore called his body and blood; because being, after their oblation, eaten and drunk in remembrance of him, they supply the place of his body and blood in the feast upon his sacrifice; and that it is customary with our Saviour to give to any thing the name of another of which it completely supplies the place, as when he calls himself the door of the sheep, because there is no entrance into the church or kingdom of God but by faith in him. They observe that the Eucharist's being commemorative, no more hinders it from being a proper sacrifice than the typical and figurative sacrifices of the old law hindered them from being proper sacrifices: for as to be a type doth not destroy the nature and notion of a legal sacrifice, so to be representative and commemorative doth not destroy the nature of an evangelical sacrifice.

Our limits will not permit us to give even an abstract of their arguments; but the reader who wishes to see more of the subject may peruse Johnson's unbloody Sacrifice and Altar unveiled and supported; whence he may discover that their notions are totally irreconcilable with the doctrine of transubstantiation and the popish sacrifice of the mass. Other English divines of great learning, with the celebrated Hoadley bishop of Winchester, contend strenuously that the Lord's Supper, so far from being a sacrifice of any kind, is nothing more than bread and wine reverently eaten and drunk, in remembrance that Christ's body was broken and his blood shed in proof of his Father's and his own love to mankind; that nothing is essential to the sacrament but this remembrance, and a serious desire to honor and obey our Saviour as our head; that the sacrament might be celebrated without uttering one prayer or thanksgiving, merely by a society of Christians, whether small or great, jointly eating bread and drinking wine with a serious remembrance of Christ's death; that St. Paul enjoins a man to examine himself before he eat of that bread and drink of that cup, not to discover what have been the sins of his past life in order to repent of them, but only that he may be sure of remembering Christ's body broken and his blood shed; that, however, it is his duty in that as in every other instance of religious worship, to resolve to obey from the heart every precept of the gospel, whether moral or positive; and that to partake worthily of the Lord's Supper is acceptable to God, because it is paying obedience to one of these precepts; but that no particular benefits or privileges are annexed to it more than to any other instance of duty. The celebrated archbishop Tillotson advances the same doctrine in his *Persuasive to Frequent Communion*. Bishop Hoadley acknowledges that when St. Paul says, 'The cup

of blessing which we bless, is it not the communion of the blood of Christ? The bread which we break, is it not the communion of the body of Christ? he has been supposed by many learned men to affirm that all the benefits of Christ's passion are in the Lord's Supper conveyed to the worthy communicant; but this, says he, is an idea which the apostle could not have in his thoughts as at all proper for his argument. The Greek word *κοινωνια*, and the English communion, signify only a partaking of something in common with others of the same society; and the apostle's meaning, he says, can be nothing more than that in the Lord's Supper we do not eat bread and drink wine as at an ordinary meal, but as memorials of the body and blood of Christ, in honor to him as the head of that body of which we are all members. That the word *κοινωνια* is not meant to denote any inward or spiritual part of the Lord's Supper he thinks evident, because the same word is used with regard to the cup and the table of idols, where no spiritual part could be thought of, and in an argument which supposes an idol to be nothing. Other divines steer a middle course between the mere memorialist and the advocate for a real sacrifice in the holy Eucharist, and insist that this rite, though no sacrifice itself, is yet a feast upon the one sacrifice offered by Christ, and slain upon the cross. The most eminent patrons of this opinion have been Dr. Cudworth, bishop Warburton, and Dr. Cleaver, bishop of St. Asaph; and they support it by such arguments as the following:—'In those ages of the world when victims made so great a part of the religion both of Jews and Gentiles, the sacrifice was always followed by a religious feasting on the thing offered; which was called the feast upon or after the sacrifice, and was supposed to convey to the partakers of it the benefits of the sacrifice. Now Jesus, say they, about to offer himself a sacrifice on the cross for our redemption, did, in conformity to general practice, institute the last supper, under the idea of a feast after the sacrifice; and the circumstances attending its institution were such, they think, that the apostles could not possibly mistake his meaning. It was just before his passion, and while he was eating the paschal supper, which was a Jewish feast upon the sacrifice, that our blessed Lord instituted this rite; and as it was his general custom to allude, in his actions and expressions, to what passed before his eyes, or presented itself to his observation, who can doubt when, in the very form of celebration, we see all the marks of a sacrificial supper, but that the divine institutor intended it should bear the relation to his sacrifice on the cross which the paschal supper then celebrating bore to the oblation of the paschal lamb?' Thus have we given such a view as our limits permit of the principal opinions that have been held respecting the nature and end of the Lord's Supper. After all a plain Christian, who is not willing to believe more than what is in Scripture, nor is fettered with the prejudices of particular sects or parties, will be apt to think that both Protestants and Roman Catholics have darkened counsel by words without knowledge, upon a very plain, simple, com-

memorative ceremony. The late Mr. Barclay, the Berean, often said, 'the Papists had made a god of it, and most Protestants had made it a demi-god.'

SUPPLANT', *v. a.* Fr. *supplanter*; Lat. *sub* and *planta*. To trip up the heels; displace by stratagem; overpower.

It is Philoclea his heart is set upon; it is my daughter I have borne to *supplant* me. *Sidney.*

If it be fond, call it a woman's fear;
Which fear, if better reasons can *supplant*,
I will subscribe, and say, I wronged the duke. *Shakspeare.*

Upon a just survey, take Titus' part,
And so *supplant* us for ingratitude. *Id.*

For such doctrines as depend merely upon institution and the instruction of others, men do frequently differ both from themselves and from one another about them; because that which can plant, can *supplant*. *Wilkins.*

His legs entwining
Each other, till *supplanted* down he fell
A monstrous serpent on his belly prone. *Milton.*

Suspecting that the courtier had *supplanted* the friend. *Fell.*

The thronging populace with hasty strides
Obstruct the easy way; the rocking town
Supplants their footsteps; to and fro they reel. *Philips.*

SUP'PLE, *adj. v. a. &* } Fr. *souple*. Pliant;
 SUP'PLENESS, *n. s.* { *v. n.* } flexible; yielding: hence fawning; flattering: to make pliant or soft: to grow soft or pliant: the noun substantive corresponding.

When we've stuffed
These pipes and these conveyances of blood
With wine and feeding, we have *suppler* souls
Than in our priestlike fasts. *Shakspeare.*

Each part deprived of supple government,
Shall stiff, and stark, and cold appear, like death. *Id.*

Knaves having, by their own importunate suit,
Convinced or *suppled* them, they cannot chuse,
But they must blab. *Id. Othello.*

The joints are more *supple* to all feats of activity
in youth than afterwards. *Bacon.*

Will ye submit your necks, and chuse to bend
The *supple* knee? *Milton.*

Study gives strength to the mind, conversation
grace; the first apt to give stiffness, the other *suppleness*. *Temple.*

No women are apter to spin linen well than the Irish, who, labouring little in any kind with their hands, have their fingers more *supple* and soft than other women of the poorer condition in England. *Id.*

Ev'n softer than thy own. of *suppler* kind,
More exquisite of taste, and more than man refined. *Dryden.*

The stones
Did first the rigour of their kind expel,
And *suppled* into softness as they fell. *Id.*

A mother persisting till she had bent her daughter's mind, and *suppled* her will, the only end of correction, she established her authority thoroughly ever after. *Locke on Education.*

If punishment reaches not the mind, and makes not the will *supple*, it hardens the offender. *Locke.*

There is something so *supple* and insinuating in this absurd unnatural doctrine, as makes it extremely agreeable to a prince's ear. *Addison.*

To *supple* a carcase, drench it in water. *Arbutnot.*

SUPPLEMENT, *n. s.* } Fr. *supplement* ;
 SUPPLEMENTAL, *adj.* } Latin *supplementum*.
 SUPPLEMENTARY. } Addition to any thing
 by which its defects are supplied ; supply ; store :
 the adjectives corresponding.

Unto the word of God, being in respect of that end for which God ordained it, perfect, exact, and absolute in itself, we do not add reason as a *supplement* of any maim or defect therein, but as a necessary instrument, without which we could not reap by the Scripture's perfection that fruit and benefit which it yieldeth. *Hooker.*

We had not spent
 Our ruddie wine a-ship-board : *supplement*
 Of large sort each man to his vessel drew. *Chapman.*
 Divinity would not then pass the yard and loom,
 nor preaching be taken in as an easier *supplementary*
 trade, by those that disliked the pains of his own.
Decay of Piety.

Supplemental acts of state were made to supply defects of laws ; and so tonnage and pounce were collected. *Clarendon.*

Provide his brood next Smithfield fair,
 With *supplemental* hobby horses ;
 And happy be their infant courses. *Prior.*

His blood will atone for our imperfection, his righteousness be imputed in *supplement* to what is lacking in ours. *Rogers.*

Instructive satire, true to virtue's cause !
 Thou shining *supplement* of public laws ! *Young.*

SUPPLEMENT, in literature, an appendage to supply what is wanting in a book. It has been generally remarked, that no literary work stands so much in need of a supplement as a dictionary of arts and sciences, on account of the successive and daily progress and improvement of the arts and sciences.

SUPPLEMENT OF AN ARCH OR ANGLE, in geometry or trigonometry, is what it wants of a semicircle, or of 180° ; as the complement is what it wants of a quadrant, or of 90°. So the supplement of 50° is 130° ; as the complement of it is 40°.

SUPPLETORY, *n. s.* Lat. *suppletorium*. That which is to fill up deficiencies.

That *suppletory* of an implicit belief is by Romanists conceived sufficient for those not capable of an explicit. *Hammond.*

SUPPLIANT, *adj.* & *n. s.* Fr. *suppliant*. Entreating ; beseeching ; submissive : he who begs in that manner.

To those legions your levy
 Must be *suppliant*. *Shakespeare. Cymbeline.*
 A petition from a Florentine I undertook,
 Vanquished thereto by the fair grace and speech
 Of the poor *suppliant*. *Shakespeare.*

To bow and sue for grace with *suppliant* knee.
Milton.
 The rich grow *suppliant*, and the poor grow proud :
 Those offer mighty gain, and these ask more. *Dryden.*

Hourly suitors come :
 The east with incense, and the west with gold,
 Will stand like *suppliants* to receive her doom. *Id.*
 Constant to his first decree,
 To bow the haughty neck, and raise the *suppliant*
 knee. *Prior.*

SUPPLICATE, *v. n.* } Fr. *supplier* ; Lat.
 SUPPLICATION, *n. s.* } *supplicatio*, from *supplex*.
 To implore ; entreat ; petition submissively : the
 noun substantive corresponding.

Praying with all prayer and *supplication*, with all perseverance and *supplication* for all saints.

Ephesians vi. 18.
 The prince and people of Nineveh assembling themselves a main army of *suppliants*, God did not withstand them. *Hooker.*

My lord protector will come this way by and by, and then we may deliver our *supplications* in the quill. *Shakespeare.*

My mother bows,
 As if Olympus to a mole-hill should
 In *supplication* nod. *Id. Coriolanus.*
 Many things a man cannot with any comeliness say
 or do ; a man cannot brook to *supplicate* or beg.
Bacon.

Bend thine ear
 To *supplication* ; hear his sighs though mute.
Milton.

We should testify our dependence upon God, and our confidence of his goodness, by constant prayers and *supplications* for mercy. *Tillotson.*

These prove the common practice of the worship of images in the Roman church, as to the rites of *supplication* and adoration, to be as extravagant as among the heathens. *Stillingfleet.*

Thither the kingdoms and the nations come,
 In *supplicating* crowds, to learn their doom. *Addison.*

A second sort of publick prayer is, that all in a family that are members of it join in their common *supplications*. *Duty of Man.*

The wise *suppliant*, though he prayed for the condition he thought most desirable, yet left the event to God. *Rogers.*

Abraham, instead of indulging the *suppliant* in his desire of new evidence, refers him to what his brethren had. *Atterbury.*

SUPPLICATIO, in antiquity, a religious solemnity observed on account of any remarkable success against an enemy ; and especially when the army had conferred the title of imperator on their general. On such occasions the imperator sent messengers, crowned with laurel, with letters to the senate, which were likewise adorned with laurel, to demand of them the title of imperator, and the honor of a supplication. The solemnity consisted in sacrificing and feasting in the temples, with giving thanks to the gods for success obtained, and praying for the continuance of their assistance. At first there were only a few days taken up in such festivals ; but afterwards they were increased gradually, till they came to no less than fifty. On subduing the Sabines, in the year of the city 304, a supplication of one day only was ordained ; on the taking of Veii, Camillus had a supplication of four days decreed him ; Pompey had twelve on putting an end to the Mithridatic war ; Cæsar had fifteen, and afterwards twenty, for reducing Gaul ; Octavianus and Pansa had fifty days of supplication for delivering the colony of Mutina.

SUPPLICAVIT, a writ issuing out of chancery, for taking surety of the peace, when one is in danger of being hurt in his body by another ; it is directed to the justices of the peace and sheriff of the county, and is grounded upon the stat. 1 Edw. III., stat. 2, c. 16, which ordains that certain persons shall be assigned by the chancellor to take care of the peace, &c.—F. N. B. 80, 81. When a man hath purchased a writ of supplicavit, directed to the justices of the peace,

against any person, then he, against whom the writ is sued, may come into the chancery, and there find sureties that he will not do hurt or damage unto him that sueth the writ; and upon that he shall have a writ of supersedeas, directed to the justices, &c., reciting his having found sureties in chancery, according to the writ of supplicavit: and also reciting that writ, and the manner of the security that he hath found, &c., commanding the justices that they cease to arrest him, or to compel him to find sureties, &c. And, if the party who ought to find sureties cannot come into the chancery to find sureties, his friend may sue a supersedeas in chancery for him; reciting the writ of supplicavit, and that such a one and such a one are bound for him in the chancery in such a sum, that he shall keep the peace according to it; and the writ shall be directed to the justices, that they take surety of the party himself, according to the supplicavit, to keep the peace, &c., and that they do not arrest him; or, if they have arrested him for that cause, that they deliver him.—New Nat. Br. 180. Sometimes the writ of supplicavit is made returnable into the chancery at a certain day; and, if so, and the justices do not certify the writ, nor the recognizance, and the security taken, the party who sued the supplicavit shall have a writ of certiorari directed unto the justices of peace to certify the writ of supplicavit, and what they have done thereupon, and the security found, &c.—New Nat. Br. 180. If a recognizance of the peace be taken in pursuance of a writ of supplicavit, it must be wholly governed by the directions of such writ; but, if it be taken before a justice of peace below, the recognizance may be at the discretion of such justice.—Lamb. 100; Daï: c. 70.

At the common law it was sufficient, in order to obtain this process for surety of the peace from the court of chancery, if the party who demanded it made oath that he was in fear of some corporal hurt, and that he did not crave the same out of malice, but for the safety of his body.—F. N. B. 79, 80. But by stat. 21 Jac. I., c. 8, all process of the peace shall be void, unless granted on motion in open court on affidavit in writing.

When articles of the peace are exhibited in the court of chancery, and oath is made that the surety of the peace is not craved by the party through malice, but for the safety of his life, a writ of supplicavit issues, directed to the justices of the peace generally, or to some one justice of the peace, or to the sheriff, commanding them or him to take security in the sum thereon indorsed; and, if the surety refuses to find such security, to commit him to the town gaol until he does find such security. If there be no proceedings on a supplicavit within a year, the recognizance is of course discharged; and, if the party be committed after the expiration of that time, he shall be discharged upon very slight security.—Fitz. 268. If taken below, and the party appear pursuant to the condition, no indictment being lodged, he must be discharged.—Hardwick's Cases. But the court in discretion may refuse to discharge a recognizance, even though the exhibitant appear and consent; for a breach against any other person is equally a forfeiture.

SUPPLY, *v. a. & n. s.* Fr. *suppléer*; Lat. *suppleo*. To fill up as deficiencies happen; afford what is wanted; yield; serve instead of; accommodate; give or bring: the noun substantive means relief of want; cure of want or deficiency.

I mean that now your abundance may be a *supply* for their want, that their abundance also may be a *supply* for your want. 2 Cor. viii. 14.

Out of the fry of these rakehell horseboys are their kearn *supplied* and maintained. Spenser.

Although I neither lend nor borrow,
Yet, to *supply* the ripe wants of my friend,
I'll break a custom.

Shakspeare. Merchant of Venice.

They were princes that had wives, sons, and nephews; and yet all these could not *supply* the comfort of friendship. Bacon.

The reception of light must be *supplied* by some open form of the fabrick. Wotton.

Upstart creatures to *supply* our vacant room. Milton

Burning ships the banished sun *supply*,
And no light shines but that by which men die. Waller.

I wanted nothing fortune could *supply*,
Nor did she slumber till that hour deny. Dryden.

While trees the mountain-tops with shades *supply*,
Your honour, name, and praise, shall never die. Id.

Nearer care *supplies*

Sighs to my breast, and sorrow to my eyes. Prior.

Art from that fund each just *supply* provides,
Works without show, and without pomp presides. Pope.

My lover, turning away several old servants, *supplied* me with others from his own house. Swift.

SUPPORT, *v. a. & n. s.* Fr. *supporter*; Ital. **SUPPORTABLE**, *adj.* } *supportare*. To sustain; prop; bear up;
SUPPORTANCE, *n. s.* } endure: all the noun
SUPPORTATION, } substantives, and the
SUPPORTER. } adjective following, correspond: the last two noun substantives are obsolete.

As great to me, as late; and, *supportable*,
To make the dear loss, have I means much weaker
Than you may call to comfort you.

Shakspeare. Tempest.

You must walk by us upon either hand,
And good *supporters* are you.

Id. Measure for Measure.

Give some *supportance* to the bending twigs.

Shakspeare.

The benefited subject should render some small portion of his gain for the *supportation* of the king's expence. Bacon.

The sockets and *supporters* of flowers are figured. Id.
More might be added of helms, crests, mantles, and *supporters*. Camden.

The beginning of the earl of Essex I must attribute in great part to my lord of Leicester; but yet as an introducer or *supporter*, not as a teacher. Wotton.

Such propositions as these are competent to blast and defame any cause which requires such aids, and stands in need of such *supporters*. Hammond.

Stooping to *support* each flower of tender stalk. Milton.

Strongly to suffer and *support* our pains. Id.

With inward consolations recompensed,

And oft *supported*.

Id.

We shall be discharged of our load; but you, that are designed for beams and *supporters*, shall bear.

L'Estrange.

This fierce demeanour, and his insolence,
The patience of a god could not *support*. *Dryden*.

She scarce awake her eyes could keep,
Unable to *support* the fumes of sleep. *Id.*

Love was no mote, when loyalty was gone,
The great *supporters* of his awful throne. *Id.*

Though the idea we have of a horse or stone be but the collection of those several sensible qualities which we find united in them; yet, because we cannot conceive how they should subsist alone, we suppose them existing in and supported by some common subject, which *support* we denote by the name substance, though it be certain we have no clear idea of that *support*. *Locke*.

Because a relation cannot be founded in nothing, and the thing here related as a *supporter*, or a *support*, is not represented to the mind by any distinct idea. *Id.*

There is no loss of room at the bottom, as there is in a building set upon *supporters*. *Mortimer*.

The saints have a companion and *supporter* in all their miseries. *South*.

None can *support* a diet of flesh and water without acids, as salt, vinegar, and bread, without falling into a putrid fever. *Arbuthnot*.

I wish that whatever part of misfortunes they must bear, may be rendered *supportable* to them. *Pope*.

Alterations in the project of uniting Christians might be very *supportable*, as things in their own nature indifferent. *Swift*.

SUPPORTED, in heraldry, a term applied to the uppermost quarters of a shield when divided into several quarters, these seeming as it were supported or sustained by those below. The chief is said to be supported when it is of two colors, and the upper color takes up two-thirds of it. In this case it is supported by the color underneath.

SUPPOSE, *v. a. & n. s.*
SUPPOSABLE, *adj.*
SUPPOSAL, *n. s.*
SUPPOSER,
SUPPOSITION,
SUPPOSITIOUS, *adj.*
SUPPOSITIOUS,
SUPPOSITIVELY, *adv.*

Fr. supposer; *Lat. suppono*. To lay down without proof; advance or suggest without maintaining the truth of the position; to assume;

admit without proof; imagine; make to appear reasonable as a consequence: suppose, noun substantive, has been barbarously used for supposition: supposable signifies, that may be supposed or conjectured: supposal is but a synonyme of supposition: supposer, he who supposes: supposition, position or hypothesis assumed; unproved imagination: suppositious, imaginary; unreal; spurious: suppositively, upon supposition.

Let not my lord *suppose* that they have slain all the king's sons; for Amnon only is slain. *2 Sam. xiii. 32.*

Tell false Edward, thy *supposed* king,
That Lewis of France is sending over maskers. *Shakspeare*.

Young Fortinbras,
Holding a weak *supposal* of our worth,
Thinks our state to be out of frame. *Id.*

We come short of our *suppose* so far,
That, after seven years siege, yet Troy-walls stand. *Id.*

Thou hast by marriage made thy daughter mine,
While counterfeit *supposers* bleered thine eyne. *Id.*
In saying he is a good man, understand me that he is sufficient; yet his means are in *supposition*. *Id.*
The destruction of Mustapha was so fatal to Soly-

man's line as the succession of the Turks from Solyman is suspected to be of strange blood, for that Selymus II. was thought to be *supposititious*. *Bacon*.

Invincible ignorance is, in the far greatest number of men, ready to be confronted against the necessity of their believing all the severals of any *supposable* catalogue. *Hammond*.

When this comes, our former *supposal* of sufficient grace, as of the preaching of the word, and God's calls, are utterly at an end. *Id.*

The unreformed sinner may have some hope *suppositively*, if he do change and repent: the honest penitent may hope positively. *Id.*

Where we meet with all the indications and evidences of such a thing, as the thing is capable of, *supposing* it to be true, it must needs be very irrational to make any doubt of it. *Wilkins*.

I *suppose* we should compel them to a quick result. *Milton*.

This *supposeth* something, without evident ground. *Hale*.

Little can be looked for towards the advancement of natural theory, but from those that are likely to mend our prospect: the defect of events, and sensible appearances, suffer us to proceed no further towards science, than to imperfect guesses and timorous *supposals*. *Glanville's Scepis, Preface*.

This is to be entertained as a firm principle, that when we have as great assurance that a thing is, as we could possibly, *supposing* it were, we ought not to make any doubt of its existence. *Tillotson*.

This is only an infallibility upon *supposition*, that if a thing be true, it is impossible to be false. *Id.*

There is a Latin treatise among the *supposititious* pieces ascribed to Athanasius. *Waterland*.

Is Egypt's safety, and the king's, and your's,
Fit to be trusted on a bare *suppose*
That he is honest? *Dryden's Cleomenes*.

Suppose some so negligent that they will not be brought to learn by gentle ways, yet it does not thence follow that the rough discipline of the cudgel is to be used to all. *Locke*.

Interest, with a Jew, never proceeds but upon *supposal* at least of a firm and sufficient bottom. *South*.

It is their opinion, that no man ever killed his father; but that, if it should ever happen, the reputed son must have been illegitimate, *supposititious*, or begotten in adultery. *Addison*.

Some alterations in the globe tend rather to the benefit of the earth, and its productions, than their destruction, as all these *supposititious* ones manifestly would do. *Woodward*.

Such an original irresistible notion is neither requisite upon *supposition* of a Deity, nor is pretended to by religion. *Bentley*.

One falsehood always *supposes* another, and renders all you can say suspected. *Female Quixotte*.

Artful men endeavour to entangle thoughtless women by bold *supposals* and offers. *Clarissa*.

SUPPOSITION, in music, is when one of the parts dwells on a note, while another part makes two or three more lesser notes equivalent to it, by conjoint degrees. Supposition is defined the using of two successive notes of the same value as to time; the one whereof, being a discord, supposes the other a concord. The harmony, Mr. Malcolm observes, is always to be full on the accented parts of the bar or measure; but on the unaccented, discords may transiently pass, without any offence to the ear. This transient use of discords, followed by con-

cords, make what we, after the French, call supposition. Concorde by supposition are those where the continued bass adds or supposes a new sound below the fundamental bass; whence such concords always exceed the extent of the octave. Of these concords there are three sorts, all which are concords of the seventh; the first, when the added sound is a third below the fundamental sound; such is the concord of the ninth; and if the concord of the ninth is formed by the mediant, added below the sensible concord in the minor mode, then the concord is called the superfluous fifth. The second kind is, when the supposed sound is a fifth below the fundamental sound, as in the concord of the fourth or eleventh; and if the concord is sensible, and the tonic be supposed, this concord is called the superfluous seventh. The third kind is that where the supposed sound is below a concord of the diminished seventh; if it is a fifth below, i. e. if the supposed sound be the mediant, the concord is called the concord of the fourth and superfluous fifth: if it is a seventh below, i. e. if the supposed sound be the tonic, the concord is called the lesser sixth and superfluous seventh.

SUPPOSITORY, *n. s.* Fr. *suppositoire*; Lat. *suppositorium*. A kind of solid clyster.

Nothing relieves the head more than the piles; therefore *suppositories* of honey, aloes, and rocksalt ought to be tried. *Arbuthnot.*

A **SUPPOSITORY** is a kind of medicated cone, which is introduced into the anus for opening the belly. It is usually composed of common honey, mixed up with either soap or oil, and formed into pieces of the length and thickness of the little finger, only pyramidal. To the composition is sometimes also added powder of scammony, euphorbium, colocynthis, salt, aloes, &c, according to the case of the patient. The suppository was invented for the convenience of such as have an aversion to the taking of clysters; or to be used when the disease does not allow thereof.

SUPPRESS, *v. a.* } Fr. *supprimer*; Latin
SUPPRESSION, *n. s.* } *supprimo, suppressus*. To
SUPPRESSOR. } crush; overpower; overwhelm; subdue; reduce to inactivity; to hide; conceal; keep in: the noun substantives corresponding.

Glo'ster would have armour out of the Tower,
 To crown himself king, and suppress the prince.

Shakspeare. Henry VI.

Well did'st thou, Richard, to suppress thy voice;
 For, had the passions of thy heart burst out,
 I fear we should have seen decyphered there
 More ranc'rous spite, more furious raging broils.

Shakspeare.

Every rebellion, when it is suppressed, doth make the subject weaker, and the prince stronger.

Davies on Ireland.

Sir William Herbert, with a well armed and ordered company, set sharply upon them; and, oppressing some of the forwardest of them by death, suppressed the residue by fear.

Hayward.

Things not revealed, which the invisible King,
 Only omniscient, hath suppressed in night.

Milton.

You may depend upon a suppression of these verses.

Pope.

Still she suppresses the name, and this keeps him

in a pleasing suspense; and, in the very close of her speech, she indirectly mentions it.

Brooma on the Odyssey.

SUPPRESSION, in medicine, is generally used to signify a retention of urine or of the menses.

SUPPURATION is the second way wherein an inflammation terminates; being a conversion of the inspissated blood and the first adjacent parts, as the vessels and fat into pus or matter; which disorder, when it has not yet found an opening, is generally called an abscess.

SUPPURATE, *v. a.* Fr. *suppurer*; Latin *pus puris*. To generate pus or matter.

The great physician of souls sometimes cannot cure without cutting us: sin has festered inwardly, and he must lance the imposthume, to let out death with the *suppuration*.

South.

If the inflammation be gone too far towards a *suppuration*, then it must be promoted with *suppuratives*, and opened by incision.

Wiseman.

This great attrition must produce a great propensity to the putrescent alkaline condition of the fluids, and consequently to *suppurations*.

Arbuthnot on Aliments.

This disease is generally fatal: if it *suppurates* the pus, it is evacuated into the lower belly, where it produceth putrefaction.

Id. On Diet.

SUPPUTATION, *n. s.* Fr. *supputation*; Lat. *supputo*. Reckoning; account; calculation. Not used.

From these differing properties of day and year, arise difficulties in carrying on and reconciling the *supputation* of time in long measures.

Holder on Time.

The Jews saw every day their Messiah still farther removed from them; that the promises of their doctors, about his speedy manifestations, were false; that the predictions of the prophets whom they could now no longer understand, were covered with obscurity; that all the *supputations* of time either terminated in Jesus Christ, or were without a period.

West.

SUPRALAPSARIAN, *adj.* } Lat. *supra* and
SUPRALAPSARY. } *lapsus*. Antecedent to the fall of man.

The *supralapsarians*, with whom the object of the decree is homo conditus, man created, not yet fallen; and the *sublapsarians*, with whom it is man fallen, or the corrupt mass.

Hammond.

SUPRALAPSARIANS, in theology, are persons who hold that God, without any regard to the good or evil works of men, has resolved, by an eternal decree, *supra lapsum*, antecedently to any knowledge of the fall of Adam, and independently of it, to save some and to damn others; or, in other words, that God intended to glorify his justice in the condemnation of some, as well as his mercy in the salvation of others; and for that purpose decreed that Adam should necessarily fall, and by that fall bring himself and all his offspring into a state of everlasting condemnation. These are also called *antelapsarians*, and are opposed to *sublapsarians* and *infralapsarians*. According to the *supralapsarians*, the object of predestination is, homo creabilis et labilis; and, according to the *sublapsarians*, and *infralapsarians*, homo creatus et lapsus.

SUPRAVULGAR, *adj.* Lat. *supra* and *vulgaris*. Above the vulgar.

SUPREME', *adj.* } Lat. *supremus*. Highest;
SUPREMACY, *n. s.* } highest in dignity, autho-
SUPREME'LY, *adv.* } rity and excellence: the
 noun substantive and adverb corresponding.

SUPREMACY. According to the Roman Catholics, St. Peter was not only the head of the apostolic college, but the pastor of the universal church. The Roman pontiff is the successor of this prince of the apostles, and, like him, has authority and jurisdiction over the whole church, all believers, without exception, owing him respect and obedience. The council of Trent declared that the sovereign pontiff is the vicar of God, upon earth, and has supreme power over all the church. The extent of the authority thus assumed by the pope, is different in different countries, and the whole doctrine of the papal supremacy is of course rejected by the Protestant, Greek and other churches. In 1534, Henry VIII. assumed the title of the only supreme head on earth, of the church of England. The *oath of supremacy* (that is, of renunciation of the papal supremacy), with the oath of abjuration, was formerly required to be taken by all persons in office, and might be tendered, by two justices of the peace, to all persons suspected of disaffection in England. Some modifications of the law requiring this oath were made in 1793 (see *Catholic Emancipation*); but it was still, with the declaration against transubstantiation, the invocation of saints, and the sacrifice of the mass, requisite for a qualification for sitting and voting in parliament, and for holding certain offices, until the passage of the Catholic relief bill. This bill repeals all former acts on the subject, and requires of a Roman Catholic peer, or member of the house of commons, &c., besides the oath of allegiance and abjuration, the following oath of supremacy: I do declare that it is not an article of my faith, and that I do reject, renounce and abjure the opinion, that princes excommunicated or deprived by the pope, or any other authority of the see of Rome, may be deposed or murdered by their subjects, or by any person whatsoever; and I do declare that I do not believe that the pope of Rome, or any other foreign prince, prelate, person, state or potentate, hath, or ought to have any temporal or civil jurisdiction, power, superiority or pre-eminence, directly or indirectly within this realm.

SUR, or **SHUR**, in ancient geography a desert of Arabia Petræa, extending between Palestine and the Arabian Gulf; into which the Israelites, after marching through the Red Sea, first came.—Exod. xv. 22. In Numbers xxxiii. 8, it is said that from the sea they went three days' journey into the wilderness of Etham; whence some conclude that Etham and Shur are the same wilderness; or only differ as a part from the whole, Shur being the general name, and Etham that part of it lying nearest to the place of encampment of the same name. As to the route which the Israelites followed, in their passage through the Red Sea, Mr. Bryant has given an account in his work on the Plagues of Egypt. Shur is now called Corondel.

SURA, in anatomy, the lesser bone of the calf of the leg.

SURA, in geography, a river of Norway, in Drontheim, which runs into the North Sea, opposite Christiansand.

SURADDITION, *n. s.* Sur and addition. Something added to the name.

He served with glory and admired success,
 So gained the *suraddition*, Leonatus.

Shakespeare. Cymbeline.

SUR'AL, *adj.* Lat. *sura*. Being in the calf of the leg.

He was wounded in the inside of the calf of his leg, into the *sural* artery.

Wiseman's Surgery.

SUR'ANCE, *n. s.* From **SURE**. Warrant; security; assurance.

Give some *surance* that thou art revenge;
 Stab them, or tear them on thy chariot wheels.

Shakespeare.

SURAT, one of the largest, if not the very largest city of Hindostan, is situated on the south side of the Tuptic River, about twenty-eight miles from its junction with the sea, although its trade has unavoidably suffered by the proximity of Bombay. In 1796 one estimate, according to major Hamilton, raised the population of Surat so high as 800,000 souls; but another reduced it to 600,000, which probably exceeds the actual number. In 1807 this city contained 1200 parsees of the mobid or sacerdotal class, and about 12,000 of the behdeen, or laity parsees. Large ships do not ascend the river, but cast anchor about twenty miles below the town. The harbour, on the whole, is not commodious; it is, however, one of the best on this coast during the prevalence of the north-east and north-west winds; and the anchorage is only dangerous with winds from the south and west. A large quantity of cotton was formerly exported from Surat direct to China; but much the greater portion is now sent by the way of Bombay. The cotton trade from this part of India to China is of a recent date, and did not commence earlier than 1775, at which era there was a greater number of ships belonging to Surat than there is now to Bombay. The import and export trade which it still retains is much engrossed by the Arabian and Boras merchants.

Surat is mentioned in the Ramayuna, a Hindoo poem of great antiquity. After the discovery of the passage to the east by the Cape of Good Hope, it was much frequented by European vessels, who exported hence pearls, diamonds, ambergris, civet, musk, gold, silks, and cottons of every description, spices, fragrant woods, indigo, saltpetre, and all other objects of Indian traffic. Hence also great multitudes of pilgrims embarked for Arabia; in which account Surat was always considered by the Mahometans of Hindostan as one of the gates of Mecca. In 1612 captain Best received permission to settle an English factory here, where he left ten persons with a stock of £4000 to purchase goods. The Dutch did not visit Surat until 1617. The French carried on a considerable but losing trade with Surat during the first years of the eighteenth century; and, having contracted debts to the natives, deserted it altogether. Some time afterwards, in 1714, a company was formed at St. Maloes, which despatched ships to the East Indies; but these were seized and sequestered at Surat, to liquidate the debts of the former com-

pany. In January 1664 the Maharattas, under Sevajee, made a sudden attack on Surat, when the governor shut himself up in the castle, and the inhabitants fled. In this emergency Sir George Oxinden, the chief, and the rest of the Company's servants, shut themselves up in the factory with the Company's property, valued at £80,000; and, having fortified it as well as the time would allow, called in the ships' crews to assist in its defence. When attacked, they made so vigorous a resistance, that they not only preserved the factory, but the greatest part of the town; for which they received the thanks of the Mogul commander. Surat was attacked, and partially pillaged, by the Mahrattas in 1670, and afterwards in 1702. In April, 1707, it was again invested by them; but they were unable to make any progress. Moyen ud Deen, the ancestor of the present nabob, was an adventurer who, in 1748, possessed himself of the castle: his successors, Cuttub ud Deen in 1763, Nizam ud Deen in 1792, and Nassir ud Deen in 1800, were all invested by the East India Company. On the 13th of May, in that year, a treaty was concluded with Nassir ud Deen, the reigning nabob, by which he agreed that the management of the city and district of Surat, and the administration of civil and criminal justice, should be exclusively vested in the British: the latter engaging to pay the nabob and his heirs one lack of rupees annually, and also a proportion of one-fifth of the surplus annual revenue, deducting all charges. By the treaty of 1803 the Mahrattas were compelled to abandon all their claims on this city. Since this period the country has been much cleared of robbers, and every way improved. Travelling distance from Bombay 177 miles; from Poonah 243; from Oojain 309; from Delhi 756; and from Calcutta, by Nagpoor, 1238 miles.

SURBATE, *v. a.* Fr. *solbatir*. To bruise and batter the feet with travel; harass; fatigue. Not used.

Their march they continued all that night, the horsemen often alighting, that the foot might ride, and others taking many of them behind them; however they could not but be extremely weary and *surbated*.

Chalky land *surbates* and spoils oxen's feet.

Clarendon.
Mortimer.

SURBET. The *part. pass.* of *surbate*, which Spenser seems to have used for *surbate*.

A bear and tiger being met
In cruel fight on Lybick ocean wide,
Espy a traveller with feet *surbet*,
Whom they in equal prey hope to divide. *Spenser.*

SURCEASE, *v. n., v. a., & n. s.* Fr. *sur* and *cesser*; Lat. *cesso*. To be at an end; stop; leave off: cease: put an end to: cessation; stop.

All pain hath end, and every war hath peace;
But mine no price, nor prayer, may *surcease*.

Spenser.

To fly together from God, to despair that creatures unworthy shall be able to obtain any thing at his hands, and under that pretence to *surcease* from prayers, as bootless or fruitless offices, were to him no less injurious than pernicious to our own souls.

Hooker.

It might very well agree with your principles, if your discipline were fully planted, even to send out

your writs of *surcease* unto all courts of England for the most things handled in them. *Id.*

Small favours will my prayers increase:

Granting my suit you give me all;

And then my prayers must needs *surcease*;

For I have made your godhead fall. *Donne.*

Nor did the British squadrons now *surcease*

To gall their foes o'erwhelmed. *Philips.*

SURCHARGE, *v. a. & n. s.* Fr. *surcharger*. To overburden; overload: burden added to burden; overburden.

They put upon every portion of land a reasonable rent, which they called *Romescot*, the which might not *surcharge* the tenant or freeholder.

Spenser on Ireland.

Tamas was returned to Tauris, in hope to have suddenly surprised his enemy, *surcharged* with the pleasures of so rich a city.

Knolles's History of the Turks.

The air, after receiving a charge, doth not receive a *surcharge*, or greater charge, with like appetite as it doth the first.

Bacon's Natural History.

More removed,

Let heaven *surcharged* with potent multitude,

Might hap to move new broils.

Milton's Paradise Lost.

When graceful sorrow in her pomp appears,

Sure she is dressed in Melesinda's tears:

Your head reclined, as hiding grief from view,

Droops like a rose *surcharged* with morning dew.

Dryden.

The moralists make this raging of a lion to be a *surcharge* of one madness upon another.

L'Étrange.

SURCHARGE OF COMMON is a disturbance of common pasture, by putting more cattle therein than the pasture and herbage will sustain, or the party hath a right to do. This injury can only happen where the common is appendant or appurtenant, and of course limitable by law; or where, when in gross, it is expressly limited and certain; for where a man hath common in gross, sans nombre, or without stint, he cannot be a *surcharge*. In this case, indeed, there must be left sufficient for the lord's own beasts. The usual remedies for *surcharging* the common are by the lord's distraining the surplus number, or by his bringing an action of trespass, or by a special action on the case, in which any commoner may be plaintiff. The ancient and most effectual method of proceeding is by writ of *admeasurement* of pasture.

SURCHARGE OF THE FOREST is when a commoner puts more beasts in the forest than he has a right to do. See **FOREST**.

SURCHARGE, WRIT OF SECOND, de secunda superoneratione, is given by the stat. of Westm. 2. 13. Edw. I. cap. 8, when, after the *admeasurement* of pasture hath ascertained the right, the same defendant *surcharges* the common again; and thereby the Sheriff is directed to enquire by a jury whether the defendant has in fact again *surcharged* the common; and, if he has, he shall then forfeit to the king the supernumerary cattle put in, and also shall pay damages to the plaintiff.

SURCINGLE, *n. s.* Lat. *sur* and *cingulum*. A girth with which the burden is bound upon a horse; the girdle of a cassock.

Justly he chose the *surcingle* and gown. *Marscl.*

SUR/CLÉ, *n. s.* Lat. *surculus*. A shoot; a twig; a sucker. Not in general use.

It is an arboreous exerescence, or superplant, which the tree cannot assimilate, and therefore sprouteth not forth in boughs and *surcles* of the same shape unto the tree. *Browne.*

The basilica dividing into two branches below the cubit, the outward sendeth two *surcles* unto the thumb. *Id.*

SUR/COAT. *n. s.* Old Fr. *surcot*. Sur and coat. A short coat worn over the rest of the dress.

The honourable abillaments, as robes of state, parliament-robes, the *surcoat* and mantle. *Camden.*

That day in equal arms they fought for fame; Their swords, their shields, their *surcoats* were the same. *Dryden.*

The **SURCOAT** is a coat of arms worn over the body armour. It is properly a loose thin taffety coat, with arms embroidered or pointed on it; such as worn by heralds; and was anciently also used by military men over their armour to distinguish them.

SURCULI, in botany, the middle ramifications of the ribs of a leaf.

SURCULUS, a shoot; a set or slip; ascion or graft; a young twig or branch of a tree.

SURD NUMBER, in arithmetic and algebra, any number or quantity that is incommensurable to unity; otherwise called an irrational number or quantity. See **ALGEBRA**.

SURE, *adj. & adv.* } Fr. *sur*; of Lat. *secu-*
SUREFOOTED, } *rus*. Firm; certain;
SURELY, *adv.* } unfailling; infallible;

SURENESS, *n. s.* } hence confident; undoubting; steady: it is also used adverbially for certainty; without doubt: *surefooted* is of firm or steady feet or tread: the adverb and noun substantive correspond with *sure*.

In the day that thou eatest thereof thou shalt *surely* die. *Genesis.*

He that walketh righteously, walketh *surely*. *Psalms.*

The testimony of the Lord is *sure*, and giveth wisdom unto the simple. *Id. xix. 7.*

Thy kingdom shall be *sure* unto thee, after that thou shalt have known that the heavens do rule. *Dan. iv. 26.*

Friar Lawrence made them both; Him he knew well, and guessed that it was she: But being masked, he was not *sure* of it. *Shakspeare.*

Thou the garland wearest successively; Yet though thou standest more *sure* than I could do, Thou art not firm enough. *Id. Henry IV.*

I wish your horses swift and *sure* of foot, And so I do commend you to their backs. *Id. Macbeth.*

Something, *sure*, of state Hath wrapp'd his clear spirit. *Shakspeare.*

I was in *sure* bands both their hands and feet, And cast them under hatches. *Chapman.*

True earnest sorrows, rooted miseries, Anguish in grain, vexations ripe and blown, *Surefooted* griefs, solid calamities. *Herbert.*

The subtle ague, that for *sureness* sake Takes its own time the assault to make. *Cowley.*

The youngest in the morning are not *sure* That 'till the night their life they can secure. *Denham.*

Who knows, Let this be good, whether our angry foe

Can give it, or will ever? How he can Is doubtful; that he never will, is *sure*.

Milton's Paradise Lost.
Let no man seek what may befall;
Evil he may be *sure*. *Milton.*

Thou *surely* hadst not come sole fugitive. *Id.*
Virtue, dear friend, needs no defence:

The *surest* guard is innocence. *Roscommon.*
They have a nearer and *surer* way to the felicity of life, by tempering their passions, and reducing their appetites. *Tennle.*

A peace cannot fail, provided we make *sure* of Spain. *Id.*

They would make others on both sides *sure* of pleasing, in preference to instruction.

Dryden's Dufresnoy.
Revenge is now my joy: he's not for me,
And I'll make *sure* he ne'er shall be for thee. *Dryden.*

He bade me make *sure* of the bear, before I sell his skin. *L'Estrange.*

Our coin beyond sea is valued according to the silver in it: sending it in bullion is the safest way, and the weightiest is *sure* to go. *Locke.*

Doubting thus of innate principles, men will call pulling up the old foundations of knowledge and certainty: I persuade myself that the way I have pursued, being conformable to truth, lays those foundations *surer*. *Id.*

Sure the queen would wish him still unknown;
She loaths, detests him, flies his hated presence. *Smith.*

He that created something out of nothing, *surely* can raise great things out of small. *South.*

Make Cato *sure*, and give up Utica,
Cæsar will ne'er refuse thee such a trifle. *Addison.*

Her looks were flushed, and sullen was her mien,
That show'd the virgin goddess, had she been
Aught but a virgin, must the guilt have seen. *Id.*

He diverted himself with the speculation of the seed of coral; and for more *sureness* he repeats it. *Woodward.*

They have reason to make all actions worthy of observation, which are *sure* to be observed. *Atterbury.*

Objects of sense would then determine the views of all such, to be *sure*, who conversed perpetually with them. *Id.*

Though the chymist could not calcine the caput mortuum, to obtain it fixed salt, to be *sure*, it must have some. *Arbutnot.*

The curious have thought the most minute affairs of Rome worth notice; and *surely* the consideration of their wealth is at least of as great importance as grammatical criticisms. *Id.*

If you find nothing new in the matter, I am *sure* much less will you in the style. *Wake.*

Surely we may presume, without affecting to sit in the seat of God, to think some very fallible men liable to errors. *Waterland.*

To prove a genuine birth,
On female truth assenting faith relies:
Thus, manifest of right, I build my claim,
Sure founded, on a fair maternal fame. *Pope's Odyssey.*

Be silent always, when you doubt your sense;
And speak, though *sure*, with seeming diffidence. *Pope.*

Sure, upon the whole, a bad author deserves better usage than a bad critick. *Id.*

SURENAS, a celebrated Parthian general, who defeated the Romans under Crassus, the father and son, and gave the old avaricious Roman what he merited. See **PARTHIA**.

SURENHUSIUS (William), a learned Hebraean, of the university of Amsterdam, who flourished in the end of the seventeenth and beginning of the eighteenth centuries. He published an edition of the Mischna, with notes of his own, and a Latin version, in 1703, in three volumes folio. It contains also the commentaries of the rabbins Maimonides and Bartenora.

SURETY, *n. s.* } Fr. *sureté*, From SURE.
SURETYSHIP. } Certainty; indubitableness; ratification; confirmation; security against loss or damage; hence a hostage; bondsman; pledge: the office of a surety; the act of being bound for another.

Know of a *surety* that thy seed shall be a stranger. *Gen. xv.*

I will be *surety* for him; of my hand shalt thou require him. *Id. xliiii. 9.*

He that hateth *suretyship* is sure. *Solomon.*
There the princesses determining to bathe, thought it was so privileged a place as no body durst presume to come hither; yet, for the more *surety*, they looked round about. *Sydney.*

She called the saints to *surety*,
That she would never put it from her finger,
Unless she gave it to yourself. *Shakspeare.*

There remains unpaid
A hundred thousand more, in *surety* of the which
One part of Aquitain is bound to us. *Id.*

That you may well perceive I have not wronged you,

One of the greatest in the Christian world
Shall be my *surety*. *Id. All's Well that ends Well.*

Idly, like prisoners, which whole months will swear
That only *suretyship* hath brought them there. *Donne.*

Yet be not *surety*, if thou be a father;
Love is a personal debt; I cannot give
My children's right, nor ought he take it. *Herbert.*

All, in infancy, are by others presented with the desires of the parents, and intercession of *sureties*, that they may be early admitted by baptism into the school of Christ. *Hammond.*

If here not cleared, no *suretyship* can bail
Condemned debtors from the' eternal gaol. *Denham.*

We our state
Hold, as you yours, while our obedience holds;
On other *surety* none. *Milton.*

Hath not the greatest slaughter of armies been effected by stratagem? And have not the fairest estates been destroyed by *suretyship*? *South.*

SURETY OF THE PEACE AND GOOD BEHAVIOUR is considered by Blackstone as a species of preventive justice; by obliging persons, whom there is a probable ground to suspect of future misbehaviour, to stipulate with, and to give full assurance to the public, that such offence as is apprehended from them shall not happen; through the means of pledges or sureties for keeping the peace, or for their good behaviour.—4 Comm. c. 18.

I. By the Saxon constitution these sureties, by means of king Alfred's wise institution of decandaries or frankpledges, were always at hand, the whole neighbourhood or tithing of freemen being mutually pledges for each other's good behaviour. But this great and general security being now fallen into disuse, and neglected, there hath succeeded to it the method of making suspected persons find particular and special securities for their future conduct; of which we find mention in the laws of king Edward the

Confessor; 'tradat fidejussores de pace et legalitate tuendâ,' cap 18.

This security, therefore, at present consists in being bound with one or more sureties, in a recognizance or obligation to the king, entered on record, and taken in some court, or by some judicial officer; whereby the parties acknowledge themselves to be indebted to the crown in the sum required (for instance £100) with condition to be void and of none effect, if the party shall appear in court on such a day: and in the mean time shall keep the peace; either generally towards the king, and all his liege people; or particularly, also, with regard to the person who craves the security. Or, if it be for the good behaviour, then on condition that he shall demean and behave himself well (or be of good behaviour), either generally or specially for the time therein limited, as for one or more years, or for life. This recognizance, if taken by a justice of the peace, must be certified to the next sessions, in pursuance of the stat. 3 Hen. VII. c. 1, and if the condition of such recognizance be broken, by any breach of the peace in the one case, or any misbehaviour in the other, the recognizance becomes forfeited or absolute; and being extracted or extracted (taken out from among the other records), and sent up to the exchequer, the party and his sureties, having now become the king's absolute debtors, are sued for the several sums in which they are respectively bound.—4 Comm. c. 8.

II. Any justices of the peace, by virtue of their commission, or those who are ex officio conservators of the peace, may demand such security according to their own discretion: but a secretary of state, or a privy counsellor, is not, ex officio, such conservator, and therefore cannot bind to the peace or good behaviour.—11. St. Tr. 317. Or it may be granted at the request of any subject, upon due cause shown, provided such demandant be under the king's protection, for which reason it has been formerly doubted whether Jews, Pagans, or persons convicted of a præmunire, were entitled thereto.—1. Hawk. P. C. Or, if the justice is averse to act, it may be granted by a mandatory writ, called a supplicavit, issuing out of the court of king's bench or chancery: which will compel the justice to act, as a ministerial and not as a judicial officer; and he must make a return to such writ, specifying his compliance, under his hand and seal. But this writ is seldom used; for, when application is made to the superior courts, they usually take recognizances there, under the directions of the stat. 21, Jac. I. c. 8. And indeed a peer or peeress cannot be bound over in any other place than the courts of king's bench or chancery; though a justice of the peace has a power to require sureties of any other person, being compos mentis, and under the degree of nobility, whether he be a fellow justice or other magistrate, or whether he be merely a private man. Wives may demand it against their husbands: so peeresses against their lords; or husbands, if necessary, against their wives. But feme covert, and infants under age, ought to find security by their friends only, and not to be bound themselves: for they are incapable of en-

gaging themselves to answer any debt; which is the nature of these recognizances or acknowledgments. See RECOGNIZANCE.

If the person, against whom it is demanded, be present, the justice of the peace may commit him immediately, unless he offers sureties; and à fortiori he may be commanded to find sureties, and be committed for not doing it. But, if he is absent, a warrant for committing him cannot be granted, till a warrant is issued commanding him to find sureties; and this warrant, which must be under seal, ought to show the cause for which it is granted and at whose suit.

Any justice of the peace may, ex officio, bind all those to keep the peace, who, in his presence, make any affray; or threaten to kill or beat another; or contend together with hot and angry words; or go about with unusual weapons or attendance, to the terror of the people; and all such as he knows to be common barrators; and such as are brought before him by the constable for a breach of the peace in his presence; and all such persons as, having been before bound to the peace, have broken it and forfeited their recognizances. Also, wherever any private man hath just cause to fear that another will burn his house, or do him a corporal injury, by killing, imprisoning, or beating him, or that he will procure others so to do, he may demand surety of the peace against such person: and every justice of the peace is bound to grant it, if he who demands it will make oath that he is actually under fear of death or bodily harm; and will show that he has just cause to be so by reason of the other's menaces, attempts, or having lain in wait for him; and will also farther swear that he does not require such surety out of malice or for mere vexation. This is called swearing the peace against another: and, if the party does not find such sureties as the justice in his discretion shall require, he may immediately be committed till he does.—1 Hawk. P. C. c. 60. Surety of the peace may be demanded by a wife, if her husband gives her unreasonable correction.—Moor. 874: Godb. 215: F. N. B. 80. Surety of the peace ought not to be granted to a man for fear of danger to his servant or cattle. It hath, however, been said that a man may have the surety of the peace against one who threatens to hurt his wife or child.—Dalt. 266. The surety of the peace ought not to be granted for any past battery, unless there is a fear of some present or future danger: but the offender must, in such case, be punished by action or indictment.—Dalt. 266. The demand of the surety of the peace ought to be soon after the cause of fear; for the suffering much time to pass before it is demanded shows that the party has been under no great terror. It is said, the fear of one cannot be the fear of another: and therefore every recognizance must be separate. But in Mich. 23 Geo. II. B. R. the court allowed three women to file joint articles of the peace against three men.—R. v. Nettle, cited 1 Hawk. P. C. c. 60. § 5, Leach's note. Although the fact from which the fear arises be pardoned, the court of king's bench will receive it as a ground to grant the security upon.—Stra. 473.

At the common law, the oath of the party was

a sufficient ground for the court of king's bench to grant the surety of the peace; but this cannot be done since the stat. 21 Jac. I. c. 8, unless articles of the peace are exhibited in court, upon motion in open court.

The court will not permit the truth of the allegations to be controverted by the defendant, but will order security to be taken immediately, if no objections arise upon the face of the articles themselves. But if, on application for the assistance of the court to enforce the subsequent process, the articles should manifestly appear, from the corroborated affidavit of the defendant, to have been a malicious, voluntary, and gross perjury, the court will resist the application, and commit the offender. When surety of the peace is granted by the court of king's bench, if a supersedeas comes from the court of chancery to the justices of that court, their power is at an end; and the party as to them discharged.

Justices of peace are empowered by the stat. 34 Edw. III. c. 1 to bind over to the good behaviour, towards the king and his people, all them that be not of good fame, wherever they be found, to the intent that the people be not troubled nor endangered, nor the peace diminished, nor merchants and others, passing by the high-ways of the realm, be disturbed nor put in peril, which may happen by such offenders. Under the general words of this expression, that be not of good fame, it is holden that a man may be bound to his good behaviour for causes of scandal contra bonos mores, as well as contra pacem; as for haunting bawdy-houses with women of bad fame; or for keeping such women in his own house; or for words tending to scandalize the government; or in abuse of the officers of justice, especially in the execution of their office. Thus also a justice may bind over all night-walkers; eaves-droppers; such as keep suspicious company, or are reported to be pilferers or robbers; such as sleep in the day and wake in the night; common drunkards; whore-masters; the putative fathers of bastards; cheats; idle vagabonds; and other persons whose misbehaviour may reasonably bring them within the general words of the statute, as persons not of good fame; an expression, it must be owned, of so great a latitude, as leaves much to be determined by the discretion of the magistrate himself. But, if he commits a man for want of sureties, he must express the cause thereof with convenient certainty; and take care that such cause be a good one.—1 Hawk, P. C. c. 61: 4 Comm. 256.

III. A recognizance may be discharged, either by the demise of the king, to whom the recognizance is made; or by the death of the principal party bound thereby, if not before forfeited; or by order of the court to which such recognizance is certified by the justices (as the quarter-sessions, assizes, or king's bench) if they see sufficient cause: or in case he at whose request it was granted, if granted upon a private account, will release it, or does not make his appearance to pray that it may be continued. Such recognizance for keeping the peace, when given, may be forfeited by any actual violence, or even an assault, or menace, to the person of him who

demanded it, if it be a special recognizance; or, if the recognizance be general, by any unlawful action whatsoever, that either is, or tends to a breach of the peace; or, more particularly, by any one of the many species of offences against the public peace; or by any private violence committed against any of his majesty's subjects. But a bare trespass upon the lands or goods of another, which is a ground for a civil action, unless accompanied by a wilful breach of the peace, is no forfeiture of the recognizance. Neither are mere reproachful words, as calling a man a knave or liar, any breach of the peace, so as to forfeit one's recognizance (being looked upon to be merely the effect of unmeaning heat and passion), unless they amount to a challenge to fight.—1 Hawk. P. C. c. 60 : 4 Comm. 255, 6.

By the stat. 3 Hen. VII. c. 1, beforementioned, it is enacted, 'That if the party who is called at a sessions of the peace, upon a recognizance of keeping the peace, makes default, his default shall be then and there recorded, and the same recognizance, with the record of the default, be sent and certified into the chancery, or before the king in his bench, or into the king's exchequer.' He who is bound to keep the peace, and to appear at the sessions, must appear there, and record his appearance; otherwise his recognizance is forfeited. And, although the party who craved the surety of the peace comes not to pray that it may be continued, the justices may in their discretion order it to be continued till another sessions.

But if an excuse, which is judged by the court to be a reasonable one, is given for the non-appearance of a party, it seems that the court is not bound peremptorily to record his default, but may discharge the recognizance, or respite it till the next sessions. A recognizance for keeping the peace may be forfeited by any actual violence to the person of another, whether it be done by the party bound, or others by his procurement. In support of a rule to stay proceedings in a *scire facias*, upon a recognizance for keeping the peace, it was said that the assault, which had been made, was not upon him at whose request the surety of the peace was granted, but upon another person. It was held that this makes no difference; and the rule was discharged. MS. Rep. Rex v. Stanley and his bail, Trin. 27 Geo. II. But a recognizance for keeping the peace is not forfeited where an officer, having a warrant against one who will not suffer himself to be arrested, beats or wounds him in the attempt to take him. So it is not forfeited, if a parent in a reasonable manner chastises his child; a master his servant, being actually in his service at the time; a schoolmaster his scholar; a gaoler his prisoner; a husband his wife.

It has been held, that a recognizance for the peace may be forfeited by any treason against the person of the king, or by an unlawful assembly in *terrorem populi*.—Lamb. 115, 1 Hawk. P. C. c. 60. Words which tend directly to a breach of the peace as challenging a man to fight, or threatening to beat one who is present, amount to a forfeiture of such recognizance. A recognizance is likewise forfeited by threatening to beat a person who is absent, if the party who has so threatened,

does afterward lie in wait to beat him. A court of quarter-sessions cannot in any case proceed against the parties, for a forfeiture of a recognizance for keeping the peace; but the recognizance must be sent into some of the king's courts in Westminster Hall. All proceedings upon a forfeited recognizance must be by *scire facias*, and not by indictment; because, where a *scire facias* is brought, the parties have an opportunity of pleading any matter in their discharge.

The usual practice of a court of quarter-sessions is to continue a recognizance for keeping the peace from sessions to sessions until the court thinks proper to discharge it. It is the constant course of the court of king's bench to take a recognizance for twelve months; and, if no indictment is within that time preferred against the party bound to keep the peace, it may, at the expiration thereof, be discharged. This seems also to be the practice of the court of chancery. A recognizance for the good behaviour may be forfeited by all the same means as one for the security of the peace may be; and also by some others; as by going armed with unusual attendance, to the terror of the people; by speaking words tending to sedition; or by committing any of those acts of misbehaviour which the recognizance was intended to prevent. But not by barely giving fresh cause of suspicion of that which perhaps may never actually happen; for, though it is just to compel suspected persons to give security to the public against misbehaviour that is apprehended, yet it would be hard upon such suspicion, without the proof of any actual crime, to punish them by a forfeiture of their recognizance.

SURF, a term used by seamen to express a peculiar swell and breaking of the sea upon the shore. It sometimes forms but a single range along the shore, and at others three or four, behind one another, extending half a mile out to sea. The surf begins to assume its form at some distance from the place where it breaks, gradually accumulating as it moves forward, till it gain, not uncommonly, in places within the limits of the trade-winds, a height of fifteen or twenty feet, when it overhangs at top, and falls like a cascade with great force and a prodigious noise. Countries where surfs prevail require boats of a particular construction, very different from the greater part of those which are built in Europe. In some places surfs are great at high, and in others at low water; but are uniformly most violent during the spring tides. It is not easy to assign the cause of surfs. That they are affected by the winds can hardly be questioned; but that they do not proceed from the immediate operation of the wind, in the places where they happen, is evident from this circumstance, that the surf is often highest and most violent where there is least wind, and vice versa. On the coast of Sumatra the highest are experienced during the south-east monsoon, which is never attended with such gales as the north-west. As they are most general in the tropical latitudes, Mr. Marsden, who seems to have paid much attention to the subject, attributes them to the trade-winds which prevail at a distance from shore between the parallels of 30° north and south, whose uni-

form and invariable action causes a long and constant swell, that exists even in the calmest weather, about the line, towards which its direction tends from either side. This swell, when a squall happens or the wind freshens up, will for the time have other subsidiary waves on the extent of its surface, breaking often in a direction contrary to it, and which will again subside as a calm returns, without having produced on it any perceptible effect. Sumatra, though not continually exposed to the south-east trade-wind, is not so distant but that its influence may extend to it: and accordingly at Poolo Pesang, near the southern extremity of the island, a constant southerly sea is observed, even after a strong north-west wind. This incessant and powerful swell rolling in from an ocean, open even to the pole, seems an agent adequate to the prodigious effects produced on the coast; whilst its very size contributes to its being overlooked. It reconciles almost all the difficulties which the phenomena seem to present, and in particular it accounts for the decrease of the surfs during the north-west monsoon, the local wind then counteracting the operation of the general one; and it is corroborated by an observation, that the surfs on the Sumatran coast ever begin to break at their southern extreme, the motion of the swell not being perpendicular to the direction of the shore. This explanation of the phenomena is certainly plausible; but, as the author candidly acknowledges, objections may be urged to it. The trade-winds, and the swell occasioned by them, are remarkably steady and uniform; but the surfs are much the reverse. How then comes a uniform cause to produce unsteady effects? In the opinion of our author, it produces no unsteady effects. The irregularity of the surfs, he says, is perceived only within the remoter limits of the trade-winds. But the equatorial parts of the earth performing their diurnal revolution with greater velocity than the rest, a larger circle being described in the same time, the water thereabout, from the stronger centrifugal force, may be supposed more buoyant; to feel less restraint from the sluggish principle of matter; to have less gravity; and therefore to be more obedient to external impulses of every kind, whether from the winds or any other cause.

SURFACE, *n. s.* Fr. *sur* and *face*. Superficies; outside: accented by Milton on the last syllable.

Which of us who beholds the bright *surface*
Of this ethereous mold, whereon we stand. *Milton.*

Errors like straws upon the *surface* flow;
He who would search for pearls must dive below.
Dryden.

All their *surfaces* shall be truly plain, or truly spherical, and look all the same way, so as together to compose one even *surface*. *Newton's Opticks.*

SURFACE. See **SUPERFICIES**.

SURFEIT *v. a., v. n., &* French *sur* and **SURFEITER**, *n. s.* [*n. s.*] *faire*, to do more than enough; to overdo. To feed with meat or drink to satiety and sickness; to cram: to be full; to satisfy: a surfeiter is he who so feeds; a glutton: surfeit-water, that which cures surfeits.

The *surfeited* grooms

Do mock their charge with snotes. *Shakspeare.*
When we are sick in fortune, often the *surfeits* of our own behaviour, we make guilty of our disasters the sun, the moon, and stars. *Id. King Lear.*

They are as sick that *surfeit* with too much, as they that starve with nothing. *Id. Merchant of Venice.*

Now comes the sick hour that his *surfeit* made;
Now shall he try his friends that flattered him.
Id. Richard II.

I did not think

This amorous *surfeiter* would have donned his helm
For such a petty war. *Id. Antony and Cleopatra.*
Surfeits many times turn to purges, both upwards and downwards. *Bacon's Natural History.*

Why, disease, dost thou molest

Ladies, and of them the best?

Do not men grow sick of rites,

To thy altars, by their nights,

Spent in *surfeits*? *Ben Jonson.*

Peace, which he loved in life, did lend
Her hand to bring him to his end;
When age and death called for the score,
No *surfeits* were to reckon for. *Crashaw.*

Though some had so *surfeited* in the vineyards,
and with the wines, that they had been left behind,
the generosity of the Spaniards sent them all home.
Clarendon.

Our father

Has ta'en himself a *surfeit* of the world,
And cries, it is not safe that we should taste it.

Orway.

They must be let loose to the chilaish play the
fancy, which they should be weaned from, by being
made to *surfeit* of it. *Locke.*

A little cold distilled poppy-water, which is the true *surfeitwater*, with ease and abstinence, often ends distempers in the beginning. *Id.*

SURFEIT, in medicine, is a sickness with a sensation of a load at the stomach, usually proceeding from some error in diet, either with regard to the quantity or quality of the food taken. Sometimes, however, a surfeit is only a plethora from indolence and full but proper feeding; in which case perspiration is defective; and eruptions form themselves on the skin. A surfeit from animal food, as muscles, putrid flesh, &c., is best remedied by the use of vegetable acids, which may be taken diluted with water, a vomit being premised, and this even though a vomiting and purging both attend. When an excess of feeding is the cause, the *primæ viæ* being evacuated, and the nature of the plethora attended to, that the load may be properly evacuated, the indication of the cure will be, to recover the perspiratory discharge, consistent with which diuretics may be used in preference to medicines which produce any other evacuation. But the most natural and effectual remedy for a surfeit is abstinence, and temperance afterwards.

SURFEIT, in farrery. See **FARRIERY**.

SURGE, *n. s. & v. a.* Lat. *surgo*. A swelling sea; wave rolling above the general surface of the water: to swell; rise on high.

It was formerly famous for the unfortunate loves of Hero and Leander, drowned in the uncompassionate *surges*. *Sandys.*

From midst of all the main
The *surging* waters like a mountain rise. *Spenser.*
The realm was left like a ship in a storm, amidst all the raging *surges*, unrul'd and undirected of any. *Id.*

The wind-shaked *surge*, with high and monstrous main,
 Seems to cast water on the burning bear,
 And quench the guards of the ever-fired pole:
 I never did like molestation view
 On the enchafed flood.

Shakspeare.

The serpent moved, not with intended wave,
 Prone on the ground as since; but on his rear,
 Circular base of rising folds, that towered
 Fold above fold, a *surging* maze!

Milton.

The sulph'rous hail
 Shot after us in storm, o'erblown hath laid
 The fiery *surges*, that from the precipice
 Of heaven received us falling.

H.

He sweeps the skies, and clears the cloudy north:
 He flies aloft, and with impetuous roar
 Pursues the foaming *surges* to the shore.

Dryden.

Thetis, near Ismena's swelling flood,
 With dread beheld the rolling *surges* sweep
 In heaps his slaughtered sons into the deep.

Pope.

Do publick or domestick cares constrain
 This toilsome voyage o'er the *surgy* main?

Id.

SURGEON, *n. s.* } Corrupted from chi-
 SURGERY. } rurgeon. One who cures
 by manual operation; or one whose duty it is to
 act in external maladies by the direction of the
 physician: the act of curing by manual operation.

The wound was past the cure of a better *surgeon*
 than myself, so as I could but receive some few of her
 dying words.

Sidney.

It would seem very evil *surgery* to cut off every
 unsound part of the body, which, being by other
 due means recovered, might afterwards do good ser-
 vice.

Spenser.

Strangely visited people,
 The mere despair of *surgery*, he cures.

Shakspeare. Macbeth.

They are often tarred over with the *surgery* of our
 sheep, and would you have us kiss tar? *Shakspeare.*

Tho' most were sorely wounded, none were slain;
 The *surgeons* soon despoiled them of their arms,
 And some with salves they cure.

Dryden.

A SURGEON, or CHIRURGEON, is one who pro-
 fesses the art of surgery. In England there are
 two distinct companies of surgeons now occupy-
 ing the science or faculty of surgery; the one
 company called barbers, the other surgeons, which
 latter are not incorporated. The two are united
 to sue, and be sued, by the names of masters or
 governors and commonalty of the mystery of
 barbers and surgeons of London, 32 Henry VIII.
 c. 42. No person using any barberry or shaving,
 in London, shall occupy any surgery, letting of
 blood, or other matter; drawing of teeth only ex-
 cepted. And no person using the mystery or craft
 of surgery shall occupy or exercise the seat or craft
 of barberry, or shaving, neither by himself, nor any
 other for his use, 32 Henry VIII. c. 42. By the
 same statute, surgeons are obliged to have signs at
 their doors. Under the old French government,
 the French chirurgiens, being refused to be ad-
 mitted into the universities (although their art is
 a branch of medicine), on pretence of its border-
 ing a little on butchery or cruelty, associated
 themselves into a brotherhood, under the protec-
 tion of St. Cosmus and St. Damian; on which
 account, according to the laws of their institution,
 they were obliged to dress and look to wounds
 gratis the first Monday of each month. They
 distinguished between a chirurgieon of the long
 robe and a barber chirurgieon. The first had
 studied physic, and was allowed to wear a gown.
 The skill of the other, besides what relates to the
 management of the beard, was supposed to be
 confined to the more simple and easy operations
 in chirurgery; as bleeding, tooth-drawing, &c.
 They were formerly distinguished by badges:
 those of the long gown bore a case of instruments;
 the barber, a bason. The surgeons and barbers
 of Edinburgh were formerly united in one incor-
 poration, but were disjoined about 1720. See
 BARBERS, and SURGERY.

S U R G E R Y.

SURGERY, *chirurgia*, χειρ, manus, εργον, opus,
 embraces all those diseases which affect the solid
 parts of the human body, and which can in any
 way be relieved by a manual operation. In this
 paper we present the reader with, I. A concise
 history of this art; II. With a detail of those
 diseases, according to a classification prefixed.

PART I.

HISTORY.

The history of this now noble and important
 science, presents nothing calculated to awaken a
 very strong interest in its earlier records. In
 the pristine ages, when men led unvitiated lives,
 diseases were few, and considered, when they
 did occur, to be inflicted by the gods as a
 punishment for real or imaginary crimes. This
 supposition must have existed at the time of the
 Trojan war; for Homer describes the disorders
 among the Greeks, arising probably from the
 heat of the sun on the Trojan marshes, as destroy-
 ing arrows, hurled by Apollo in his anger,
 thus:—

Ουρῆας μὲν πρῶτον ἐπὶώχετο, καὶ κίνας ἀργεῖς.
 Ἀὐτὰρ ἐπειτ' αὐτοῖσι βέλους ἐχευενκες εἰμυίαι.
 Βαλλ' αἰεὶ δὲ πυραὶ νεκρῶν καιόντο Ξαμίαι.
 Ἐννημιῶν μὲν ἀνα στρατὸν ὤχετο κίλα θεῖοιο.

On mules and dogs the infection first began,
 At last the vengeful arrows fixed in man;
 For nine long nights through all the dusky air
 The pyres, thick flaming, shot a dusky glare.

These diseases, then, were to be removed only by
 prayer and supplication, and the cure effected
 through the medium of the priests. But as
 wounds, &c., were always liable to happen to
 men constantly engaged in warfare (which is to
 be expected in all imperfectly civilised societies),
 so men were naturally liable, through a desire of
 mitigating their companions' sufferings, to seek
 for and employ suitable remedies. The occupa-
 tion of attending to the wounds of their fellow-
 soldiers was thus reckoned honorable—and even
 kings did not disdain to practise it. Thus Homer
 extols several of his heroes not more for their
 valor than their knowledge of the healing art:
 such were Chiron, Machaon, and Podalirius:

and we may estimate the value set upon such men, by the eager desire of his companions to save Machaon when he had fallen in the battle wounded by an arrow. It was not until mankind had become settled in cities, and devoted their hours to the study of science, that medicine was considered as a legitimate object of enquiry, associated with the other branches of philosophy. It is not surprising therefore that, under these circumstances, the science of surgery should not have advanced: as its true basis must ever be found in anatomical knowledge. Pythagoras, Empedocles, and Democritus, were writers on medicine and surgery who only studied it in their closets; and it was not till the time of Hippocrates that diseases were made a separate study. This great man, being in affluent circumstances, gave his whole time to the study of medicine; not in the vague manner that his predecessors had done, but by actual observation and practice; by which he was enabled to write such a clear and definite account of diseases (but more especially acute ones) that moderns still express their admiration of it. He also treated of several surgical subjects with considerable success; but, as it is doubtful whether this great master had ever an opportunity of actual dissection, except of animals, we must not be surprised that this branch did not keep pace with medicine. The surgical subjects on which he has written are, Fractures, Dislocations, Wounds of the Head, Ulcers, and Fistula. After Hippocrates, we have no existing works published till the beautiful one of Celsus, from which we merely learn the names of those who professed medicine; these were Diocles, Carystius, Praxagoras, Chrysippus, Herophilus, and Erasistratus, which last two began anatomical investigations under the auspices of Ptolemy Philopater, in whose reign the study of medicine was divided into dietetics, pharmaceuticals, and surgery. This last art, says Celsus, was practised in Egypt by Philoxenes, Gorgias and Sostratus, Heron and the two Apollonii, with Ammonius Alexandrinus, who was distinguished by the name of Lithotomos. These flourished shortly before the Christian era. Whilst at Rome the principal surgeon, just before the time of Celsus, was Meges, who operated for the stone, &c.; so that surgery must have attained some progress. Celsus lived in the reigns of Augustus Tiberius, and Caligula.

After this there is again a considerable deficiency in the annals of surgery till the writings of Galen, who was born at Pergamus in Asia Minor, from which he went to Rome, in the second century, under the emperor Severus. He, however, did not practise surgery alone, preferring the study of medicine. Making comments, however, on the surgery of Hippocrates, he opened the jugular veins, and performed arteriotomy at the temples, recommended leeches, scarifications, and cupping glasses, to draw blood, and also described with accuracy the different species of herniæ, and the different methods of using bandages. In the year 500 flourished Ætius, who described many things omitted by Celsus, particularly relating to operations, and the diseases of women. His works, however, were much eclipsed by Paulus Ægineta,

who flourished in 640, and wrote a treatise on surgery superior to all the ancients.

This science was now, in common with all others, doomed to a long oblivion by the overthrow of the Roman empire. The resuscitation of surgery happened about the year 900, when the Arabians discovered the writings of the ancients, and appropriated them to their own use, making great additions, which but disgraced the original. Such are the compilations of Rhazes, Haly-Abbas, Albucasis, and Avicenna. Medicine, however, owes more to these men than surgery; for by their agency many new remedies were introduced from the east. From the eleventh century till the sixteenth, the practice of surgery was confined to ignorant priests, or still more unlearned barbers and farriers, with occasionally a quack strolling over Europe and imposing on the credulity of the superstitious by his magical rites. In the sixteenth century a new era sprung up. Fabricius al Aquapendente published his treatise on surgery, which drew from the illustrious Boerhaave the following compliment:—*Ille superavit omnis; et Nemo, illi; hanc dispartat gloriam; omnibus patius quam hocce, carere possumus.* And now anatomy, under the celebrated Vesalius, began to shed her influence over the cultivation of our art, giving rise to the father of modern surgery, Ambrose Paré, the first of the French surgeons. Educated in the Hotel Dieu, he was appointed body-surgeon to four of the French kings successively, Henry II., Francis II., Charles IX., and Henry III. These he followed to the field, and was held in such estimation by the soldiers, that it is said his presence in a besieged town was sufficient to reanimate the drooping defenders. He was one of the very few protestants that escaped the odious massacre of St. Bartholomew, by the protection of the king himself. The works of Paré abound with interest, although disguised by the absurd matter introduced by those whom he employed to write them. But surgery owes an immortal obligation to him for the discovery and use of ligatures to restrain hæmorrhage. In this respect he was the first to break through the trammels of the ancients, who always employed the actual cautery, which of course rendered them fearful of performing operations. Beneficial as this discovery was, it met with most violent opposition from the physicians of the time, who were astonished that a surgeon should dare to publish any plan of treatment not found in the writings of the ancients; and accordingly we find the use of the ligature after his death declined. Next to Paré, in the order of illustrious surgeons, followed Petit, in the seventeenth century, who cultivated anatomical knowledge when a mere boy, and published his treatise on diseases of the bones when only a very young man. This remained the best work on this subject for nearly a hundred years: he also published several other works and treatises, and was justly considered an ornament to the French school. About his time also lived Le Dran, who wrote several able works, as did Gaungeot, Le Lat Sabatier, Levret, Desault, who has given the profession much useful information on fractures, &c., to whom may

be added La Motte, Goulard, Daniel, Poteau, and Frere Cosme the lithotomist. But the genius of surgery was not confined to France; Holland had its eminent men; foremost amongst whom stands Raw, the most distinguished lithotomist in Europe, but who had the cruelty and meanness not only to conceal his mode of operating, but deceive his professional spectators, who came from all parts of Europe, by which many lives are said to have been sacrificed. He even concealed his operation from his intimate friends and pupils, Heister and Albinus, whose merits effaced the stigma of Raw from Holland, as did the conduct of the illustrious Camper in the following century. And now we begin to trace the surgical art in England. Wiseman, surgeon to Charles II., was the father of English, as Paré was of French surgery; and in his time lived Harvey, the great discoverer of the circulation, which constituted in itself a host of discoveries. To these succeeded Chesseldeu, White, Douglas, the two Monroes, Sharp, Cowper, Warner, Alanson, and Percival Pott (who first gave surgical lectures at Bartholomew's Hospital in 1729) Hawkins, Smellie, and the two Hunters. It is to John Hunter that we owe our now successful treatment of aneurism. It was he who first pointed out the danger of operating on a diseased artery, too fully confirmed by experience, and showed how that might be obviated: it is to him in fact that surgery owes the greater part of her scientific reasonings. He was also the best operator in his day, having once removed a tumor from the side of the head and neck, as large, if not larger, than the head to which it

belonged; and at another time dissected out a tumor which one of our best operators had declared, too hastily, that none but a madman would meddle with. He was also equally remarkable for his investigations in comparative anatomy. France has also furnished her (almost) Hunter in the person of Bichat, who gave himself up to anatomy and physiology, and died lamenting that he could not finish his labors. But, within the last twenty or thirty years, most important improvements have certainly been made in almost every branch of surgery; and it must gratify every Englishman to find that his own countrymen have acted a very leading part in effecting such an object, especially in operations on arteries. Thus this country may claim the names of a sir E. Home, an Abernethy, a sir A. Cooper, Lawrence, Guthrie, &c. France may also boast of her baron Savrey, Dupuytren, Roux, &c.; and Italy of a Scarpa.

PART II.

DETAIL OF DISEASES.

INTRODUCTION.

As little has been done towards a methodical arrangement of those diseases which come within the defined limits of surgery, the following attempt at a classification must therefore be received with candor and allowance. The utility of a classification in the method of induction, by affording appropriate divisions for the allotment of facts and phenomena, has of late been too well understood to render it necessary for us to insist upon in this place.

CLASSIFICATION.

CLASS.—DISEASES AFFECTING THE SOLIDS.

ORDER I.—EVIDENTES, arising from manifest causes.

ORDER II.—OCCULTI, where the cause is not apparent.

ORDER I.—EVIDENTES (comprehends three genera).

<i>Genus 1.</i>	<i>Genus 2.</i>	<i>Genus 3.</i>
<p>VIOLENTES. From mechanical injury. <i>Species.</i> Wounds causing hemorrhage. Tetanus. Empysema.</p> <p>Contusions. Fractures. Dislocations. Rupture of tendon Achilles. Sprains. Injuries of head. Hernia.</p>	<p>VENENANTES. From the action of poisonous matters. <i>Species.</i> Syphilis. Gonorrhœa. Hydrophobia. Dissecting wounds.</p>	<p>LETHALES. From the application of matters tending immediately to the destruction of vitality. <i>Species.</i> Burns and scalds. Frostbites. Chilblains.</p>

ORDER II.—OCCULTI (having two genera).

Genus 1. **DIFFUSI.** Affecting the system at large.
Species.—Scrofula.
Hysteria.
Cancer.

Genus 2. LOCALES. Attacking particular parts.

This is the largest genus, and comprehends many species, being diseases of the

CHAPTER I.—OF INFLAMMATION.

Most surgical writers have concurred in commencing their subject with some account of the phenomena of inflammation: and with good reason; for most diseases that come within the province of a surgeon are either immediately dependent upon, or are intimately connected with it.

The word inflammation, from *inflammo*, to burn, or kindle, conveys its own definition, on account of the burning heat experienced by the patient in the part affected by it.

SECT. I.—ON THE SYMPTOMS AND TERMINATIONS OF INFLAMMATION.

When inflammation attacks any part, the symptoms which indicate its presence are redness, heat, pain, and tumor, together with interruption or derangement of any function which the part attacked may have to perform; and if it be violent, or of large extent, the constitution sympathizing with it remarkably, it produces a greater or less degree of fever. It is also frequently preceded by a cold shivering, particularly when it affects important parts. But it is obvious that many of these symptoms may at times be wanting, or rather that we cannot expect to find them. Thus, for instance, if the affection be of an internal part, we cannot expect that redness should be visible, nor can we generally detect any tumor in such cases.

These symptoms require a little separate consideration; and first the pain, as the least variable, presents itself to our notice. When any part is inflamed, we observe (if external) that the capillary vessels, which were too small previously to be able to receive red globules of blood, become distended so as now to admit them with facility, and at the same time the main artery near the affected part becomes enlarged in its calibre, so that a much greater quantity of

blood is admitted into an inflamed part than is natural. This will at once account for the swelling of the part, and also the pain which is evidently caused by the sudden stretching of the nerves. It is also probable that, having increased their vascularity, they may become more sensitive. It is difficult perhaps to explain exactly how the pain is produced; for as Mr. Samuel Cooper, in his excellent work called 'First Lines of the Practice of Surgery,' says, 'It is more easy to conceive than describe how any deviation from the natural state of parts must excite pain.' It is the unusual condition into which the nerves are thrown, which is to be regarded as the proximate cause. In chronic inflammation the graduality of the change allows the nerves to become adapted to it, and the degree of pain only amounts to a dull uneasy sensation; but in phlegm, or when the change is quick, the pain is considerable. The throbbing which accompanies the pain manifestly depends on the strong pulsation of the arteries. Pain then may be considered as a constant attendant on acute inflammation; but, when it is of a more chronic character, there may be either very little or (or as in some scrofulous tumors) none at all.

The *tumor* has been noticed to depend on the increased quantity of blood in the part, but it is also assisted by effusion of lymph into the cellular interstices; which takes place after inflammation has been established for a very short period. It is also probable that, in this state, absorption does not proceed so rapidly as in healthy parts.

The *redness*, when apparent, must also depend upon the inflamed vessels carrying red particles, which they could not receive in their natural state. This is particularly manifest in inflammations of the eye.

Increased heat.—This is in many cases an illusive symptom; for it is sometimes felt in internal

as well as in external parts. Its existence in external parts may be easily accounted for. The blood near the heart, and in internal surfaces, is commonly at nearly 100° of Fahrenheit, whilst the temperature of the surface of the body is materially lower, on account of the constant evaporation kept up by both the sensible and insensible perspiration; but, when any part becomes inflamed, it admits a much greater quantity of blood, and this causes an unusual sensation of heat upon the nerves accustomed to a lower temperature. It is, however, not so easy to explain the feeling of heat in internal inflammations; that such increase above the natural temperature is not real, but only imaginary, has been proved by several experiments of Mr. John Hunter, who excited inflammation in the chest of a dog, and in the abdomen, rectum, and vagina of an ass, without being able to discover any obvious rise of temperature. It may, however, be noticed that in some diseases the whole mass of blood is augmented in temperature, sometimes rising as high as 106° or 107° Fahrenheit.

There is yet one more symptom of the presence of inflammation, which, being a secondary one, has not yet been noticed. This is the buffy coat found on the blood which has been abstracted from the patient when affected by this complaint. This appearance has been well accounted for by John Hunter, in his excellent Treatise on the Blood:—He says, ‘The blood, when taken out of the living vessels, spontaneously separates into two distinct parts, the serum and the crassamentum. The last is a compound substance, consisting chiefly of coagulating lymph, and red globules, the most heavy ingredients in the blood. Blood, taken away from persons affected with inflammation, is longer in coagulating, and coagulates more firmly, than in other instances. Hence the red globules, not being so soon entangled in the lymph, descend, by their gravity, more deeply from its surface, which, being more or less divested of the red coloring matter, is, from its appearance, termed the buffy coat, or inflammatory crust. The firmer and more compact coagulation of the lymph compresses out an unusual quantity of serum from it, and the surface of the sily blood is often formed into a hollow, the edges being drawn inward.’

Having thus briefly described the symptoms of inflammation, the terminations of it are next to be considered. These are various, as 1. Resolution; 2. Effusion; 3. Ulceration; 4. Mortification; or it may pass on imperceptibly into a chronic state.

1. *Resolution*.—This is the most favorable termination, consisting of that state of the body in which nature is able to overcome the morbid action, and restore her own regularity of function; and this is, on the whole, the most common termination. It is effected in the following manner:—‘The pain becomes less, the swelling subsides, the fever, and every other symptom, gradually abate, till at last the part is wholly restored to its natural size and color. There is no formation of pus, nor any permanent injury of structure.’

2. *Effusion*.—This may be of various matters, as i. Serum. This is peculiarly liable to take

place from serous membranes; as, for instance, a man receives a blow on the testicle which becomes slightly tender, and is followed by an effusion between the tunica vaginalis, propria, and reflexa testis. This forms what is commonly called hydrocele, and is in fact a serous effusion; or a person is struck on some part where the cellular texture is very loose; as, for instance, the eye-lids, a slight inflammation follows, which is succeeded by a serous effusion into the cells. In internal cavities this is frequent, as the head, chest, and abdomen. ii. Fibrine or lymph. This generally occurs where the inflammation is very severe, and is in fact the solid part of the blood. This happens indiscriminately in all structures, as is seen in inflammations of veins or arteries which have been tied or cut across, or in all common incised wounds, causing adhesion by the first intension. It may also take place in solid or glandular bodies, causing permanent induration, as in affections of the testis or epididymis, which frequently remain during the patient's life. It is, however, less frequently met with in mucous surfaces, which seems a kind provision of nature, for as these last are canals, the stoppage of them by adhesion would be fatal. iii. Purulent effusion. This may take place in any part or structure of the body, and is often a very unfavorable termination. This is generally called suppuration, which when it happens in circumscribed cavities is generally fatal, as in the head, chest, or abdomen; it may, however, occur in parts contained within these cavities, and not necessarily terminate fatally. Thus an abscess may form in the liver which may burst and discharge its contents externally or into the biliary ducts, and eventually heal. This effused fluid pus, resembles cream in its consistence, is heavier than water, and is composed of particles nearly similar to the fibrine of the blood floating in a fluid. ‘The fluid part of pus resembles serum; and, like it, is coagulable by heat; but it cannot, like milk, be coagulated by the gastric juice of animals. Healthy pus has little smell, is void of acrimony, and is of the consistence of cream, its globules are abundant, and of a lightish color. When pure, it does not readily putrify; but this quality is lost when there are extraneous additions blended with the matter. In specific diseases, cases of caries, &c., the matter is often mixed with blood, coagulating lymph, &c., and then it has more tendency to putrify and become offensive. Pus always partakes of the nature of the sore which produces it. To the surface secreting it, pus is quite unirritating, though it may greatly irritate any other. Hence, it is useless to wipe matter so completely from the surface of granulations as some are wont to do; but it is highly proper to keep the surrounding skin free from it.

‘Secretions of another kind sometimes have a resemblance to pus. The following circumstances form a line of distinction. Pus sinks in water, mucus floats; pus communicates to water a uniformly troubled white color, mucus gives the appearance of stringy portions floating in it; mucus is more readily dissolved by sulphuric acid than pus. If water be added to such solutions, the pus is precipitated to the bottom,

while the mucus, instead of being completely precipitated, forms swimming flakes. A solution of caustic alkali dissolves both pus and mucus; but, when water is added, the pus becomes separated, but not the mucus.'

When an effusion of pus takes place in a solid part, or in cellular texture, it becomes surrounded by a membranous bag or cyst, partly by condensation of surrounding texture, and partly by effusion of lymph, and forms what is commonly called an abscess, derived from *abscedo*, to go away, because the ancients believed it to be formed by the dissolution or departure of the solids from their natural condition. But that pus may be formed without any dissolution of the solids, was noticed first by Dr. Hunter in cases of *empyema* or collections of pus in the chest, and afterwards by John Hunter, in his *Treatise on Gonorrhœa*, wherein it is demonstrated to be secreted from the mucous surface of the urethra for a long time, without any breach of the surface in either case. 'The modern doctrine of suppuration is, that the pus is separated from the blood by the inexplicable operation of the secreting arteries, just as ordinary secretion takes place, and that the peculiar mode of action in the arteries is the reason why pus should be separated from the circulation, rather than coagulating lymph, mucus, &c. &c. It is further believed that the solids never suffer any dissolution, so as to enter into the composition of pus, and that the deficiency frequently apparent in them, arises from absorption. The arteries, in producing pus, a fluid so dissimilar from blood, and of which, at least, it must be considered a new combination, seem to assume all the power of glandular secretion.'

The symptoms of suppuration are, after a long continued inflammation, without signs of resolution, the patient has a remission of the fever (if any were formerly present) and pain; the redness also subsides round the part, but becomes more dull upon it, presenting a yellowish or whitish appearance in the middle. He has frequent shiverings (these are particularly marked in suppurations after injuries of the head), and the humor grows larger; and, if superficial, has a conical eminence, upon touching which a fluctuation is apparent. If, however, it be deeply seated, there is tenderness on pressure, and a considerable œdema of the limb; the pulse becomes soft, and in large suppurations hectic fever supervenes. The treatment of abscesses in general will be found in the treatment of inflammation and its consequences.

3. *Ulceration* is a preternatural increase in the action of the absorbents beyond the proportional power of deposition from the arteries; causing a rough surface to be formed, which, in healthy ulcers, is covered with pus, not adherent to its surface, and the roughness is caused by small projections of a conical form called granulations. These are very common, sequels of inflammation, particularly if any thing have deprived the part affected of a portion of its vitality. Thus most severe bruises, where the nerves have been compressed, are liable to end in ulceration; and it is a remark of Mr. Brodie's that all extraneous morbid growths, as schirrus or other

tumors, are very liable to ulcerate. The parts, too, nearer the heart are less liable than those remote. They are also of very frequent occurrence after fevers in the mucous follicles of the small intestines. Ulcers in parts of much vitality would naturally heal were it not for some foreign cause. Their mode of healing is by the granulations rising to a level with the surrounding skin, from the edges of which new skin gradually forms and spreads over the ulcer; or else, in large ulcers, a spot of new skin forms in the middle, from which portions shoot like rays.

Sir A. Cooper notices that it is a curious law, with respect to the ulcerative process, that it has a tendency to the nearest external surface of the body. This is a law which is attended with the most salutary effects; for, if it were otherwise, the body would very frequently be destroyed by the ulcerative process. In consequence of this tendency, matter formed at a depth in the body finds its way through the integuments, instead of proceeding through the more important parts. Many examples may be given of this law. One of the most remarkable is this:—Matter forms not unfrequently behind the sternum close to the pleura and pericardium, which membranes are extremely thin—not so thick as paper. From the proximity of these membranes it might be expected that the matter would generally open into the pleura, and, by discharging itself into the cavity of the chest, destroy life. Instead of this, however, the pleura undergo no other alteration than that of becoming thick, and, while they are acquiring this addition of substance, the process of absorption is going on in the inner part of the sternum, an aperture is formed through it, and the matter makes its way through the bone and integuments rather than through the pleura and pericardium. The same circumstance takes place with respect to the peritoneum. If matter be formed in the abdominal muscles, the peritoneum is very rarely absorbed to admit the matter into the cavity of the abdomen, but the matter makes its way through the integuments, and finds an outlet on the surface of the body.

Ulcers have been divided by Sir Everard Home, in his excellent treatise, into six varieties, which are, 1. Ulcers in parts which have sufficient strength to carry on the actions necessary for their recovery. 2. Ulcers in parts which are too weak for that purpose. 3. Ulcers in parts whose actions are too violent to form healthy granulations, whether this arises from the state of the parts, or of the constitution. 4. Ulcers in parts whose actions are too indolent, whether this arises from the state of the parts, or of the constitution. 5. Ulcers in parts which have acquired some specific action, either from a diseased state of the parts, or of the constitution. 6. Ulcers in parts which are prevented from healing by a varicose state of the superficial veins of the upper part of the limb.

i. Simple or healthy ulcers.—Sir E. Home remarks that, in this species of ulcer, the pus is of a white color, thick consistence, and readily separates from the surface of the sore, and when diluted, and examined in a microscope, is found to be made up of small globules, swimming in a transparent fluid. The granulations are small

florid, and pointed at the top. As soon as they have risen to the level of the surrounding skin, those next to the old skin become smooth, and are covered with a thin semi-transparent film, which afterwards becomes opaque, and forms cuticle.

In the treatment of this kind of ulcer, it is only necessary to keep the surface clean, and prevent the natural processes from being interrupted. Sir E. Home observes that this is in general best done by the application of dry lint, for the purpose of absorbing and retaining the matter, which serves as a soft covering for the granulations, and by putting over the lint a pledget of any simple ointment, in order to hinder the matter from evaporating, by which means the dressings will not become adherent, and may be easily taken off as often as requisite. Although healthy ulcers require no medicated application to be made to them, the dressings must be such as do not disagree with the granulations or surrounding skin. A roller is also often useful to support the skin and muscles, which are sometimes relaxed from the want of natural exercise of the part. When the sore, however, does not secrete enough in twenty-four hours to moisten the lint, a little simple ointment may be used, or it may be dressed only once in two days.

ii. Weak or fungous ulcers.—The granulations of these sores are larger, more round on their external surface, and of a less compact texture, than those formed on ulcers in healthy parts. Sir E. Home has also noticed their semi-transparent appearance. When they have filled up the cavity of an ulcer to a level with the surface of the body, they do not readily form skin, but, rising up in a still higher manner, often lose altogether the power of producing new cutis. When the parts are still weaker, the granulations sometimes continue gradually to fill up the hollow of the ulcer, and then, all on a sudden, are suddenly absorbed, so as to leave the sore as deep as it was before. Ulcers may be weak from the first, or become so in the progress of the case. Even granulations of the most healthy kind, if they are not skinned over in a certain time, gradually lose their primitive strength.

These ulcers appear in persons debilitated, either mentally or bodily. In the *treatment*, therefore, of this kind of ulcer, tonics are to be exhibited, particularly bark and steel, and every thing which disagrees with the constitution is to be avoided. Wine and cordial medicines are also usually prescribed. Porter, however, is deemed better than wine for working people. The local treatment is to prevent the granulations rising too high. This, says Sir E. Home, is better accomplished by keeping them down by strong stimuli than by allowing them to rise and then destroying them. Pressure also is very useful, either by bandage or a piece of sheet lead, as stimuli. A weak solution of argemum nitratum may be used, or powdered rhubarb, which, if too exciting, may be mixed with a fourth part of powdered opium. The best ointments are, the ung. Lyd. nitri. or ung. nitrico. oxyd. each diluted with five parts of hog's-lard.

iii. Irritable ulcers, when well marked, have

these symptoms:—The margin of the surrounding skin being jagged, and terminating in an edge, which is sharp and undetermined. The bottom of the ulcers being made up of concavities of different sizes. There being no distinct appearance of granulations, but, a whitish spongy substance, covered with a thin ichorous discharge. Every thing that touches the surface gives pain, and very commonly makes it bleed. The discharge is altered from common pus to a thin fluid, in proportion to the degree of irritability communicated to the sore by constitutional causes.

When the above-mentioned signs of an irritable ulcer are not present, we must form a judgment of the nature of the sore from listening to the history of the case, the effects of various applications, &c. When this kind of information cannot be obtained, Sir E. Home recommends the treatment to begin on the supposition of the ulcer being of an irritable nature. Irritable sores are very often situated over the lower end of the tibia, or anterior edge of the tibia.

Treatment.—All applications should be sedative. Thus steaming the part or fomenting with decoct. papav. or applying lint dipped in a solution of hemlock, or opium, will be found beneficial. Emollient poultices may be used as a continued application. But, as the patient cannot always bear their weight, it should be contrived that the part may rest on the poultice instead of the poultice on it. They are, however, to be left off, if they relax the ulcer too much, causing flabby, large granulations with a gaping wound. Powdered charcoal has been found useful, as has cold cream when the patient could not bear heat.

iv. Indolent ulcers.—The indolent ulcer forms in its appearance a complete contrast to the irritable one. The edges of the surrounding skin are thick, prominent, smooth, and rounded. The surface of the granulations is smooth and glossy. The pus, instead of being of a perfect kind, is thin and watery, being composed of a mixture of pus and coagulating lymph. The lymph consists of flakes, which cannot be easily separated from the surface of the sore. The bottom of the ulcer forms quite a level, or nearly so, and, as Sir E. Home very accurately remarks, the general aspect conveys an idea that a portion of the skin and parts underneath has been for some time removed, without the exposed surface having begun any new action to fill up the cavity. When, however, the indolence of the ulcer is not so strongly marked, the sore does not correspond to the preceding description, but resembles in appearance the ulcer which possesses an inferior degree of irritability, and can only be discriminated from it by receiving no benefit from soothing applications. These are the ulcers that most commonly occur in old persons, and so we find a great number in every hospital.

Treatment.—Solutions of lunar caustic; touching the surface of the ulcer with the caustic itself; diluted nitrous acid; the unguent. hydrarg. nitrat.; and the unguent. hydrarg. nitrat. rubr.; and supporting the sore and the neighbouring skin and muscles with a roller; are the best means which were used for healing common indolent ulcers, before Mr. Baynton laid before the

public his very successful method. This gentleman's practice consists in applying strips of adhesive plaster round the limb, so as to cover the sore, and, at least, one inch of the parts both above and below the ulcer. The strips of plaster are to be two or three inches broad, and long enough to surround the limb, and leave an end about four inches long.

The middle of the strip, so prepared, is to be applied to the sound part of the limb, opposite the inferior part of the ulcer, so that the lower edge of the plaster may be placed about an inch below the edge of the sore; and the ends are then to be drawn over the ulcer with as much gradual extension as the patient can well bear. As many strips are to be applied in this manner as will cover the whole surface of the sore, and one inch of the limb below and above it. Soft compresses are to be laid over the part, and the limb is to be rolled, from the toes to the knee, with calico bandages. The affected parts are then to be kept moist with cold, spring water, which enables the surgeon to remove the strips of plaster without hurting the patient, and, at the same time, keeps off inflammation.

v. Ulcers with specific action.—These are very various; as the scrofulous, venereal, cancerous, &c., which will be treated of under these separate articles. A few, however, may be mentioned here. 1. An ulcer noticed by Sir E. Home, particularly in servants who have led indolent lives, occurs on the instep and foot, has very thick edges, and is attended with a diseased state of the surrounding skin, so as to bear some resemblance to elephantiasis; these are to be cured by mercurial fumigations and applications. 2. Ulcers which appear on the ankle or knee with swelling of the joints.—These are generally suspected to be scrofulous, but they are more painful than strumous ulcers commonly are. These are best managed by applications of hemlock. 3. There is a kind of ulcer which does not extend more deeply than the cutis, but spreads in all directions. The specific morbid action does not continue in the parts, which have ulcerated, but only affects the edge of the skin, where the ulcer is increasing; for the surface first affected heals, while the parts beyond are in a state of ulceration. For such ulcers, of which there are several varieties, a solution of the *argemum nitratum* is the best application.

The last specific ulcer which I shall here notice is the fungated one. It is seen on the calf of the leg and sole of the foot, shooting out a fungus from the surface. The new formed substance is extremely broad, and narrow at its root; it is tender, and bleeds from very slight causes. The disease, in its origin, somewhat resembles a scrofulous affection of the metatarsal bones, until the skin ulcerates and the fungus protrudes. One species of this ulcer contaminates the lymphatic glands in the course of absorption; another kind does not do so. The first case cannot be cured by the internal and external use of arsenic; the second may.

vi. Varicose ulcers.—These are generally situated on the inside of the leg, having somewhat the appearance of indolent ulcers, but may be known, as the name implies, by a varicose state of the saphena vein.

Treatment.—A horizontal posture is absolutely necessary to take off the weight of the superincumbent column of blood; apply *lotio nigra* to the wound, oiled silk or sheet lead over this, and then bandage the limb tightly from the foot upwards. Sir A. Cooper recommends bleeding from the affected veins. It is obvious that the varicose ulcer must be alleviated by any thing that will benefit the condition of the varicose veins themselves—to the article on which, this consideration must be referred.

vii. There are some ulcers which may be hindered from healing by mechanical impediment, as constant motion. Of this sort are those called fistula, which will be separately treated of; also abscesses in the lungs, or other moveable viscera; others by some irritating cause, as ulcers of the toes under the nail. These are very troublesome on account of the nail growing into the ulcer, from which a little fungus sprouts.

Treatment.—Sir A. Cooper notices that there are two modes of treating these ulcers; either the application of a blister; or introducing a piece of lint under the nail; the former brings away the cuticle and sometimes the nail along with it; the latter, however, is more lenient, and a better remedy. Pare down the nail as thin as you can, without producing bleeding; then raise it a little, and introduce a small piece of lint: in this way the irritating cause may generally be removed; but sometimes it happens that the sore is so exceedingly irritable that even lint cannot be lodged on its surface without producing increase of inflammation and pain; in such cases, I would recommend slitting up the nail with a pair of scissors, on that side where the disease exists, and then, with a pair of forceps, turn back and completely remove the divided portion. The part should be poulticed after the operation.

There is another not uncommon ulcer, which has not yet been noticed; this is the gangrenous or phagedenic ulcer. In ulcers of this kind, the surface is perfectly free from any discharge; the surrounding edges of a livid appearance; with small vesicles or blistered spots on them; and the patient suffers much from irritative fever.

In the *treatment* of these cases you must adopt constitutional as well as local remedies: the recumbent posture must first be enjoined, as it is essentially necessary to promote the separation of the dead parts; a generous diet allowed; stimulating medicines administered; and moderate stimulating applications, to promote a slightly increased action on the part; sometimes, however, when the action is excessive, you must, on the contrary, sooth the part, and lessen the stimulating nature of your constitutional treatment. The most approved constitutional treatment in these ulcers is rest and generous diet; port wine should also be allowed, and spirits may be given to those who have been in the habits of using them: by brandy and opium I have seen these wounds cured; in fact, they are our sheet anchors in the treatment of gangrenous ulcers. The best medicine to be administered is opium and ammonia; twenty drops of the tincture of opium, three times a day, with ten grains of the ammonia, in an ounce and a

half of camphor nixture, and one drachm of compound tincture of cardamoms.

When there is debility of the part, a slight stimulus should be employed; but when there is excessive action it is to be avoided. The best application for producing a slight stimulus, and checking gangrene of the part, is the nitric acid; there is none equal to this; fifty drops of it to a quart of distilled water is the average quantity; but this, however, may be increased or diminished, just as it may give pain to the part.

We come now to consider the next termination of inflammation. This is

4. *Gangrene* or *Mortification* (from *γρωα* to feed upon, because it consumes the living flesh). This, the worst, is happily the least frequent sequel of inflammation, and occurs only when the affection has been of the most severe character; and seems to be produced by the sudden failing of nervous energy in the part attacked, in consequence of its being no longer able to continue that high state of excitement which such severely increased action demanded: as we may imagine a bow to be bent till it snaps asunder. When this happens, there ensues a loss of life to a greater or less extent in the part affected. There frequently, however, occurs a gangrene in parts which have not been previously subjected to inflammation; but which, for some reason or other, are endued with less vitality. This has been called idiopathic or dry gangrene, in contradistinction to the other, which is the humid or acute. There are besides cases of mortification, preceded by inflammation, which do not arise wholly from that as a cause, but combined with a deficiency of vitality; of this nature are carbuncle, and the slough formed in the small-pox pustule, &c.

Symptoms of gangrene.—The symptoms of mortification from inflammation take place variously, yet generally, as follows. The pain and sympathetic fever suddenly diminish, the part affected becomes soft and of a livid color, losing at the same time more or less of its natural warmth and sensibility. In some places the cuticle is detached; while, in other situations, vesicles arise, filled with a clear or turbid fluid. On touching the part, there is a crepitus perceptible, owing to the generation of air, from the decomposition of the cellular substance. As this state of things proceeds, the parts become quite black, flaccid, easily lacerable, destitute of heat, motion, and sensation. They are now said to be in a state of sphacelus or mortification. Mr. Thompson observes, in his Lectures on Inflammation, that ‘the part of the body which becomes affected with gangrene does not immediately lose its sensibility; for the pain, on the contrary, is often very much aggravated by the approach of this state. The blood also still continues to circulate, at least in the larger vessels of the part, but perhaps with less force; and, from the resistance which it meets with in passing through the capillaries, in less quantity than formerly. The serous effusion into the cellular membrane continuing to increase, and the action of the absorbent and sanguiferous vessels to diminish, the part becomes at length incapable of being restored to its former office in the animal

economy. It is therefore in its earlier stages only that gangrene is to be considered as an affection admitting of cure; for there are limits beyond which, if it pass, recovery becomes impossible. These limits it may not in every instance be easy to define; but they form the boundaries between incipient gangrene and the ultimate termination of that state in sphacelus.’ When sphacelus, however, has taken place, it always has a tendency to spread and deprive the neighbouring textures of their vitality, and it stops only when it encounters a part which has vital energy enough to resist it. It is then that nature draws a line of separation between the living and dead matters, which last, if left to themselves, are gradually thrown off, leaving for the most part a healthy ulcer exposed.

The separation of mortified parts or sloughs would be attended with great danger from hæmorrhage, where it not kindly provided by nature that the arteries leading to a part thus affected, having no longer any circulation to carry on, become obliterated by lymph, so that the patient is secured from this terrifying addition to his sufferings.

The constitutional symptoms that occur in acute gangrene are a high degree of irritative fever, gradually assuming the form of typhus, with a quick, small, and thready pulse, generally intermitting, and often accompanied by delirium of the low or muttering character, and vomiting, together with a very uniform and important symptom, hiccough. Frequent cold sweats supervene, and the patient’s countenance assumes a wild cadaverous look.

Mortifications not following acute inflammation.—These may occur from various causes; as 1. A simple diminution of vitality, which takes place in the sloughing of extraneous growths. 2. Pressure on the veins of any part obstructing the return of blood. In this case the blood-vessels become turgid, and the part swells, and becomes livid and very painful. Vesicles soon arise, and, at length, the part becomes soft, œdematous, emphysematous, cold, black, insensible, and fetid. A strangulated hernia affords an instance of such mortification. 3. Impediment to the flow of arterial blood to the supply of a part. This produces first softness and boldness of the part, which soon becomes shrivelled, black, and lifeless—parts enclosed in very tight ligatures are examples of this. 4. Pressure obstructing the general circulation. Surgeons have frequent occasion to see melancholy examples of this kind of mortification, particularly in cases of fractures, paralysis from disease of the vertebra, &c. The mischief most readily occurs where the bones have the least flesh upon them, and consequently where all external pressure has the most effect; as, for instance, about the os sacrum, or ilium, spines of the scapula, &c. The disordered part always first becomes soft, livid, red at the circumference, and œdematous, afterwards losing its sensibility, and acquiring a black appearance: at length it is converted into a foul sloughing ulcer. 5. Violent concussions or contusions. 6. Extremes of heat applied suddenly. 7. Extremes of cold applied suddenly: all these three last occasion immediate loss of vitality. 8. Long

continued application of moderate cold or heat. 9. Ossification of arteries in old persons, as proved by Mr. Hodgson, though Pott has denied this. 10. A peculiar sort of mortification, beginning at the extremity of one or more of the small toes, and passing on to the foot and ankle, and sometimes a part of the leg, quite unprecedented by any inflammation. In some few instances it makes its appearance with little or no pain; but commonly the patient feels great uneasiness through the whole foot and ankle-joint, particularly in the night time, even before the parts show any marks of distemper, or while there is only a small discolored spot on the end of one of the little toes. From this spot the cuticle is always detached, and the skin underneath is of a dark red color. Sometimes it is slow in spreading from toe to toe. At other times its progress is rapid and horribly painful. It is most frequent in males, and is more often met with in the rich and voluptuous than in the laboring poor. It frequently happens to persons advanced in life; but it is by no means peculiar to old age. It is said to happen often in persons subject to gouty pains in the feet, without having regular paroxysms of the disorder. Few mortifications proceed so slowly as that now described; it spreads, however, more quickly when it invades fleshy parts. 11. Gangrene of an epidemic character. This is commonly called hospital gangrene, and is to be noticed where a great many wounded people are crowded together in a confined space. This first shows itself locally, says Mr. Thompson, by 'a more or less acute pain, and a viscid whitish exudation on the surface of the granulations, which lose their vermilion color, and present at several points spots of a grayish or dirty-white hue, resembling venereal ulcers, or aphthæ. These ulcerated points, thus engrafted (as it were) upon the original ulcer, soon spread and join together, so as to give to the whole surface of the solution of continuity a gray ash-color. The surface also becomes more or less indurated, and sometimes bleeds. A red, purplish, œdematous circle, of a greater or less extent, is next formed in the surrounding skin. Sometimes, when the patient is of good habit, the causes of infection less active, and the constitution sufficiently strong, the disorder has now a stop put to it. Indeed, as we have already remarked, it may not even extend to the whole surface of the ulcer. But most frequently its progress is extremely rapid, and occasionally quite terrifying. The edges of the wound, or ulcer, become hardened and everted, the granulations are large and tumid, being, according to Boyer, swelled up with a considerable quantity of gas. They are afterwards detached in the form of soft reddish sloughs, which, says Boyer, very much resemble the substance of the fetal brain when in a putrid state. From day to day, until nature alone, or aided by art, puts limits to the disorder, it invades new parts both in breadth and depth, so that its ravages extend to aponeuroses, muscles, blood-vessels, nerves, tendons, the periosteum, and even the bones themselves. Inflamed absorbent vessels are sometimes seen extending from the surfaces affected with hospital gangrene, to the contiguous or commu-

nicating, cervical, inguinal, or axillary glands.

Artery seems to be the texture which resists most powerfully the destructive action of hospital gangrene, as well as of most other species of mortification. When adhesive inflammation does not occur, hemorrhage is liable to take place, and, in some instances, to prove fatal. Even in cases in which distinct hemorrhage does not occur, a thin, fetid, bloody sanies is often discharged, and the pus, which is secreted during the separation of the sloughs, is frequently reddened by an admixture of blood.

These are the principal causes of gangrene; the treatment will be considered when we come to speak of the treatment of inflammation in general, and its consequences.

The last termination of inflammation may be said to be its passing into a chronic form. This, however, differs little from the acute, except in the mitigated violence of the symptoms. But chronic inflammation may happen, as it very commonly does, without any previous acute attack. It is to be observed that it is this which causes or accompanies most surgical complaints.

There has as yet been noticed only one sort of inflammation, viz. common or phlegmonæus; but besides this there are various specific inflammations, either produced constitutionally, as rheumatism, gout, scrofula, schirrus; or by application of some poison, as syphilis, &c.; but of these some come within the province of the physician, others will be mentioned afterwards.

SECT. II.—OF THE CAUSES OF INFLAMMATION.

These have been divided by most writers into remote and proximate. By the remote cause is meant both the indirectly predisposing and the directly exciting cause; and, by proximate is meant, in fact, an illustration of the *modus operandi* of inflammation.

1. *Remote*, considered under its two divisions: i. *Predisposing*. This, as the term implies, denotes all those necessary causes which render a person more liable to inflammation at one time than at another; as, for instance, a state of debility produced by any means whatever, as excessive fatigue of body or mind, want of proper nourishment, &c. &c. That some predisposing cause is necessary to produce this malady, is obvious from this, that many persons may have been equally subjected to an exciting cause, but of these a few only are attacked. ii. *Exciting causes*. All substances applied to the body, tending to injure the vitality of the parts that they touch. This includes chemical agents, especially stimulants, as cantharides, heat, acids, alkalies, metallic oxides, salts, and acrid vapors, as many of the gases. But the most curious though common agent is cold. This may be applied to one part and produce inflammation in another, as is seen in the production of diseases of the chest when cold is applied to the feet. It however often has a local effect, as is seen in frost-bitten parts, chilblains, or inflammations of the fauces and nostrils, from inhaling cold air. Touching a piece of metal previously cooled to a very low degree will produce a blister, and a sensation similar to that of burning; so that cold, though not considered by many

as a direct exciter of inflammation, may, however, very fairly be classed with the other causes, all of which excite it by the violent effort of nature in the threatened part, to rid herself of the noxious matter.

2. *Proximate cause.*—This has been a favorite topic of controversy amongst medical philosophers for several ages. Boerhaave supposed it to depend upon a too great viscosity of the blood, which clogged up the vessels: he also imagined that, in consequence of the perspiration being stopped, the smaller vessels were distended with it; so that the thick red globules found their way into these capillaries, forming an error loci. This created resistance to the circulation, causing heat, pain, and redness, by the accumulation of blood behind. Mr. Burns says, ‘The viscosity of the blood cannot be admitted as the proximate cause of inflammation; because we have no proof that this state ever exists; or, granting that it did, it would not explain the phenomena. Were a viscosity to occur, it would exist in the whole mass of blood, would affect every part of the body alike, and could not be supposed to produce only a local disorder. How also could such a lensor be produced by causes which bring on inflammation suddenly, without there being time for changes of the fluids to take place?’

‘With regard to the doctrine of error loci, or of red globules going into vessels which did not formerly transmit them, the fact must be admitted, at the same time that the conclusion is denied. When the eye becomes inflamed, the tunica conjunctiva is seen with its vessels full of red blood, which in health is not the case; but this redness never appears until the inflammation has commenced, and must therefore be considered as an effect, not a cause. Nor can this error loci occasion any obstruction in these vessels; for if they be divided the blood flows freely, which shows that they are large enough to allow an easy circulation.’ Dr. Cullen believed that it is produced by a spasm of the extreme vessels, with an increased action in the course of them. The inconsistencies in Cullen’s theory are very glaring. The congestion or accumulation of blood, which is only an effect or consequence of inflammation, is set down as the cause of the spasm of the vessels, to which spasmodic constrictions, Cullen, strangely enough, assigns the name of proximate cause. The spasmodic contraction of the extremities of the vessels, instead of propelling the accumulated quantity of blood, would render the passage of the blood from the arterial into the venous system still more difficult. Mr. Hunter believed that inflammation is to be considered only as a disturbed state of parts, which require a new but salutary mode of action to restore them to that state wherein a natural mode of action alone is necessary.

It used to be generally considered that the pulsation of arteries causing throbbing was in consequence of the contractile action of such vessels. But Mr. Brodie has proved in recent experiments that pulsation depends upon the stroke of the heart in a great measure, if not entirely. In one experiment, to prove this, he laid bare the carotid of an ass; and, having divided it, insert-

ed a glass tube into the lower portion, to the end of which was attached a silken tube, and he found that, when he allowed the blood to flow, the silken tube pulsed as strongly as an artery. To refute the old doctrine of spasm, or obstruction in the capillaries, Dr. Wilson, in company with Mr. Boraston, instituted some experiments. He found that in an inflamed web of a frog’s foot the capillaries, particularly the anastomosing vessels, were inordinately distended, so as to admit red globules, which they could not do previously; but at the same time the rapidity of circulation was diminished in proportion. These experiments have been corroborated by Mr. Brodie, who supposes that these vessels are dilated beyond their powers of contraction, so that they become inert tubes, and thus the circulation stagnates. It would seem probable, then, that inflammation takes place in this manner. Nature is able to repair injuries in living bodies only through the medium of the circulation, influenced no doubt by the nerves, which allow the arteries to dilate, or cause them to contract, and thus at times to receive greater or less volumes of blood. Whenever then any part is threatened with loss of vitality, from an irritating or sedative cause, the resistance which naturally takes place is the pouring of a larger volume of blood to the part; and, as the intention is that of reparation, so it would seem those arteries allow themselves to be dilated most readily which are for the nourishment of the part, whilst a stop is put to all secretions, by which, part of the blood in the organ would be drained off. It seems then probable, by observing what takes place in the frog’s foot, that those arteries which would not convey red blood before, now become dilated beyond their power of recovery, as is the case sometimes with the urinary bladder, and that this is the real distinction between mere increase of action where there is no inflammation, as in pregnancy, rutting seasons of animals and growth of the stags’ antlers, and the state in which real inflammation is present, this may help to show why effusions of any sort abate or cure the inflammation, it being by unloading the vessels and allowing them to recover their natural tone and calibre; this state of distension may be noticed in inflammations of the eye, especially when they assume a chronic form.

SECT. III.—OF SYMPTOMATIC FEVERS.

Symptomatic fevers of different sorts are present in most inflammations, according to the nature of the part attacked. These are caused by the sympathising of the entire frame with the action that is going on in the part affected.

1. *Sympathetic inflammatory fever.*—The symptoms are, a frequent, strong, and full pulse; diminution of the secretions; a hot dry state of the skin; scanty high-colored urine; dry furred tongue; thirst; disturbance of the nervous system; loss of appetite and sleep; in some cases delirium. The febrile symptoms appear in this form when any considerable pleuropneumonic inflammation affects common parts, and the integuments in any situation in the body, the

disturbance of the system being in a great measure proportioned to the extent and violence of the local affection.

The effects of inflammation on the constitution, however, are not simply proportioned to the quantity of inflammation; they are influenced as much by the nature of the parts in which it is situated as by its extent. When muscles, cellular membrane, skin, &c., are inflamed, the pulse is, as we have described, strong and full. These may be said to be common structures.

If the inflammation be in tendinous, ligamentous, or bony parts, the stomach sympathises more than when muscles, &c., are inflamed. The pulse is quicker, but has not so much fullness, and the blood, not being propelled so far into the small vessels, forsakes the skin. When inflammation is in vital parts, or such as sympathise with the stomach, there is great depression blended with the constitutional symptoms, the pulse is frequent and small, and the blood is not pushed into the minute vessels. A very remarkable depression of strength very frequently attends an inflammation of the intestines, and the pulse is small and hard; whereas, when the surface of the body is the seat of the affection, there is often a temporary augmentation of tone, with a full, strong, and hard pulse. In fact, when the peritoneum and intestines are inflamed, the patient frequently seems so reduced, and his pulse so small, that the surgeon is afraid to use the lancet. Perhaps, however, he at length ventures to do so; the blood appears exceedingly sily, and the pulse gains strength, in proportion as the disease yields to, and is benefited by, the evacuation.

It is a very curious fact, remarked by Mr. Hunter, that all inflammations of parts, which derive their nerves from the great sympathetic nerve, occasion an unusual lowness of spirits. When the constitution is good, and parts not very essential to life are inflamed, the pulse becomes increased in strength and fullness. When the same parts are affected in weak irritable persons, and in women who lead sedentary lives, the pulse is quick, hard, and small, at the commencement of the inflammation, just as if vital parts were concerned. Thus we see that all the varieties of inflammatory fever depend chiefly on four circumstances; viz. the extent of the inflammation; the structure of the parts affected; their functions; and the nature of the constitution.

Treatment.—It is obvious that by taking away the cause we must mitigate this fever, so that we ought to direct our attention chiefly to the local injury. But it is possible that the fever may run so high as to have a bad effect on the diseased part, in which case we must bleed from the arm, administer purgative medicines (so that no further source of irritation may arise from the faulty intestinal action), and diaphoretics, chiefly antimonial.

2. *Hectic fever* arises in consequence of long continued suppurations, from the inability of the system any longer to supply the constant drain without using an extraordinary exertion,

and not as the old surgeons supposed from absorption of pus. Its symptoms are a soft frequent pulse, profuse sweats, particularly at night; great debility; tongue moist; urine copious, with great deposits; generally of a pinkish white color; failure of appetite; and, when the disease becomes fully formed, there are frequent attacks of diarrhæa, with sudden chills and flushes of heat. Mr. Hunter has noticed that there are two practical varieties of hectic fever. The first arising entirely from a local complaint in a good constitution, which is only disturbed by too great an irritation; and a hectic fever, arising principally from the badness of the constitution, which does not dispose the parts to heal. In the first species it is only necessary to remove the part (if removable), and then all will do well; but, in the second, nothing is gained by a removal of the part, unless the wound made in the operation is much less, and more easily put into a local method of cure; by reason of which the constitution sinks less under this state and the operation together, than under the former one. Here the nicest discrimination is requisite.

Treatment.—We cannot expect to cure this fever without first healing the abscess, and, as this is frequently impossible, we must content ourselves with mitigating it only. No medicine, not even bark itself, has any direct power of communicating strength to the human constitution. All that can be done in the treatment of hectic fever, when it is thought inexpedient or impracticable to remove the morbid part, is to combat particular symptoms, and to promote digestion. It is by bringing about the latter object that bark is useful in these cases. The infusum cinchonæ, being more apt to agree with the stomach than the decoction or powder, should generally be preferred. Nourishing food, easy of digestion, should be frequently taken in small quantities at a time. Nothing is more prejudicial to a weak constitution than overloading the stomach. Wine may also be given, but not too freely, and not at all if it should create heartburn, as it sometimes does in hectic patients. Madeira is less apt to have this disagreeable effect than port. In these cases it is likewise often found useful to administer gentle cordial aromatic draughts. But, of all medicines, opium is perhaps the most valuable to those who are afflicted with hectic fever; it alleviates pain, procures sleep, and checks the diarrhæa, which so frequently attends such cases.

When the hectic fever arises from local diseases, in parts which the constitution can bear the removal of, the morbid part should be taken away, if it cannot be cured consistently with the advice already given. When the disease arises from some incurable disease, in an extremity, all the above-mentioned symptoms cease almost immediately after the limb has been taken off. A hectic pulse, at 120, has been known to sink to ninety in a few hours after the removal of the hectic cause. Persons have been known to sleep soundly the first night afterwards, who had not slept tolerably for several preceding weeks. Cold sweats have stopped immediately, as well as

those called colliquative. A purging has immediately ceased, and the urine began to drop its sediment.

These are the principal fevers met with in surgical cases: but others do occur. Thus, in inflammations of the veins, a fever resembling typhus supervenes; and Mr. Brodie remarks that, when putrid matter is confined in an abscess, it causes symptoms of the greatest malignity, which will entirely disappear on evacuating the fluid.

Having now given some account of the phenomena it will be requisite to consider

SECT. IV.—THE TREATMENT OF INFLAMMATION AND ITS SEQUELS.

This consists in unloading the arteries of the affected part, which may be done in several ways.

1. *By diminishing the general volume of blood in the body.*—For which purpose the best and most efficacious remedy is blood letting from the arm or other large veins, or the temporal arteries. This is, however, only requisite when the symptoms are violent. It has been known and practised as a valuable remedy from the days of Hippocrates. In the repetition of general blood letting we should be guided rather by the symptoms than by the buffy appearance of the coagulum of blood.

The next method in point of efficacy is local bleeding, which may be performed either by leeching, cupping, or scarifying, the part. Inflamed parts, however, do not bear this last operation well during the early stages, but it is frequently performed afterwards with good effect, as in ophthalmics. This is a most excellent and manageable remedy, as it not only unloads the system in general, but more particularly the vessels of the affected part. It therefore will in most cases be the preferable remedy, as general bleeding need only be resorted to when the constitution is much distressed.

Another very useful auxiliary is the use of purgatives (except in cases where their employment is prohibited). These act in several ways:—1st, They remove any source of irritation in the bowels from confined matters. 2dly, They increase the secretions from the mucous surface of the intestines, and so materially assist in lessening the volume of circulating fluids by the copious watery evacuations which are produced. This at the same time does not tend to weaken the patient nearly so much as blood letting.

2. *Restoring the secretions.*—Perspiration. This end is answered effectually by the use of diaphoretic medicines, such as antimonials, either with or without calomel. This last preparation seems to have a peculiar influence over the process of inflammation, and therefore deserves our most serious consideration. This we particularly notice in cases of iritis, which seems to yield to no other remedy. Of the specific actions of calomel, as well as of very many other medicines, we as yet know little or nothing. Physiologists and others have in vain attempted to explain them. All, however, that we do know of calomel is, that it affects the absorbent system by causing an increased action in it, as indeed it does in

the vascular system generally, and also acts particularly by rousing the liver and salivary glands, the secretions of which it materially augments. The last symptom indeed is a certain sign of its having affected the constitution, and is a guide for its further employment.

3. *Lessening the force of circulation.*—This may be effectually done by keeping up a constant nausea of the stomach by emetic medicines exhibited in small doses, or by remedies which act directly as sedatives to the heart's action. Such are conium, digitalis, belladonna, &c.: great caution is required in the use of these last, as they are apt to accumulate by repetition of doses, so that they act suddenly in a very powerful manner as narcotic poisons.

4. *Local applications.*—The most valuable of these is cold, in the form of lotion or pounded ice, laid over the inflamed part; which, by condensing the volume of fluid, must materially diminish its bulk, and so admit of its action in another manner, which is constringing the vessels, thereby lessening their diameter. Cold also acts as a sedative to the nerves, where the action is not too violent. In which cases cold cannot be borne. It is then that we find the employment of warm applications so serviceable, particularly combined with moisture. We see this commonly in cases of inflamed testicle or incipient acute ophthalmics. Sir A. Cooper thinks they act by producing relaxation, opening the pores, and allowing the perspiration to exude. The best mode of applying heat is by a steam bath, which may be made at the moment by placing a common strainer over a pail of boiling water, upon which the patient may rest his limb, which is then to be covered up with flannel, so as to prevent the egress of the steam; or he may have a flannel pipe leading to the spout of a boiling vessel, dilated at the end intended to be applied to the body by a circular piece of cane or whalebone. The most common way, however, of applying heat is to foment with flannel dipped into warm water, otherwise to apply a poultice made of some substance which can retain heat; for this purpose linseed meal is commonly used.

5. *Counter irritation* is often of value in checking inflammation, by drawing a quantity of blood to the part on which we produce it, and thus relieving the inflamed part of a portion of its blood. It is, however, more serviceable in chronic inflammation, or when the first violence of the acute is abated. Indurations very frequently remain after inflammations; they are to be got rid of by diminishing the circulation of the part, and promoting absorption. For this purpose the best remedies are pressure, friction, electricity, and mercury.

When all the means for subduing inflammation have been used, and fail, the most frequent sequel is suppuration; the symptoms of which having been already described, it only remains to notice the *treatment*. When we find a part beginning to suppurate it is best to use warm applications. These relieve the pain by relaxing the parts around, which thus allow themselves to become distended by the abscess without resistance. It is probable, also, that the heat may ex-

cite the absorbents to a more steady action, and thus hasten the ulcerative process. When, at length, an abscess does present itself, it becomes a question whether the surgeon should interfere or not. It will be best as a general rule to leave all abscesses to burst of themselves which by remaining unbroken can do no mischief.

The cases for the surgeon's interference are chiefly, i. Cases in which it is of consequence to save the skin from being much disfigured, as in scrofulous glands of the neck in females, which would else follow the course of all abscesses, viz., increase in size, and thus expose a greater surface to ulceration. Sir A. Cooper recommends these to be opened by a lancet transversely to the axis of the neck, as the scar will then be hidden amongst the folds of skin.

ii. All abscesses under fasciæ, which must necessarily bind them down and cause them to burrow amongst the adjacent textures, ought to be opened by the lancet or scalpel as soon as the surgeon can convince himself of the presence of matter. These are most common in the thigh, arm, and perineum.

iii. All abscesses pressing on bones should be speedily opened, as they are else apt to occasion the death or ulceration of the part. This is particularly the case with the bones of the cranium.

iv. Abscesses in parts of loose texture; where they are, on that account, very liable to spread, as near the anus, &c.

v. Abscesses pressing on either vital parts, or such as are of much importance, as the brain, eye, &c.

Surgeons used formerly to open abscesses with caustic and setons, but now these are very seldom used, the lancet or scalpel being generally far preferable. The caustic potash may be employed when the skin is sure to slough afterwards. Care should be taken in opening collections of matter to make the orifice in as depending a situation as possible; so that the pus may have a ready vent. Much, however, must depend upon the relative thinness of the skin.

After treatment.—When an abscess has burst of itself, and it is unnecessary to enlarge the opening, all that is requisite is to keep the surrounding parts clean. The continuation of the same kind of poultice, which was before used, is, perhaps, as good a practice as any; and when the tenderness, arising from the inflammation, is over, lint and a pledget may be made use of, instead of the poultice. But an abscess, opened by a cutting instrument, is both a wound and a sore, and partakes more of the nature of a fresh wound in proportion to the thickness of the parts cut. Hence it is necessary that something should be put into the opening to keep it from healing by the first intention. If it is lint, it should be dipped in some salve, which will answer better than lint alone, as it will allow of being taken out sooner. This is advantageous, because such sores should be dressed the next day, or, at latest, on the second day, in order that the pus may be discharged again. When the cut edges of the opening have suppured, which will be in a few days, the future dressings may be as simple as

possible; for nature will, in general, complete the cure.

Healing of abscesses.—This takes place by granulation. Thus when an abscess is opened, or when a wound has been produced, if the edges are not brought together, inflammation is excited; and this inflammation occasions an effusion of the fibrin of the blood upon the surface of the wound. This fibrin is poured out in a layer upon the surface, and soon becomes vascular; for blood-vessels, which are elongations of the vasa vasorum of the divided vessels, are forced by the action of the heart into the fibrin which has been deposited. The fibrin which is thrown out, besides the purulent secretion from the vessels, forms a second layer, into which the vessels shoot as before. The vessels supporting the first layer are the means of supporting the second layer, where the vessels terminate as before, by open mouths on the substance effused. In this manner layer after layer is formed, until the cavity becomes filled.

Of chronic abscesses.—These demand a little separate consideration. For, 1. Their general treatment should be directly opposed to that of acute ones; for here the patient must be allowed a generous diet and tonic medicines. 2. Their local treatment differs very materially, as they often require stimulating applications to bring them forward; such as poultices of oatmeal and yeast, or flour and vinegar wetted with a solution of common salt; or plasters, as the compound galbanum or mercurial, with ammoniacum, and soap plaster. When suppured they are to be opened as the others. Care must be taken, however, to prevent access of air or violence to large cysts; which, under these circumstances, may inflame and produce symptoms of malignant fever. When, however, the cysts are small, as in scrofulous glands, we should take care to squeeze out all the flakes of unorganised matter, which will facilitate the healing.

It should be observed that abscesses situated over diseased substances, as bone or glands, cannot heal till these last are either removed or cured. Also when situated so as to be kept in motion they heal with difficulty. When matter has penetrated far in a longitudinal direction under the skin, we say there is a sinus. This is often observed under fasciæ or about the rectum. These may often be cured by pressure; which should, indeed, be applied gently or gradually to all cysts of chronic abscesses. When, however, pressure will not remove them, they must be laid open and dressed to the bottom.

We come now to consider the treatment of the last sequel of inflammation.

SECT. V.—GANGRENE.

In treating this there are two indications. 1. To put a stop to its progress. 2. To separate the dead from living parts.

1. When gangrene is threatened from severe inflammatory action, all applications, says Mr. Hunter, should be cold till the excessive action be somewhat subdued. Cold, however, cannot be persevered in too long, as it then becomes a cause of gangrene. Whilst the constitutional

symptoms are violent, blood may be taken locally or generally; but, if they threaten exhaustion, opium with cordials must be administered and bark will now prove efficacious. When gangrene has formed, then we should endeavour to save the neighbouring parts by stimuli, which prevent the stagnation of blood in the vessels and enable them to resist the gangrenous action: for this purpose poultices of stale beer grounds with linseed meal, port wine poultices, spirituous application, yeast, vinegar, camphor, turpentine, charcoal, and carrot poultices, are all useful. Some surgeons preferring one and some another. 2. When a slough or sphacelus has formed, and the constitution has tone enough, it will be separated from the living parts; so that the surgeon need only await the result, except, indeed, it should occur under the skin, or where the egress is difficult, as in cases of effusion of urine into the scrotum. Here the surgeon must make free scarifications down to the sound parts; so as to allow it the most ready exit. In common cases, however, as in the extremities, a line is formed between the living and dead matters. We should then apply the less violent stimuli, and nature will generally make a tolerably good stump; so that all the surgeon need do, is to saw through the bone, unless the surface be left very ragged and uneven, as is sometimes the case, on account of the different degrees of vitality of parts. Thus tendons or membranes are less vital than skin and muscle, and so often slough to a greater extent. In this case the surgeon had better perform amputation when the patient is able to bear it. As a general rule amputation should never be practised whilst the mortification is spreading, as in these cases the stump is very liable to slough also. But the baron Larrey, in his *Memoirs de Chirurgie Militaire*, says that in cases where gangrene is the result of a mechanical cause, and puts the patient's life in danger, amputation ought to be performed without waiting till the disorder has ceased to spread guided by the maxim of Celsus; that an uncertain remedy is preferable to abandoning a patient to certain destruction.

There is another case, noticed by Mr. Sharp in his *Critical Enquiry*, in which amputation ought not to be performed; viz., in mortification of the toes and feet in old persons; for, as this depends on an ossified state of the arteries and consequent incapability of nourishing the lower limbs, we cannot expect the stump to be in a better condition than the toes were. In treating this loathsome complaint, Mr. Pott observes, we should avoid stimuli, as the vessels cannot bear increased action, and apply only warm and soothing dressings.

In cases of mortification from the effects of cold we must beware of too sudden a stimulus. Sir A. Cooper says, if gangrene is likely to arise from the application of cold, the treatment must be different: in these cases the action of the parts is feeble, from the diminution of nervous power, and it will be proper to restore it to a healthy state by stimulants of the most gentle kind. For this purpose the best application is the camphorated spirit of wine, accompanied with gentle friction. If you are called to a patient

whose feet are benumbed from the effects of cold, you must sit by his bed-side, pour camphorated spirit into your hand, and rub it on his feet with the utmost gentleness, so that the part may not be irritated by violent friction. When the first effects of cold are removed, it will be proper to apply cold poultices; for warm applications are to be carefully avoided. When parts are frost-bitten, in colder climates, the common practice is to restore the circulation by rubbing them with snow.

Hospital gangrene must not be confounded with ulcers from scurvy, which generally occur with the other symptoms of this last disease, as, bleeding gums, blotches on the skin, &c., and are benefited by vegetable acids and fresh diet. The most efficacious treatment seems that recommended and practised by the French surgeons Boyer, Dupuytren, &c., who make a firm, hard eschar, by the application of the actual cautery to the ulcers, which they repeat if the wounds reassume gangrenous action. These surgeons have no confidence in constitutional remedies for this complaint. When the disease is stopped, it is notified by the appearance of a phlegmonous swelling at the circumference of the ulcer, for which Boyer recommends at first a poultice, but as soon as pus is secreted this is too relaxing. He then enjoins some mild tonic, as the decoct. cinchonæ.

There is another disease which, bearing considerable analogy to phlegmon, demands our next attention. This is

SECT. VI.—ERYSIPELAS.

Erysipelas, ερυσω, to draw, πελας, adjacent, or St. Anthony's fire, derives its first name from its tendency to draw the neighbouring parts into the same state; it was known first by this name in the time of Aretæus. According to the doctrines of Pythagoras, it was supposed to be formed by bilious humor, and, as a disease, was well known to Galen. The cause of this formidable malady seems to be an inflammation of the skin and subjacent cellular structure; it differs, however, materially from phlegmon, both in symptoms, and in its not attacking alike all structures, being confined to the skin; or, as Dr. Cullen supposed, to this and mucous membrane. This disease presents itself in two very different forms, with, however, every degree of modification between them, one acute or phlegmonous, the other atonic.

Symptoms.—General. An attack of erysipelas is mostly preceded by considerable constitutional disturbance, particularly nausea and headache, with great derangement of the digestive organs, and is ushered in by a shivering. Then a red spot appears, which soon spreads rapidly, causing a little elevation of the skin, not circumscribed, but often with a well defined edge between it and the healthy parts; its color is a bright red, more or less tinted with brown, which, on pressure, vanishes, leaving a white spot, but which quickly regains its color. It is attended with a burning pain; not throbbing as in phlegmon. We shall now consider its two varieties,

1. *Phlegmonous, or acute.*—In this the constitutional symptoms assume the form of inflami-

matory fever. The eruption is of a brighter red, pulse full, urine high-colored, great pain in the head, and frequently delirium. It generally terminates favorably in four or five days by the appearance of little vesicles, or desquamation of the cuticle; or, if violent, an abscess may arise and burst. When not very severe, this disease frequently leaves the part first attacked, and settles on some other. It is particularly dangerous on the face, as the membranes of the brain then often become inflamed.

Treatment.—1. General. This must depend on the constitutional symptoms; if they are violent, bleeding generally must be resorted to. Local bleeding has been recommended, but it is apt to aggravate the irritation of the affected part, whether leeches, cupping, or scarifying, be used. Calomel, with mild purgatives and diaphoretics, seem the best remedies, and, indeed, it may be treated as any other fever. 2. Local remedies in this variety are not of so much importance. But, on the whole, cold applications are most serviceable. Greasy applications, as ointments, have been recommended, and often prove beneficial. Fine hair powder, during the vesication, is comfortable to the patient; it is chiefly useful in absorbing the discharge.

2. *Atonic erysipelas.*—In this variety the fever is much of a typhoid appearance. It is in general not so acute at first as the other, but more gradual in its approach, mostly, however, preceded by shiverings. There is a cold and clammy skin, pulse weak and irregular, eruption of a deep reddish brown, with vesication from its commencement, vomiting, and low delirium. This variety is exceedingly apt to end in sloughing and imperfect suppuration of the subjacent cellular texture, extending even under the fascia, which soon contaminates the superincumbent skin, if it be not allowed a ready exit. The cellular texture is more liable to gangrene than the skin, because it has less vitality. This state of things may be known by an œdema of the part, with a doughy feel, and crepitus.

Treatment.—On nothing have surgeons more disagreed than the treatment, both local and constitutional, of this formidable malady, which in itself must argue much inherent malignity and variety of disease. Some have recommended stimuli from the commencement, and particularly bark, but most modern surgeons prefer waiting till the violence of the fever is over before they commence with this then efficacious medicine. In the early treatment an emetic seems of much benefit when there is disturbance of stomach or liver. This may be followed by gentle stimuli, as ether, camphor, ammonia, &c., in proper forms, and if the patient be very low we must admit of wine or brandy.

Local treatment.—In this variety cold is not admissible, but rather any thing which will assist in supporting the vitality, as warm spirit lotions, or, what are better, Port wine lotions, made with one part of wine and two of water, or an imitation of it thus:—R. Sp. vin. rect. ℥iv. Decoct. papav. ℥vi. Decoct. quercûs, ℥vi. mfil., lotio. sapæ tipida. applicanda. Poultrices are generally too heavy to be borne without a great deal of pain.

When sloughs or pus have formed under the skin, the sooner they are allowed to escape by free incisions the better, as, by this means, we avoid the constitutional irritation they would cause, and save the skin above the slough from dying. Many modern surgeons have gone so far as to make free incisions in the first instance, long before any slough can have formed, but this practice seems unnecessarily severe.

Causes of erysipelas.—There can be no specific cause assigned for its origin; but it generally attacks those whose chylopoietic viscera have lately suffered, but no constitution seems exempt. It frequently assumes a contagious character, as we see in hospitals, where at times it will attack nearly all wounds in them; and it is to be remarked that wounds seem always an exciting cause, even when of the most trivial description, as a scratch or leech bite.

CHAP. II.—OF WOUNDS.

Wounds are solutions of continuity in the soft parts, occurring suddenly; they may be either of a simple nature, or complicated with other injuries or lodgment of foreign bodies; their danger must depend considerably on their size, and relative importance of the part. Thus, wounds of the brain, heart, or stomach, of very small size, prove fatal. Some textures also are less able to bear injuries than others: of this nature are joints, of which all wounds are attended with danger. But a point of great consideration, in the estimation and treatment of wounds, is the degree of violence done to the parts, besides their mere separation.

Wounds may be healed in two manners, 1. Union by first intention; 2. Suppuration.

1. *Union by first intention.*—Is the natural process of uniting divided surfaces, and is effected in the following manner:—The sides of the wound must be in immediate contact; with no foreign body intervening (in this case even a clot of blood which has been long extravasated becomes a foreign body by having thus lost its vitality). Then there takes place an effusion of coagulating lymph from the adjacent parts, which from non-exposure, being yet vital, soon becomes vascular, from the neighbouring vessels being elongated into the clot, which thus becomes the living bond of union between the cut surfaces.

2. *Suppuration.*—Is a much slower process, and consists of an effusion of pus from the sides and bottom of the wound, which thus becomes an ulcer and heals by granulation.

Wounds may be simple or incised, punctured, lacerated, contused (comprising gunshot wounds), or poisoned.

SECT. I.—SIMPLE OR INCISED.

The simple or incised wounds are, cæteris paribus, the least formidable of all; they are also least liable to the presence of foreign bodies, except such as are cut by glass. These should always be attempted to be healed by the first intention, having previously removed any foreign body (if any be present). They may, however, be complicated with other injuries; thus they may extend into a joint, which is known by the es-

cape of synovia and their position, in which case, if it do not heal by the first intention, the joint swells, violent inflammatory fever supervenes, and, if the patient survive the violence of the attack, an abscess is formed in the joint which often destroys those cavities. In very favorable cases, however, the secretion of pus gradually diminishes, and the joint recovers its function. In treating these cases, it is obvious that we should endeavour to get union by the first intention, and to this end the surgeon should be very careful not to irritate by over officious probing. If, however, inflammation supervene, we must use the most active means already recommended for the subduing of inflammations, viz. repeated bleedings, both general and local, and keeping the patient in a constant state of nausea and depression. If abscess form, its treatment does not differ from common abscesses: we should allow it to burst and offer no violence to it. If ankylosis be threatened, we should try to place the limb in the most favorable posture for use; and if long continued suppurative supervene, which is gradually wearing away the patient's health, we must have recourse to amputation.

Another most serious and common complication of wounds is the occurrence of

1. *Hæmorrhage*, of *αἷμα*, blood, and *πῶς*, to flow. This is always more formidable when occurring from an artery than a vein; for the latter may generally be secured by pressure, unless it be from a very deep and large trunk, in which case it will be necessary to tie it with a ligature of silk. When an artery, however, is wounded, it bleeds with much greater velocity than a vein, as it comes direct from the heart. It may be known by the florid color of the blood. If a wounded artery be small, it will often cease bleeding spontaneously; this happens through the contraction of the wounded artery, and a coagulum forming in the end of it. This then being the natural process of stopping bleedings from small arteries, it is obvious that if the artery be divided only partially or punctured, it cannot contract, and so will continue to bleed; in this case it will be best, if the artery be small, to divide it entirely. This was known to and advised by Ambroise Paré, the father of modern surgery. But, when an artery of larger size be wounded, the force of the circulating fluids prevents its contraction, and, having no valves like the veins, it will bleed from both its upper and lower ends, by its anastomosing branches, enlarging and bringing the blood again into the trunk below the wound. To stop arterial bleeding many remedies are practised. Styptics are of very little service, except for small vessels and from veins; lint should be dipped in saturated solutions of them, and applied to the parts. They are, however, useful after operations in checking the oozing of blood, which might exhaust a patient already enfeebled by loss from larger vessels. But in these cases they are not admissible, where union by the first intention is attempted.

2. *Pressure* is a remedy of great value, especially in wounds of many smaller arteries, which either cannot, or would occupy too much time and space to be tied. In this case we should

not fill up the wound as the older surgeons did. But this is executed by applying a bandage, and compresses in such a manner that they mechanically stop the effusion of blood. Formerly surgeons used to fill the cavities of wounds with lint, and then make pressure on the bleeding vessels, by applying a tight roller over the part. The moderns understand too well the utility of not allowing any extraneous substance to intervene between the opposite surfaces of a recent wound, to persist in the above plan, except in a few instances. They know that the sides of the wound may be brought into contact, and that compression may yet be adopted, so as both to restrain particular hemorrhages, and rather promote, than retard, the union of the wound. When the blood does not issue from any particular vessels, but from numerous small ones, compression is preferable to the ligature. The employment of the latter would render it necessary to tie the whole surface of the wound. In order to make effectual compression, in this case, the wound is to have its opposite surfaces brought into contact; compresses are then to be placed over the wound, and a roller is to be applied as tightly as can be done, without hazard of stopping the circulation in the part.

Pressure is also sometimes made on very small openings into larger sized arteries when they run near bones on which they can be compressed. This is often practised in wounds of the humoral artery from bleeding; in which case the wound may heal, but in most instances the artery will be obliterated; but not necessarily so, as Dr. Jones proved. If, however, this plan do not succeed, then we must cut down, expose the artery, and tie both ends.

3. *Ligature* must be used in all cases of wounded large arteries, which cannot be compressed against bone, where there is time to apply them. They must be applied both above and below the wound, and should be of silk, drawn tightly so as to rupture both the inner and middle coats of arteries. This causes inflammation of the vessel, and effusion of lymph, which prevents hæmorrhage when the ligature comes away by ulceration, which happens in from two to fourteen days, depending on the size of the artery. Care should be taken in tying large arteries not to detach them too much from their surrounding connexions. When a ligature has been applied, one end should be cut off close to the vessels, leaving only one portion of extraneous matter in the wound instead of two. Some have recommended a very fine ligature to be used, and cut off close to the vessel, and the wound healed over it; but this is generally found to cause suppuration—sometimes, however, not of large extent or importance.

4. *Actual cautery* was in very common use amongst the ancients. It is very painful and inconvenient; but its chief disadvantage is, that the part to which it is applied must slough, causing a tedious suppurating wound which, on the separation of the slough in the first instance, is liable to bleed again. There are some cases, however, in which even this is serviceable; such as bleeding from the mouth, or parts where the

vessel cannot be got at and tied. In these cases it should be applied through a canula, so as to protect the surrounding parts. It must also be used in extirpating large tumors where the surgeon has not time to tie the vessels on account of their number and size, and the deluge of blood which they are pouring out; such are fungous growths from the dura mater, &c.: or, again, when it is wished that the parts adjacent to the removed part should slough, as in malignant tumors, when it is difficult to extirpate the whole of the disease otherwise.

FURTHER REMARKS.—i. When a hæmorrhage takes place from arteries, if left alone, it will continue till the patient faints, in which case, as the heart ceases to propel the blood, no more escapes, whilst the faintness continues; and now a coagulum often forms in the mouth of the divided artery, of sufficient size and firmness to stop the exit of blood when the heart may resume its action, and thus the patient's life is saved. This often happens, on the field of battle, in sabre wounds; for, were it not for this beautiful provision of nature, every one with a wounded artery of any size must perish.

ii. When an artery is torn, and not cut, it is found that the disposition to hæmorrhage is materially diminished; and very often, as in gunshot wounds, even when a main artery of a limb is torn across, there follows scarcely a drop of blood. Mr. C. Bell explains this phenomenon as follows:—He believes that the fluidity of the blood depends upon its contact with the inner coat of arteries; and there are many circumstances which would make this appear probable. In lacerations, then, of arteries, it must happen that the inner coat, being the least elastic of the three, is torn away to greater or less extent, leaving the outer one projecting; the blood then, being in contact with the outer coat, coagulates, and stops the bleeding.

iii. When a hæmorrhage takes place from ulcerated morbid growths, it is sometimes impossible to stop it without removing the tumor; for, if the bleeding vessels be even tied, they will (through partaking of the disease) presently ulcerate, without producing adhesion, and the bleeding returns: if however the tumor be removed, we then come to the artery in its healthy state, and tying can now be safely practised.

Having now considered hæmorrhage, we come to the means by which incised wounds are to be united.

1. The position of the part should be attended to. This is to be regulated on the principle of relaxing the wounded integuments and muscles. If the extensor muscles be injured, the joints which they move ought to be placed in an extended posture; if the flexor muscles be wounded, the limb is to be bent. When the integuments alone are cut, the same posture which relaxes the muscles situated immediately beneath the wound, also serves in general to relax the skin. In transverse wounds of muscular fibres it is astonishing what immense effect the observance of a proper posture produces. This is never to be neglected, whatever may be the other means adopted.

2. Adhesive plaster is generally applied in

strips, between every two of which an interspace is recommended to be left for the purpose of allowing discharge to escape. To bring the edges of the wound effectually together, and at the same time to cover as little of the wound as possible, are the objects to which we ought to attend in using adhesive plaster. Hence, when the strips are broad, it is not unfrequent to cut out an oval piece of each strip, just where it crosses the wound.

3. Bandages are often serviceable, besides the mere adhesive plaster; for they support the parts around, and hinder them from gravitating on the wound; and so keeping up a constant tendency to separation of the lips.

4. Sutures. One only is employed by most modern surgeons, viz. the interrupted, which consists of one or more separate stitches, taken with a curved needle and ligature, each stitch being tied, and the ends cut off close. These are only used to assist the adhesive plaster in cases where there is much opposition to the contact of the lips of the wound, and where a bandage will not have the effect. It is generally used where there has been loss of structure. Their employment is always regarded with a jealous eye by modern surgeons, as they naturally irritate the wound, and sometimes seem to produce erysypelas.

SECT. II.—OF PUNCTURED WOUNDS.

Mr. S. Cooper says punctured wounds are not only dangerous on account of their frequently extending to a considerable depth, and injuring important blood-vessels, nerves, and viscera, they are also dangerous inasmuch as they frequently give rise to very extensive inflammation. It is not uncommon to see formidable collections of matter follow wounds of this description, especially when the instrument with which they have been made, has penetrated any aponeurosis, or fascia. Stabs, and all other punctures, are not simple divisions of the fibres of the body, they are attended with more or less contusion and laceration. Hence there is not the same readiness to unite, which we observe in wounds made with sharp cutting instruments; and, when ligamentous expansions are among the objects of injury, both the structure of the wounded parts, and the nature of the wound itself, often produce a train of severe local and constitutional symptoms. When an artery of consequence is punctured, the hæmorrhage must be suppressed either by exposing the vessel and tying it, or by applying graduated compresses and a bandage. Punctured wounds are frequently very difficult and tardy of cure, on account of their being attended with the formation of deeply-seated abscesses and sinuses. The narrowness of their orifices also renders the extraction of any extraneous bodies by no means easy of accomplishment.

Treatment.—It has been recommended by many writers, who erroneously confounded these recent wounds with true fistula, to lay them open, pass setons through them, and irritate them by stimulant applications; but this treatment is quite contrary to the true practice, when we consider the inflammation is almost

sure to follow, without any additional irritation, which then can only do mischief. In our treatment then, in the first stage of a punctured wound, the indication is to guard against the attack of violent inflammation. When no considerable quantity of blood has been lost, general and topical bleeding should be practised. In short, the antiphlogistic plan is to be followed. As no man can pronounce whether such wounds will unite or not, and as no harm can result from the attempt, the orifice ought to be closed with strips of adhesive plaster, and gentle compression applied along the whole course of the puncture. Perfect quietude is to be observed. When the pain is very severe, opium is to be administered. Sometimes, under this treatment, the surgeon is agreeably surprised to find the consequent inflammation mild, and the wound speedily united by the first intention. More frequently however, in cases of deep stabs, the pain is intolerable; and the inflammatory symptoms run so high as to leave no hope of avoiding suppuration. In this condition an emollient poultice is the best local application: and, when the matter is formed, the treatment must conform to the principles already noticed in the chapter on suppuration.

SECT. III.—LACERATED AND CONTUSED WOUNDS.

Lacerated wounds are those in which the fibres, instead of being divided by a cutting instrument, have been torn asunder by some violence, capable of overcoming their force of adhesion. The edges of such wounds, instead of being straight and regular, are jagged and unequal. The term *contused* is applied to those wounds which are occasioned by some blunt instrument, or surface, which has violently struck a part of the body. These two species of wounds greatly resemble each other, and, as they require nearly the same kind of treatment, writers usually treat of them together.

Both these sorts of wounds are much more perilous than incised ones. Wounds made with sharp instruments are frequently attended with vast retraction of the divided parts, and profuse hæmorrhage; but it is known, at the same time, that they are generally capable of being united by the first intention. It is almost a constant effect of lacerated and contused wounds to pour forth very little blood, even when important blood-vessels have been injured. Whole limbs have been torn from the body without the occurrence of bleeding. The experienced practitioner is not deceived by the absence of this symptom; for he knows that, in proportion as the bleeding from large contused and lacerated wounds is trivial, the violence applied to the injured parts has been great. The pain is generally in an inverse ratio to the extent of mischief done.

Treatment.—In a lacerated wound, not caused by gunshot, we cannot expect that total adhesion by the first intention will take place, but rather inflammation and suppuration, notwithstanding which we should approximate the edges by sutures or plasters, and let it take its chance, leaving it afterwards as its appearance may indicate. But in contused wounds, as gunshot,

we know that the surrounding parts have received so much injury that they must of necessity slough to a greater or less extent. In treating them, we should first remove any extraneous body, if this can be accomplished without much force; then endeavour to abate the inflammation around, which will necessarily arise; for this, we may bleed locally or generally, as the symptoms demand. The best application to the part is a poultice, till the sloughs come away, after which the simplest dressings possible. It is seldom, if ever, good practice to dilate openings caused by bullets; nor should we use violence in attempting to extract them. When they have wounded a large artery, we must then cut open and tie it. But in severe lacerations, when it is obvious we cannot save the limb, from the amount of injury done, we must amputate as soon as possible. In many gunshot wounds also this is necessary; and baron Larrey enumerates several cases in which it should be performed at the time of the injury without delay, in which he has been borne out by Mr. Guthrie in his excellent treatise on Gunshot Wounds. They are, 1. A limb carried away by cannon-shot, leaving an irregular stump. 2. A limb shattered by the same cause, which will else be succeeded by gangrene. 3. A ball carrying away soft parts containing the main artery of the limb without fracturing the bone. 4. Soft parts with the principal nerve. 5. Extensive fracture and injury to soft parts without lesion of skin. This is generally caused by a ball striking the part very obliquely, which was formerly considered the wind of a ball, or else by a spent ball. 6. Fractures of articulating ends of bones by balls or lodgment in joints. 7. When a bone is extensively denuded without fracture. 8. A large wound of a ganglymoid joint with effusion of blood into it. 9. Fractures of the thigh from gunshot wounds.

SECT. IV.—GUNSHOT WOUNDS DEMANDING AMPUTATION CONSECUTIVELY.

1. Spreading mortification. 2. Convulsions of wounded limbs threatening tetanus. 3. Bad state of discharge, with hectic fever happening in fractures from shot.

Wounds of the abdomen.—If large, these admit of protrusion of viscera, which must be returned either without, or by means, of dilatation of the external wound. When small, it becomes a matter of doubt whether the wound has penetrated, this must be ascertained by the finger. When a man is stabbed, or shot in the belly, the surgeon can seldom do any good by being very officious; and the wisest conduct that he can in general adopt is to keep his patient as quiet as possible, have recourse to bleeding, prescribe anodynes, and the lowest fluid diet, and content himself with applying superficial dressings. In the event of severe pain and swellings of the belly coming on, leeches, fomentations, and emollient poultices will be necessary, and nothing will now avail except the most rigorous antiphlogistic means.

Wounds of the chest are always dangerous, but may be considered less so when the pleura is penetrated alone without containing any fo-

reign body injurious to the lungs, or hæmorrhage into the cavity of the thorax. When a wound is known to have entered the pleura, and there is no symptom leading to a suspicion that the lungs, or any large vessel, is wounded, the injury is to be dressed according to common principles, and the more superficially the better. Authors also usually direct us, just before we close the opening, to tell the patient to make a deep inspiration, for the purpose of expelling as much of the air as possible, which may have got into the cavity of the pleura. At the end of such inspiration the edges of the wound in the skin are to be brought together, and kept so with sticking plaster compresses, and a roller applied round the body. The other grand indications in the treatment are to avert inflammation of the pleura and lungs, by a rigorous adoption of the antiphlogistic plan, copious bleeding, in particular, not being forgotten.

Wounds of intercostal arteries are manifest by the hæmorrhage, where the external wound is ample, or may be ascertained by putting the finger on what we suspect to be the artery, and seeing if that commands the bleeding; but, when the wound is small, the artery bleeds into the cavity of the thorax, and cannot yet be known. When it can be ascertained, most modern surgeons (condemning the old practice of putting compresses into the thorax) simply recommend cutting across the artery, and closing the external wound.

Empysemata.—This is a term applied to a swelling arising from a diffusion of air among the cells of the cellular substance. This symptom may occur in wounds which just enter the cavity of the chest; in others that extend more deeply, so as to wound the lungs; and also in cases in which these organs are wounded by the spiculæ of a broken rib, or clavicle, while there is no outward wound whatever. I believe emphysema is never very extensive, unless the air vesicles of the lungs are injured, and there is no outer wound, through which the air can freely make its escape. Hence we find that emphysema is a more common consequence of fractured ribs, and narrow stabs, than of large penetrating wounds; because, in the latter cases, the air readily passes outward through the opening.

When the chest becomes expanded in the act of inspiration, some of the air, which enters through the trachea into the wounded lung, instead of distending this organ, now passes through the breach in it, so as to get into the space between the pleura pulmonalis and pleura costalis. Dr. Halliday has very accurately remarked that, in the living body, the whole of the inspired air will not be thus effused; but that, as it must pass through the lung, it will at first distend it, more or less, according to the size of the opening in the pleura pulmonalis. This partial dilatation of the wounded lung will always happen while air continues to be inspired on that side.

When the thorax is next diminished in the act of expiration, the effused air is compressed against the wounded lung; but none of it can enter this viscus again, because the whole of the air contained in the lung must be forced out, and the effused air makes equal pressure on every

part of the organ, as this becomes *compacted*, so that it cannot separate any particular part, and make a passage for itself towards the trachea. In this manner fresh air accumulates in the space between the pleura at every inspiration, while none can escape during expiration. This case may produce suffocation from the pressure of the collected air on the diaphragm, mediastinum, and opposite lung. However as emphysema commonly follows narrow stabs, or fractures of the ribs, attended with injury of the lungs, the pleura costalis and intercostal muscles are at the same time wounded or lacerated, so that part of the air also usually gets through the above wounded membrane and muscles, into the cellular substance on the outside of the chest, and thence is sometimes diffused through the same substance, over the whole body, so as sometimes to inflate it in an extraordinary degree. The inflation of the cellular substance has been considered the most dangerous part of the disease; but Mr. Hewson very ably shows that this is a very erroneous supposition.

From what has been stated, it is evident that, in cases of emphysema, the danger does not depend so much on the degree of external swelling, as on the degree of compression produced on the mediastinum, diaphragm, and the lung of the opposite side.

Treatment.—When there is no wound of the lungs, and not as yet much air confined in the pleura, the wound had better be closed with adhesive plaster at the end of a powerful expiration. But, if the emphysema increases, we must then conclude that the lungs are wounded, and allow the air to pass and repass through the wound till the lung can heal; but, if the wound be too small, it must, if conveniently situated, be enlarged, or else another opening must be made in the chest; if on the right side, between the fifth and sixth; if on the left, between the seventh and eighth, to avoid the pericardium, and at the upper margin of the ribs, to avoid the artery. The use of making this opening is to cause the wounded lung to collapse, and so, not being used, no more air escapes from it, and the wound has time to heal, which it generally does in five or six days, and the remaining air is absorbed. Bandages round the chest are, generally speaking, improper. When the emphysema is large, it is always proper to give an outlet to the air, by making small punctures in various situations, and promoting its exit by frictions. Indeed the surgeon is always to be content with this practice, unless the symptoms of compression on the diaphragm and opposite lung, and the approach of suffocation, denote that the air cannot get out of the cavity of the pleura so quickly as it finds its way into it; in which case a small but direct opening is to be made into that side of the chest on which the wound is situated.

Extravasation in the thorax.—This is liable to happen in all cases in which the lungs, the intercostal, or internal mammary arteries are wounded. The symptoms of blood thus effused are, great oppression of the breathing; inability to stand or sit up, owing to the weight of the fluid on the diaphragm; the most easy posture is on

the affected side; but the patient cannot lie on the opposite side without great aggravation of his oppressed breathing; the respiration is short, frequent, and interrupted; the countenance is particularly pale. Together with these symptoms, which are indeed very inconclusive, the extremities become cold; a clammy perspiration takes place; and, if the lungs are wounded, frothy blood is spit from the mouth, and air often escapes from the wound. It is to be regretted that these symptoms are very fallacious.

Treatment consists in evacuating the blood. Several things which promote this end have been practised. 1. Placing the patient in such a posture is as favorable to the exit of blood from the wound. 2. Drawing the blood out by a syringe. 3. Enlarging the wound. 4. Making use of injections. 5. Making an opening at a depending part of the chest.

1. We can only expect to afford relief, by mere posture, when the wound is large, and direct in its course, and the blood is in a fluid state.

2. Syringes, to exhaust the blood out of the chest, are seldom necessary; when the blood is fluid it will escape spontaneously, on a depending opening being made; and when coagulated, it cannot be drawn out by a syringe.

3. The wound should only be enlarged when its situation is favorable for the escape of blood.

4. When the blood is coagulated, the injection of warm water is extremely proper. It should not be done with too much force; and it may be repeated every day, till the fluid returns untinged with red globules, and quite free from coagula.

5. When the wound is narrow, and situated either at a fleshy part of the chest, or at its upper part, a counter opening should be made in a depending situation.

Poisoned wounds.—The most frequent are those caused by animals or insects, such as the bee, wasp, hornet, &c., in this country. These often cause a great deal of heat, redness, swelling, and pain near the wound. The best cure, if too late to evacuate the poison by sucking, is by applying vinegar, lemon juice, Goulard's lotion, cold water, hartshorn, or oil; if stung in many places, bleed, and keep the antiphlogistic regimen.

Bite of the viper.—The bad symptoms usually commence in about twelve or fifteen hours. An acute pain and a burning heat are experienced in the part affected, which begins to swell. The tumefaction, tension, heat, and pain, gradually spread over the whole limb, and in some cases the whole body is said to be swollen. Dejection of spirits, smallness and weakness of the pulse, headache, nausea, and vomiting ensue. A fixed pain is felt in the region of the heart, and all the surface of the body assumes a yellow tinge. The urine seems as if it were impregnated with bile. Cold perspirations and convulsions take place, and death sometimes finishes the tragedy.

Treatment.—Prevention of the spreading or absorption of the poison is the only plan from which the surgeon can ensure safety; for this various plans have been proposed, the most efficacious of which certainly is the removal of the bitten part by excision, taking care not to leave any of the bite; or by the actual cautery. Oil has

been recommended by some, which must act by insinuating itself between the poison and the wound. Also cantharides, which may act by washing away the poison in the profuse discharge. Lately, however, it has been proposed to apply a cupping glass over the wound, which has a constant tendency to draw out the poison, and this has appeared to answer very well.

Constitutional treatment.—Emetics have been very much extolled by Dr. Mead, for the relief which they afford, in bringing to a conclusion the nausea and sickness arising from the bite.

But the testimony of almost all writers decides in favor of medicines which possess the faculty of allaying irritability and promoting perspiration. The volatile alkali has obtained the greatest celebrity. Ten drops of the aq. ammon. pur. may be given every hour. Opium, musk, and camphor, are other medicines, to which one may advantageously resort.

Tetanus (from *τενω*, tendo; *τετανος*, distended) demands notice in this place, from being commonly induced by wounds, particularly lacerated ones. This is commonly called traumatic (*τραυμα*, a wound) to distinguish it from the idiopathic form, which does not fall under the dominion of the surgeon.

Symptoms.—A stiffness is first experienced about the back of the neck.—The muscles of the lower jaw next become hard, and incessantly contracted, so that some difficulty is experienced in moving the part. At length the patient cannot open his mouth at all. The muscles concerned in deglutition are oftentimes the next affected, and the difficulty of swallowing makes the complaint bear some resemblance to hydrophobia. All the muscles of the neck, back, and indeed of the whole body, become successively affected with the most rigid spasm. The limbs are stiff and immovable, and, the muscles of respiration being prevented from performing their office, the patient dies. The fingers often retain their motion till the last, as does the tongue, which is sometimes thrust out of the mouth, and dreadfully lacerated by the teeth. This disease is seldom accompanied by fever, and the patient retains the vigor of his mind till nearly the last. The occurrence of this formidable disease is more common in hot than in temperate climates. The causes of tetanus remain yet unknown; and though, in some instances, inflammation of nerves or the spinal marrow have been found; yet in so many others have they been wanting that we cannot assign these as the true, though they might have been the accidental causes.

Treatment.—On this head, also, surgery must deplore its ignorance, no remedy having been yet discovered. Tobacco and opium have been used in alarming quantities without the slightest relief; mercury, bark, camphor, and musk, have proved equally inefficient; even amputating the wounded limb has been practised with no better result. In some cases, indeed, performed by baron Larrey, the symptoms were checked, but always returned and proved fatal. There is one remedy, however, which has proved useful as a mitigatory in several late cases, which is dashing cold water over the body, but this by frequent repetition becomes of no effect.

SURGERY.

SECT. V.—CONTUSIONS

Are the consequence of forceable contact of blunt substances with the body, which cause a great deal of injury to the parts underneath, without a breach of continuity on the surface.

The consequences of such violence are a diminution of the tone of the injured fibres and a rupture of an infinite number of small vessels. The bruised muscles are weakened, and cannot be exerted without pain; and the extravasation of blood causes swelling and discoloration of the skin. Sometimes vessels of considerable size are ruptured by the force, and very copious accumulations of effused blood are the result. In contusions of the head we often see the scalp enormously elevated by hemorrhage beneath it, and large collections of blood are frequently found extravasated in the cellular substance of almost any situation in the body.

The mischievous effects of a contusion are not always proportioned to the force applied; they often depend on the nature of the injured part. If the bruise take place on a bone which is thinly covered with soft parts, the latter always suffer very severely in consequence of being wounded, at the time of the accident, between two hard bodies. Hence bruises of the skin so frequently cause sloughing and troublesome sores.

Treatment.—We must endeavour to abate the inflammation by leeches, or, if it be violent, by general bleeding and cold lotions applied to the part: these last should have some stimulating power to promote the absorption of the effused blood. When muscles are bruised they should be kept quiet and in a relaxed position. When the tenderness has quite abated, but a swelling and discoloration are left, we may apply friction with the camphor or other liniments, and make pressure by bandages. Sometimes, however, there remains a tumor containing congealed blood, which may be known by its peculiar fluctuation, and which will often not be reabsorbed in spite of all our endeavours. This had better be laid quite open with a bistoury and the blood turned out, and so healed up by granulation. This is particularly to be done when an imperfect supuration takes place in the tumor, forming a bloody pus, which irritates the constitution wonderfully.

CHAP. III.—OF FRACTURES.

Fractures are solutions of continuity in the bony structures, and always the consequence of violence done to the limb; but this need not have been inflicted at the exact spot where the fracture exists, but very frequently (as in the cylindrical bones) at the end of the limb, in which case the weakest part of the bone gives way, which accounts for the frequent occurrence of fracture near the middle of long bones. The flat bones are far less often fractured than the long ones, with the exception of the skull, which, as it produces peculiar symptoms from its affecting the brain, will be noticed particularly hereafter. It is not however to the middle that fractures of the long bones are confined; for their extremities are often found so to suffer, which is always to be regarded as more unfavorable. There are two ways in which a long bone may be broken; viz.

transversely or obliquely. It is more particularly in this last case that the surgeon finds great difficulty in keeping the ends of the bone in opposition, as in all fractures there is a spasmodic action of the muscles, to a greater or less extent, which draws the lower end of the bone over the upper.

A fracture may or may not be complicated with an external communicating wound; if which be present it is called a compound fracture, otherwise it is said to be simple.

SECT. I.—OF SIMPLE FRACTURES.

The symptoms are pain, inability to move the part, with swelling after a longer or shorter period. Crepitus on handling, with an indefinite shortening of the limb (if it be one), together with a deficiency of the bone when the surgeon traces it with his fingers. But where a limb has two bones there will be no shortening if only one has suffered; for the other will act as a splint. In these cases we must trust to the other symptoms, of which the most unequivocal is the crepitus. It often happens that there is deformity of the limb produced, in which case we need no other mark.

Treatment consists in bringing into and keeping the ends of the bone in perfect opposition and quietude; for which purpose Mr. Pott has insisted strongly on the necessity of putting the limb into such a posture that the muscles, which are inserted into the broken end or limb below it, may be relaxed; upon this principle, that when such a severe injury as fracture of bone takes place, the soft parts around are necessarily more or less injured by the ends of the bone, which it is, in fact, that causes the pain. The muscles then, either from being included in the injury, or from sympathy of the nerves which move them, are thrown into a state of spasmodic action, which, in some cases, will last for a long period, constantly shortening the limb, and thus drawing one end of the bone over the other. The position by which this indication can be best answered is one between flexion and extension in most cases. The rest of the local treatment consists in keeping the bones in opposition by means of splints and bandages, interposing a thin soft cushion between the splint and limb, which last had better be supported by a many tailed bandage. If there be much swelling and pain leeches may be applied previously, and the limb may be kept wet with cold lotion even after it is put up in splints. In this manner the limb will unite; if an upper one in about a month, a lower one six weeks, but this may be influenced by circumstances.

Manner of union.—This is effected by a deposit of bony matter called callus, which surrounds the ends of the bones and confines one to the other, and which is formed thus. Mr. Brodie, and afterwards Mr. Mayo, found, on breaking the bones of chickens and rabbits, that in a few days after the injury there was a deposit of coagulable lymph round the broken ends, which after some lapse of time began to contain specks of ossific matter, which gradually shot into each other, and at last became quite bony, enclosing the fractured ends, so that no union is

accomplished till nearly the end of the time, the gradual preparation consuming by far the greatest portion. In recent union, then, the bone is surrounded by an irregular substance, which is gradually absorbed upon using the limb; so that ultimately no such great projection is found. This explanation will account for the union of fractures when put up after a lapse of some weeks after the accident.

Some fractures however do not unite at all, and others not by bone, and in general it is in consequence of insufficient vascularity in the neighbouring textures; of this nature are fractures completely within joints. When those in limbs not in joints do not unite, they will, if left to themselves, form a false joint capable of much motion, which entirely takes away the use of such limb from want of muscles to fix it. When this is the case, or is threatened, we should endeavour to bring on irritation by rubbing the ends of the bones against one another. Besides this several other means have been employed. Mr. C. White recommended, when there is a complete joint formed, cutting down to it and sawing off the ends of the bones, which he practised in several instances and with considerable success; but it has often failed, and in some cases proved fatal. In December, 1802, a new method was proposed by Dr. Physic of Philadelphia, which was the passing of a seton through the limb and between the ends of the bone, and practised by him there and tried since by several eminent surgeons here. It succeeded in many cases, but has failed in nearly as many, which induced Mr. Aymesbury, very lately, to propose a new plan; which was that of keeping the ends of the bone constantly pressed against each other by an immovable apparatus. This has raised considerable expectations, which, as yet, do not seem likely to be disappointed. Sometimes, however, the causes of non union are old age or motion in the fractured limb. In the former case we must allow it to remain a longer time in splints; in the latter our remedy is obvious. Our limits will not admit our entering fully into each particular fracture, but we shall briefly notice a few of the most importance, or which differ in treatment from the general rules.

The *lower jaw* is very difficult to retain in opposition, as the fore portion always sinks from the posterior; for all the muscles of the former running to the os hyoides tend to depress it, whilst the temporalis and masseter elevate the latter. It has been recommended to keep it in position by twisting wire round the molar teeth across the fracture. This keeps the ends from riding, but does not hinder the dropping of one portion. To remedy which we should put a piece of stiff pasteboard under the jaw, and bind the jaws together by a bandage from the head, coming under the chin. The patient must be content to live on liquids, which must be introduced into the mouth through any deficiency of the teeth if there be one, or else the mouth need not be quite closed, but wedged tightly a little way open.

The *vertebrae*, when fractured, cause paralysis of every part whose nerves come off lower than the injury. Respiration is often carried on en-

tirely by the phrenic nerve: they are always fatal at a sooner or later period. When the spine suffers violent concussion it produces symptoms like those of fracture, in a less degree, but by antiphlogistic treatment these generally do well.

Ribs.—These generally happen near the greatest convexity of the bones, several of which are often broken together. The first rib being protected by the clavicle, and the lower ribs being very flexible, are less liable to be fractured than the middle ones. See *Emphysema*.

When a spicula of a fractured rib is beaten inward it may lacerate the pleura, wound the lungs, and cause the dangerous train of symptoms attendant on emphysema.

As a broken rib cannot suffer displacement on account of its anatomical relations, it is often difficult, particularly in fat people, to ascertain it. This may be assisted by making the patient cough, when the crepitus will be more liable to be felt, and he will complain of a pricking sensation; but when there still remains much doubt most surgeons prefer treating it as if fractured.

Treatment consists in preventing any movement of the ribs, and guarding against the occurrence of peripneumony, which is indeed very likely to supervene. The first may be accomplished by rolling the ribs tightly with a flannel bandage, or sewing a piece of linen round the chest; for the latter the strict antiphlogistic means must be used.

Ossa innominata frequently prove fatal from the quantity of injury done to the pelvic viscera. The treatment consists in applying a laced belt round the pelvis, and obviating the effects of inflammation.

Neck of the femur may occur in three places.

1. In the middle of the cervix, or close to the head, always transverse.
2. At the junction with the trochanter major, extending externally; in which case the upper part is sometimes wedged in the lower, as was found by Dessault.
3. Fracture of the trochanter beyond the joint.

Within the ligament.—The symptoms are sometimes very obscure; but Sir Astley Cooper says, 'Under this accident the leg is from one to two inches shorter than the other; the foot and knee are everted. There is little pain when at rest in the recumbent posture. But on rotation a pain is felt, from the rough end of the bone grating against the synovial membranes lining the capsular ligament. The thigh may be perfectly extended, but flexion is more difficult and attended with pain; this is increased if the thigh be directed towards the pubes, and lessened if carried outwards. A crepitus is also discoverable when the limb is drawn down, so as to be of the same length as the opposite one, and then rotated, but not so when the patient is lying on his back with the limb shortened.'

This fracture generally occurs in people of from fifty to eighty years old, and not in young persons; so that a very slight violence is often sufficient to produce the accident.

Treatment.—If there be any doubt it is best to give the patient the chance, and treat it as common fracture. But if this do not succeed then adopt Sir Astley Cooper's method:—

Finding the patient's health suffer from the necessary confinement, what I now direct to be done is that a pillow be placed under the limb, throughout the whole length, and another be put under the knee, and the limb be in this way extended for ten days or a fortnight, until the inflammation has subsided. Then let the patient get out of bed, and sit on a high chair, to prevent being too much bent, afterwards walk with crutches, bearing gently at first on the foot, then increase the pressure more and more, until the ligament becomes thickened and the power of the muscles increased. Next let him use a shoe with a high heel, which would very much diminish his lameness.

The patient treated in this way walks after a day or two with a crutch, then with a stick, and in a few months requires no additional support. This is a fracture which is thought by most never to unite by bone.

Fractures external to the capsule generally occur in younger persons; in these the leg is only from half to three quarters of an inch shorter. The foot and toe are everted, much pain is felt at the hip, and on the inner and upper part of the thigh, and the usual rotundity of the joint is lost; crepitus is easily produced by a slight motion of the limb, and it is not necessary in this accident to draw the leg down to feel the crepitus, as the retraction is not so great as in the former accident. There is also usually great extravasation into the surrounding parts, and this swelling is quickly followed by a great tenderness to the touch; also violent pain is produced upon slight motion of the joint, followed by a high degree of constitutional irritation; and many months elapse before the patient recovers a proper use of the limb. The accident is usually the result of very severe injury.

Treatment consists in pressing the ends of the bone together and extending the limb. The first may be performed by applying a broad leather strap round the pelvis, including the trochanter major; the latter by placing the limb on a double inclined plane.

Fractures through the trochanter major are generally oblique, and may happen without injury to the neck.

These fractures occur at any period of life, and are marked by the following symptoms:—The limb is very little and sometimes not at all shortened; there is a numbness in the foot; the patient cannot turn in bed without assistance, and the attempt is productive of great pain. The trochanter is sometimes drawn forwards towards the ilium, sometimes it falls towards the tuberosity of the ischium, but is generally widely separated from that portion of bone remaining in connexion with the neck. The foot is greatly everted, and the patient cannot sit, as any attempt to do so produces very great pain. You can feel a crepitus with great difficulty, if the detached portion of the trochanter be either much fallen or much drawn forwards.

That for *treatment* is the same as the last fracture.

Fractures into joints cause great swelling and inflammation, and, if not properly attended to, often produce ankylosis.

Treatment consists in abating the inflammation at first, then applying a pasteboard splint; but after four or five weeks we should commence a gradual motion of the joint to prevent ankylosis.

Patella is very often caused by violent spasm of the extensor muscles; as when a person endeavours to prevent his falling after tripping. In treating them we must relax the muscles attached to it, by extending the limb on a plane inclined upwards, and bending the body on the thigh; then bring the bones together by bandages or straps.

Clavicle is generally treated by placing a pad under the axilla, and then applying one bandage round the shoulders and armpits, behind the back in the form of the figure 8, and another supporting the arm from the front, going from the bent elbow to the opposite shoulder.

SECT. II.—OF COMPOUND FRACTURES.

These differ from simple in having an external wound communicating with the fracture, which makes a great difference in symptoms, treatment, and process of healing. If the wound be not very large, and be caused by the ends of the bone, or any sharp instrument, we should merely put a piece of lint over, and it will most likely heal, thus at once converting it into a case of simple fracture.

But there are other complications which render the management truly critical, and call forth all the powers and skill of the surgeon, and in nothing more so than the important question of when it is necessary at once to deprive the patient of his limb; or when the surgeon, having duly considered and weighed all his reasons for and against it, determines to try and save it, at the greater hazard of his patient's life: but, before considering this, it will be better to explain the mode of union and symptoms of compound fractures.

When the wound of a compound fracture does not unite, then a suppuration must come on, attended with more or less disturbance of the constitution; then, if the patient have been of robust health and no bad symptoms intervene, the discharge of pus is gradually abated; granulations arise from the surface of the abscess, which surround the bone; these are gradually converted into cartilage, in which ossific deposits take place; and thus the bones are united, the granulations fill up the external wound, and the patient recovers. But if the accident be severe, and the patient's health not able to bear the shock, the wound inflames, puts on an erysipelatous appearance, matter burrows amongst the muscles, forming considerable lodgments, attended by hectic fever in its worst form, the discharge is profuse and fetid, and, the powers of the patient being unable to sustain all this, he sinks and dies. Or the case may be still worse; for gangrene may seize the affected limb, in which case amputation is his only chance of escape.

Cases in which amputation is necessary. These are not so easily reduced to rule now as formerly, when the surgeons enumerated a list of cases in which this operation was to be performed at once.

But, if any cases seem to demand it more than

others, it must be when the injury to the soft parts is extensive, or when a large joint is lacerated and fractured. Formerly it was held as a maxim that when a large artery was wounded, with a compound fracture, the limb must mortify. But Sir A. Cooper recommends tying the artery at the wound if possible, or, if not, taking it up higher in the limb, and giving the patient his chance of recovery, which he has seen take place in several instances. In old people, who cannot sustain a suppuratory process, it is fit to amputate. As to amputating the limb afterwards, we must be guided by our own judgment, and, if we find the patient sinking, perform the operation.

Treatment of compound fracture.—Our first step must be to reduce the bones, which are often found protruding. If we cannot do this without a great deal of violence, we had better enlarge the external wound. If, however, the fracture be very oblique, sawing off the ends is preferable. If there are many splinters of bone they must be removed. Sometimes, in spite of all the surgeon can do, there are violent spasms of the muscles, in which case we must amputate. The rest of the treatment consists in keeping the parts immoveable by an eighteen tailed bandage, and splints or fracture boxes, dressing the wound lightly, and treating the constitutional symptoms as they arise; but above all endeavouring to heal the wound.

SECT. III.—OF DISLOCATIONS.

These consist of a separation of the articulating surfaces of bone from one another, and may be divided, like fractures, into simple, when there is no communicating wound; and compound, when such complication is present. They may also be combined with fracture, as at the ankle, where the fibula is mostly broken. A dislocation is said to be partial when it is not entirely separated from its articulation. These injuries are commonly the result of violence, but may arise independent of direct force, as in ulceration of the cartilages of the hip joint, where the head of the femur is drawn by the muscles into the dorsum of the ilium; or, in dislocation of the patella, from too much distension of the knee joint by synovia.

Symptoms are an alteration in the length of the limb, as also in its axis. It becomes unnaturally fixed, capable of being only slightly moved by another person, painful and swelled, the appearance of the joint much altered from that of its fellow. There is also sometimes a crackling to be felt on motion, that may be mistaken for the crepitus of fracture; but the former is caused merely by the escape of synovia into the surrounding cellular membrane, becoming thicker by absorption. It is obvious that in dislocations, the neighbouring parts must suffer considerable injury by the pressure of the head of the bone; and it is remarkable that, if a limb or joint be left unreduced, a condensation of the parts around happens, and a new synovial membrane is formed, whilst a cavity is at the same time prepared to receive the dislocated end by the bone on which it rests.

Treatment should be to reduce the dislocation to its natural position, which in most cases is

to be performed by making extension of the dislocated limb, having previously either fixed the limb above, or else making counter-extension at the same time. This may be undertaken by manual aid in recent cases; but, when long-continued force is required, it will be better to use pulleys as counter-extensors. The obstacles to reduction are—

1. The muscular power of the patient, constantly, though involuntarily exerted in opposition to the surgeon. These, then, it should be our fixed endeavour to relax, by attending to the position of the limb, and if that fail, by bleeding and nauseating the patient; for now, when the strength is exhausted, the muscles can be readily overcome by constant but gradual extension. This was the great doctrine laid down by Mr. Pott, which, before his time, was not sufficiently attended to.

2. Difficulties in reduction, likewise arise from the head of the bone catching against the articulating cavity. As in the dislocation of the thigh bone into the foramen ovale, and ischiatic notch, where it is necessary to raise the head before it can be returned; or where the head of the bone is larger than its cervix, as in dislocations of the radius.

3. The peculiar ligaments of the joints sometimes prevent the reduction of dislocations. This is particularly to be noticed in the knee, where the bone should be moved in such a direction as to relieve that ligament which remains entire. The ligaments of the ankle joint are of extraordinary strength, and the bones of this joint will often rather break than their ligaments give way.

4. Length of time elapsed is another impediment; for, after a lapse of time, the bone is retained in its new position by adhesion.

After we have succeeded in reducing dislocations, we must keep the limb bandaged, perfectly immoveable, and subdue the inflammation of the joint, which will in all probability supervene. Then, after a short period allow the patient to exercise his limb by degrees.

Compound dislocations.—Having previously noticed that any wound of a joint was dangerous, it would be almost fruitless to expatiate on the increased risk when a joint is not only wounded, but forcibly torn open or lacerated with displacement of the articulating ends. In such cases, then, all the nice discernment of the surgeon is again (as in compound fracture) called into activity. The degree of violence and laceration done to the soft parts, the great or little chance of healing the wound by the first intention, and the youth or advanced age of the patient, are circumstances which ought to influence the judgment in this difficult part of surgery. In the country, also, many cases would recover, which in town would not do so, without amputation.

Treatment consists in reducing the dislocated bones with as little violence as possible; and if one end is found projecting, and cannot be managed without force, it is better to saw it off than offer such violence to the already ruptured ligaments as its reduction must occasion. The rest of the treatment to be adopted is the keeping the parts perfectly motionless, so giving the torn li-

gament, an opportunity of healing, and endeavouring as soon as possible to close the external wound. The symptoms of inflammation must then be treated as they arise; and, if suppuration take place, we must follow the rules already laid down.

Particular dislocations are of the lower jaw, and may be caused by violent gaping or yawning, particularly by a blow on the chin while in the latter act.

Symptoms.—When the jaw is completely dislocated, both its condyles are advanced into the space between the surface of the temporal bone and zygomatic arch. The jaw is known to be completely dislocated, by the mouth being opened, and the patient not being able to shut it by any pressure which you may make on the chin. The lower teeth will be found in a line anterior to the upper. You may depress the jaw a little, but to a very inconsiderable extent. The appearance is just that of a person when yawning. The pain, though severe, is not attended with danger. The saliva is very much increased in quantity, in consequence of the irritation of the parotid glands, and it dribbles over the mouth; or the dislocation may be only of one side, in which case the symptoms will be present only on that side, giving the jaw a ludicrous twisted appearance.

Treatment.—They are generally reduced by wrapping a handkerchief around the thumbs; placing them on the corionoid processes, and depressing the jaw, you force it backwards as well as downwards, and the bone suddenly slips into its place. But if it be of longer duration we should place two corks behind the molar teeth, and then, keeping these for fulcra, elevate the jaw.

Clavicle.—Sternal end. This may be dislocated in two ways, forward and backward. The latter is very uncommon, and generally the result of distorted spine, consequently nearly irremediable. The former, however, is more common, and may be readily distinguished by the swelling over the sternum and sensation to the fingers.

Treatment.—We need only apply the figure of 8 bandage, without supporting the arm.

Clavicular end.—This dislocation may be detected by putting the finger on the spine of the scapula, and tracing it forwards towards the acromion, where the finger will be stopped by the projecting portion of the clavicle. The shoulder will be depressed and drawn inwards towards the sternum, and from the projection of the clavicle it will appear flattened, something like the dislocation into the axilla.

Treatment.—Let the knee be put between the patient's shoulders, and draw them backwards and upwards, and the clavicle immediately is brought into its place; then put a thick cushion into each axilla, to keep the scapula from the side, to raise it, and to prevent the axilla from being injured by the bandages. Then the clavicle bandage is to be applied, and its straps should be broad enough to press upon the clavicle and scapula. The arm should be supported in a short sling, so as to keep the scapula well up.

The *humerus* may be dislocated in four directions. 1. Downwards, into the axilla, resting on the inner edge of the inferior costa of the scapula.

In which case there is a projection of the acromion, natural rotundity of the shoulder lost by a flattening of the deltoid muscle, which is dragged with the head of the bone; downwards the elbow is always projected from the side and semiflexed.

Treatment.—Fix the scapula well by one bandage, or long towel, held by assistants, passing above the acromion down to the opposite side, and another passing under the scapula up to the opposite side; then, raising the arm to a right angle, make gradual extension, by fastening a towel round it by what is called a clove hitch, and which will not slip; making, at the same time, a slight rotatory motion which relaxes the muscles. When the extension has been made sufficiently long, the surgeon may elevate the head of the bone by any handy means, and it will slip into its natural cavity. The shoulder should then be bandaged by a figure of 8, and the arm confined to the body. If a surgeon have no assistant at hand he may make the patient lie down and extend the arm, fixing his heel in the axilla, for the counter-extension; and this often succeeds in recent cases.

2. Forwards under the pectoral muscle and upon the second rib, when the projection of the acromion is very great. Depression of the deltoid more considerable. There is more pain; and the prominence of the head of the bone may be felt and seen beneath the clavicle. The elbow is thrown from the side and backwards.

Treatment.—The extension must first be made obliquely downwards and backwards, until the head of the bone has passed the coracoid process; then it may be raised in an horizontal direction, and, by the pressure of the heel in the axilla, the bone will be easily returned.

3. Backwards on the dorsum of the scapula, just beneath the spine. This may be known by the projection of the head of the bone. The reduction is the same as for that in the axilla; but the head should be rotated inwards.

A *partial dislocation* is a very frequent accident. In this dislocation, the head of the bone is thrown forwards against the coracoid process; there is a hollow at the back part of the shoulder joint; the axis of the arm is thrown inwards and forwards; the under motions of the arm are still performed, but it cannot be raised, from its striking against the coracoid process. The head of the bone may be felt to rotate.

The reduction of this dislocation is the same as that for the dislocation forwards: but the shoulders should also be drawn backwards, to bring the head of the bone to the glenoid cavity. After the reduction the shoulders must be secured by the clavicular bandage, or the bone will again slip forwards, against the coracoid process.

There are several accidents which are liable to be mistaken for dislocations of the humerus. These are, 1. Fracture of the acromion; in which the shoulder loses its roundness and the head of the bone drops towards the axilla; but the joint recovers its shape on elevating the head of the bone. There is also a crepitus on raising and rotating the elbow.

Treatment.—Elevate the fractured piece of bone by the head of the os humeri, placing a pad between the elbow and side; support the elbow

in a tight sling, placing the forearm across the chest, and preventing all motion by binding the humerus to the side.

2. Fracture through the neck of the scapula is more likely to be mistaken for dislocation than any other; but by carrying the hand over the shoulder, and resting the finger on the caracoid process, and then rotating the arm, a crepitus will be felt. Again, place your arm under the arm of the patient, and, by raising it a little, you will restore the natural appearance of the joint; but, when you take away your support, the shoulder will again sink.

The *treatment* of this fracture is to place a thick pad in the axilla, to carry the humerus, and with it the glenoid cavity, outwards; to support the humerus in a short sling, to preserve the parts in apposition. The clavicular bandage will assist in keeping the head of the bone outwards, and the motion of the arm may be prevented, by confining it to the chest by a roller. It requires from ten to twelve weeks for its recovery, and continues weak for three weeks after.

3. Fracture through the neck of the humerus, may be distinguished from dislocation in the same manner as the accident just mentioned, and by passing the hand over the shoulder-joint, and fixing the head of the humerus with the fingers, whilst at the same time having raised the elbow, and carried the upper part of the humerus a little outwards, you will feel a crepitus on rotating the elbow, but the head of the bone does not follow the rotation of the arm. In this accident you are to apply a roller, from the elbow to the shoulder joint, and put a splint on the inner and outer side of the arm, to be confined by another roller; a thick pad is to be placed in the axilla, and the arm gently supported in a sling. The principal difficulty is to prevent the pectoral muscle drawing the body of the bone forwards; but, if the inner splint be properly applied, its influence will be counteracted. It requires from three to six weeks to unite, according to the age of the patient.

Dislocations of the hip.—1. And most frequent. Upwards and backwards on the dorsum of the ilium.

Symptoms.—The limb is from one inch and a-half to two inches and a half shorter than the other. The toes are turned inwards and rest on the tarsus of the other foot. The knee a little advanced on the other; abduction of the limb is prevented; but adduction is still practicable to a small extent. This accident may be confounded with fracture of the thigh bone, within the capsular ligament, but is known by the toes turning inwards, not outwards, as in the latter.

The amputation at the hip joint has been so often performed with success that it may now be considered as one of the established operations of surgery; but, for my own part, I do not consider it should be done when you can saw through the trochanter major. When the acetabulum is laid open, great constitutional irritation is produced by the suppurative process; abscess after abscess arises, and the life of the patient is put into imminent danger; whereas the amputation through the trochanter major is attended with very little risk.

Treatment.—Extension must be made by assistants or pulleys (the latter are generally necessary), and at the same time counter-extension, by passing some strong girt between his thighs round the pelvis, which must be well secured. Then, when the head is brought nearly to a level with the acetabulum, we should rotate the bone and it will slip into its place; but we must not expect in this case to hear the sudden snap, as the muscles are previously so much exhausted as to be unable to act spasmodically. This, however, is not all that is necessary. For, unless the subject be naturally weak, we must begin the treatment by bleeding and nauseating to reduce the muscular power.

2. Downwards into the thyroic foramen.

Symptoms.—The dislocated limb, in this case, is two inches longer than the other. By making pressure with the hand on the upper and inner part of the thigh, you can, in thin persons, distinctly feel the head of the thigh bone. There is a flattening of the hip on that side; the body is bent forwards, owing to the psoas magnus and iliacus internus being put upon the stretch. If you desire the patient to stand upright, you find that the knee is considerably advanced towards the trunk. It is widely separated from the other knee, and it cannot be brought to touch it without much difficulty and pain. The foot is generally turned outwards or inwards, but the toes point to the ground.

Treatment.—If the accident be recent, place the patient on his back, separate the thighs as widely as possible, and place a girt between the pudendum and upper part of the thigh; fix the girt to the staple in the wall, then take hold of the ancle of the dislocated side, and draw it over the other leg, or, if the thigh be very large, behind the sound limb, and the head of the bone usually slips into the socket.

When of longer standing, in these cases, it is better to place the patient on his sound side, and fix the pelvis by one bandage, and carry another under the dislocated thigh, to which the pulleys are to be affixed perpendicularly; then draw the thigh upwards, and, at the same time, press down the knee and foot, to prevent the lower part of the limb being carried with the thigh, and you thus use the limb as a lever of considerable power. But take care not to advance the leg too much, as the head of the bone will be forced behind the acetabulum into the ischiatic notch, from which it would be extremely difficult to remove it.

3. Backwards, into the ischiatic notch, is the most difficult of all the dislocations of the thigh to detect, because the length of the limb differs but little, and its position is not so much changed, as respects the knee and foot, as in the dislocation upwards.

In this dislocation the head of the bone is placed on the pyriformis muscle, between the edge of the upper part of the notch and the sacro-sciatic ligaments. The limb is from half an inch to an inch shorter than the other, but usually not more than half an inch, and the toe rests against the ball of the great toe of the opposite foot. The natural prominence formed by the trochanter major is lost, but it still remains

clearly at right angles to the dorsum, but it has a slight inclination towards the acetabulum. Except in very thin persons, you cannot feel the head of the bone, and then only by rolling it a little forwards. The knee and foot are turned inwards, but less so than in the dislocation upwards: the knee is only very slightly bent, and therefore is not so much advanced as in that dislocation. The toe touches the ground when the patient is standing, but not so the heel. Flexion and rotation are in a great degree prevented from the limb being so firmly fixed.

Treatment.—Lay the patient on his side; make extension and counter extension; and, at the same time, lift the thigh outwards by a bandage placed as near the head of the bone as possible.

4. *Dislocation in the pubes* is the most easily distinguished of any.

Symptoms.—The limb is an inch shorter; knee and foot turned outwards, incapable of rotation inwards, and the head of the bone may be felt on the pubis, outside the inguinal artery.

Treatment.—Place the patient on his side; make extension and counter extension; and, after a little time, lift the head of the bone forwards over the pecten and acetabulum.

Pott's dislocation or fracture is a dislocation inwards of the ankle joint, attended with fracture of the fibula, about three inches higher up, and laceration of the internal or deltoid ligament. This is a very serious injury; often causing permanent lameness. It is to be reduced as soon as possible, and protected by splints or junks. The limbs should be bent to relax the muscles, and the leg laid on its outside.

Rupture of tendo Achillis happens mostly in persons advanced in life, and usually upon making some sudden or unusual exertion. It has been known to happen to old men when, after a lapse of years, they attempt to dance. The symptoms by which it may be known are these:—The patient, whilst making this exertion, feels as if struck with a whip or stone at the back of his leg, and often hears a loud crack, and falls down from inability to use his foot. The gastrocnemii muscles act spasmodically and pull the upper away from the lower portion, which can readily be felt on examination.

Treatment.—Formerly the patient was laid up, and the foot kept extended for four or five weeks; but surgeons are now content to let them wear a very high heeled shoe, and hobble about with sticks, till it is well.

Sprains are caused by forcing a joint in any direction beyond what the ligaments will allow; consequently these latter are more or less put on the stretch or ruptured, depending on the relative degree of violence offered. They are always attended with pain and swelling, and the motions of the joint very much impaired. They are most frequently met with in the wrist and ankle.

Treatment.—If the inflammation and pain be excessive, leeches must be applied; when, however, they are only moderate, we may be content with applying cold to the part and keeping it perfectly quiet; and, when the violence of the symptoms has abated, we should support the parts by adhesive straps and rollers, which will be found very much to assist motion.

CHAP. IV.—OF INJURIES OF THE HEAD.

Mr. Pott has remarked that the scalp cannot be considered in the light of a common integument; for, from its intimate connexion with the skull and brain, it deserves particular notice. When any part of it is cut we may treat it as a simple wound. But when it is lacerated by a stroke of a stick, or any instrument which must have been applied with some violence, we then no longer consider the mere wound as the grand object of our treatment, but keep a strict watch for the symptoms which may arise of injury within the head.

Contused or lacerated wounds of the scalp should be treated like other wounds, but we should not be too anxious to heal them quickly at one part, leaving another to suppurate; by which a collection of matter may take place, pressing on the bone, and often lifting the pericranium from it, in which case there is always a tendency in the dura mater (which acts as an internal pericranium), to separate also, thus entirely depriving a portion of bone of its nourishment, so that it dies and exfoliates. It is the duty of the surgeon then to open all collections of pus in the scalp as soon as possible. When the scalp is much lacerated and jagged, the surgeon should avoid cutting off the irregular portions, as they have always a chance of living, and so covering the skull, and, if they slough, it will then be time enough to remove them; but exposure of the skull is always to be avoided. When the scalp has been bruised there frequently takes place an effusion of fibrine and serum, making a swelling, which, on pressure, allows the finger to sink a little way, but then gives the sensation of a distinct acute edge, and so may be mistaken for a fracture of the skull with a piece of bone driven in. It may be known by its want of symptoms of depression, or by the acute edge also subsiding on pressure. An erysipelatous inflammation, says Mr. Pott, is very liable to occur after scalp wounds, which, though alarming in appearance, is not so dangerous in reality; it occurs generally in bilious subjects, and is to be treated by bleedings, saline purges, and cold lotions.

There are three sorts of accidents that affect the head; 1. Blows without symptoms of concussion; 2. With symptoms of concussion at the time of the injury; 3. Compression of the brain.

SECT I.—OF BLOWS WITHOUT SYMPTOMS OF CONCUSSION.

It is to Mr. Pott that the profession owes the earliest account of the first injury, viz. a person receives a blow on the skull which may or may not produce a wound; he is a little stunned at the time, but it goes off in a moment, and he thinks no more of it. In a few days he returns to his medical attendant, having had one or more shiverings, with nausea, pain, at first confined to the spot, afterwards extending over the head, languor, restlessness, quick and hard pulse, and a flushed face, a puffy tumor, tender, but not painful, arises on the stricken part. If this were cut into and examined, the pericranium would be found either partially or totally separated

from the bone, and containing a small quantity of black colored ichor. The color of the bone also is found altered. From this time the symptoms advance more rapidly, the fever increases, the pulse becomes quicker, the skin hotter, the sleep more disturbed, and the shiverings more frequent, not followed by perspiration. It is now that matter becomes smeared over the dura mater, and after this the symptoms are exasperated every hour, convulsive motions come on, attended, in some, by delirium, in others by paralysis, coma, and death. If there had been a wound of the scalp, in this case, it would also have sympathised, and become pale, glassy, and flabby.

Treatment.—If called to the patient early, our endeavour should be to hinder suppuration; and for this purpose we should bleed, and use strict antiphlogistic regimen, especially keeping the patient quiet; but, if we find by the symptoms that matter has formed between the skull and dura mater, we cannot let it out too soon, by perforating the bone with a trephine (of which hereafter), and the place where it should be applied will be indicated by the puffy tumor. If the collection is found extensive, and the symptoms do not yield to one perforation, we must remove another portion of skull. In our after treatment, we must guard against increased inflammation of the dura mater, using the most powerful antiphlogistics, of which bleeding and cold applications will be found most serviceable. The cause of all this mischief seems to be a laceration of the fine vessels, running from the dura mater and pericranium into the bone, by the vibration of the blow, so that a trifling inflammation is set up, which, from the susceptibility of the parts concerned, soon becomes aggravated, and gives rise to the above-mentioned symptoms.

SECT II.—OF CONCUSSION OF THE BRAIN.

To produce this, a greater degree of violence must have been offered, and in this case, as in the former, there may or not be a wound of the scalp. The symptoms are these: the person who receives such injury, is at once deprived of sensation and motion, but which return in some measure almost immediately, and the surgeon finds him lying down, apparently insensible, but he is capable of being aroused, and giving coherent though peevish answers, relapsing immediately into his former state; his face is pale, the pulse, not much hurried at first, but very weak and thin, and sometimes even intermitting; he generally vomits in a few minutes after the accident, which the surgeon considers as a sign of nonexistence of compression; the pupil is also capable of motion, when exposed to a strong light. If the case is favorable, these symptoms gradually subside, and the patient thinks himself cured; but the well informed surgeon, knowing the liability of the occurrence of secondary inflammation, keeps a watchful eye over him for several days, enforcing a light diet, and perfect quiet.

There are two great dangers to be apprehended in cases of mere concussion: One is the occurrence of hemorrhage within the skull in a short time after the injury, and upon the establishment

of re-action; for not only may very small vessels be lacerated by the severe shock, but some of great size, and particularly the middle artery of the dura mater, which does not bleed whilst the patient lies in that state of syncope into which he is at first thrown; but, when the heart resumes its strong action, the blood is propelled from this vessel into the surface of the brain, causing gradual symptoms of compression. The other great danger is the supervention of inflammation of the meninges of the brain. This occurs at various times, but commonly in three or four days after the accident. The symptoms of this inflammation differ from idiopathic inflammation of the brain, the fever being of a much lower type; the face is a little flushed, the eye particularly sensible to light intolerance of noise; pain in the head, particularly in the forehead; much restlessness, and muttering delirium; the pulse is quick but not so full as in idiopathic phrenitis. If these symptoms cannot be checked, suppuration will supervene, causing compression. It is marked by an attack of shivering delirium, ptosis of the upper eyelid, convulsions, and death.

Treatment.—In the first instance the powers of the patient are very much depressed; whilst he is in this state the surgeon need not interfere; but, as soon as the pulse rises, he should be bled largely for two reasons; one, to prevent internal hemorrhage: the other, to render the supervention of inflammation less probable. If the headache continue, with restlessness, &c., we should repeat the bleeding, preferring small quantities, taken oftener, to large ones at once, giving free purgatives and diaphoretics; and, if symptoms of inflammation come on, we should shave the head, and apply bladders filled with ice to the scalp, and repeat our large bleedings, with other remedies for inflammation. If symptoms of compression supervene, either from hemorrhage or pus effused, we should trephine the part where the puffy tumor exists; or, if there be none, we must then choose the point where the violence was inflicted. If the suppuration has occurred between the dura mater and bone this may be successful; but it too frequently occurs between the dura mater and arachnoid, in which case it is out of the reach of art.

SECT. III.—OF COMPRESSION OF THE BRAIN.

We have already noticed cases in which this may arise, but it is caused most frequently by a fracture and depression of a portion of the skull. Its symptoms are a total state of stupor, stentorous breathing, immobility of the pupil (which is nearly always dilated) when irritated by light, face tinged, pulse slow, full, and laboring, convulsions or paralysis, retention of urine, and constipation of the bowels, or else involuntary discharges from the bladder and rectum; and these symptoms do not abate but increase.

Treatment.—When a piece of the skull is fractured and driven in, it must be removed by the operation of trephining, which is to be performed in the following manner:—The integuments are to be divided by a crucial incision, to give freedom to the operation, provided there be not a sufficiently large wound of the scalp; and

now the surgeon can examine the injury; if there be comminution of bone, the pieces may sometimes be taken away by forceps and elevators, but if a piece is wedged in, we must then remove a sound piece by the trephine to get at the depressed portion; the operator then (without tearing, rasping, or scraping, the pericranium, as was recommended formerly) fixes his trephine in the sound bone, and makes several turns. Having now established a groove for the free play of the teeth, he withdraws the central point, which being projected would otherwise pierce the bone earlier than the sawing part, and so wound the dura mater, the endeavour to avoid which must regulate every movement of the operator, who now proceeds slowly and cautiously, withdrawing the trephine at short intervals; to find out by probing (for which purpose a piece of quill is generally used), whether or not he has perforated any part of the circle; for the thickness of the skull, varies considerably both generally and in small spots, so that it is very common, even in the small bit enclosed by a trephine, to find three or four different degrees of thickness. When he finds the instrument has penetrated one part, he must remove all farther pressure at that point by an inclination of his hand and wrist, still sawing the part not yet accomplished; when he finds that his task is nearly finished, he need not wait for the division of every little portion, but, having found no further resistance to his probe at several points, introduces an elevation or forceps into the sawed fissure, and forcibly breaks up the circular bit, which, being now accomplished, leaves him at liberty to elevate the depressed portion; but it is sometimes necessary to take out another piece by the trephine before he can accomplish it: or an obstruction may be caused by a projecting piece of the skull, which will be found to be more easily removed by the saw recommended by Mr. Hey of Leeds.

When the operation is concluded, the wound is to be dressed with lint dipped in oil, coming to a level with the skull, and the integuments brought over it; or if the opening has been made to let out congealed blood; or at other times, when the termination of the case is clear, the scalp may be brought at once over the dura mater, and confined by sutures, leaving a depending opening for the escape of pus, which must form in order that the wound may granulate, which it does from the surface of the dura mater. It was formerly supposed that all fractures of the skull required this treatment, whether there were depression or not. But modern surgeons, following the advice of Dessault, John Bell, and Abernethy, totally disregard the presence of a mere fissure, and shape their treatment entirely by the symptoms: so that if those be only of concussion, and the skull be fractured, or even slightly depressed, the case is merely to be treated as a severe one of concussion.

There was also great stress laid formerly on the parts of the skull which we should not trephine; such as the part over the frontal sinuses; longitudinal sinus over the middle artery of the dura mater, &c. But surgeons now find they can, by using caution and care, trephine in even

these parts. For if there be hæmorrhage from the artery, or sinus, they may be stopped by moderate pressure, or the artery tied.

It is to be noticed that fissures often run for a considerable extent beyond the part where the injury was inflicted, causing perhaps extravasation in their whole course. Thus, the forehead being struck, a fissure is often found quite across the orbital plate of the os frontis; and in violent falls on the top of the head, or injuries of the temple, fissures run along the base of the brain; in either case they are mostly fatal.

There yet remains one source of mischief from wounds of the head and skull: fungus cerebri. This arises when the dura mater becomes ulcerated or sloughy, either from wounds, or as a consequence of the operation, not having been then indeed wounded; but the pulsation of the brain pressing it continually against the sharp edge of bone left by the trephine. This disease should be attempted to be subdued by pressure and mild stimuli; but there have been instances of its being cut off without proving fatal.

CHAP. V.—OF HERNIA.

Hernia, *ερνος*, gerinen-ramus, from its shooting forward, though applicable to all protrusions of viscera, has yet been appropriated to those of the abdomen, from their greater frequency. Of these there are three principal varieties, viz. the inguinal, femoral, and umbilical. Their causes seem to be a sudden straining of the diaphragm and abdominal muscles, as in some sudden exertion, which violently thrusts out some viscus.

1. Inguinal hernia presents itself at the groin, at the external abdominal ring, sometimes descending into the scrotum of males, or labium pudendi of females. It is much more common in males. Its symptoms are, a hard tumor in the groin following the course of the spermatic chord, and descending into the scrotum; suddenly augmented on coughing; capable of being returned into the abdomen when the patient is recumbent, with a gurgling noise, and again appearing on his resuming the erect posture. It is not transparent, and the testicle can generally be felt distinctly below the tumor. This hernia may or not be contained in a bag of peritoneum, which it pushes before it; in the latter case it is called a congenital hernia, from its occurrence at the time of birth, or very soon after, before the opening from the abdomen into the tunica vaginalis is closed, and so is in contact with the testicle.

SECT. I.—TREATMENT OF REDUCIBLE HERNIA

In the common inguinal hernia the patient should, after reduction, apply a truss, which, if the patient be old, must be worn for life; if young, the complaint may be cured in three or four years, by producing obliteration of the opening through which it protrudes. The danger to be apprehended in all hernia is that the gut, or omentum contained in them, may become strangulated, which, if not relieved by art, will prove fatal. In congenital hernia, we cannot apply a truss on such young children on account of its inconvenience; it is better, therefore, to put a compress over the opening, and strips of

sticking plaster round the pelvis to retain it, and it may, by changing the dressing every week, be generally cured in three or four months. But there is one caution necessary in this case: it is that the testicle may not have descended; so that in this case we must not obliterate its passage, but wait till it appears, and then commence our treatment. This caution will sometimes be found necessary, even in adults.

2. Femoral hernia appears under Poupart's ligament at the femoral ring; has a sac like the first species, and is more common in women. It is likewise more liable to strangulation, though generally of small size. But this last circumstance has been noticed by Sir A. Cooper to predispose to strangulation, as it argues a less capacity in the opening. Its treatment does not differ from that of inguinal hernia, except that the pad must be more at right angles with the truss.

3. Umbilical hernia presents itself, as its name implies, at the umbilicus, and does not differ from the others in its mode of treatment.

SECT. II.—IRREDUCIBLE HERNIA.

Hernia not congenital often contains omentum as well as intestine, which is a frequent cause of their becoming irreducible, either by growing into a solid fatty substance, too large to be returned, or by forming adhesions to the peritoneal sac, which last may happen to either intestine or omentum. When a hernia becomes irreducible, it has always a tendency to grow larger, so that in some old men scrotal hernia have contained the bulk of the intestines.

Treatment.—The patient should wear a truss with a hollow pad, with a spring not strong enough to give pain; but in very large scrotal hernia a suspensory bandage, fastened round the loins or neck, will be found to answer better. A person with irreducible hernia should be always on his guard against strangulation, and so should avoid all violent exercise, and be particularly careful to guard the tumor from blows, or other injuries, and attend to the keeping up a free action of the alimentary canal.

SECT. III.—STRANGULATED HERNIA.

This name is applied when either after the sudden appearance of a hernia, or from extraneous cause, in an old one, the patient finds himself unable to reduce it; has an obstinate costiveness, pain, and redness in the tumor, with vomiting, gradually becoming more severe, at last bilious or feculent; pain being felt also in the abdomen, especially about the umbilicus; the pulse weak, frequent, and thready, with hiccup and anxious countenance; and, if not relieved, cold sweats come on. The hiccup becomes more severe, the eyes glassy, pulse softer and fuller, but intermitting; a sudden cessation of pain ensues: the tumor becoming of a dull leaden color and mephysematous. In short the tumor has mortified, and the patient, deceived by the cessation of pain, often fancies that he is about to get better, whilst he is expiring.

These symptoms are caused by the circulation of the contents of the hernial tumor being stopped, either by a thickening of the neck of the sac, a spasm of the abdominal muscles causing a stric-

ture at the point of exit; an extra portion of intestine or omentum wedging itself in the point of exit; or an augmentation of bulk in the part already descended, particularly an inflammatory affection of that part.

Treatment.—The first remedy which suggests itself to the surgeon is the operation of the taxis, or an attempt by manipulation to return the hernia into the abdomen. For this purpose, the muscles near or affecting the part must be relaxed by position; and the surgeon gently lays hold of the tumor, and does not attempt to return it by pushing it straight back, but rather pulls it downwards, at the same time pressing it to expel its contents, and, when successful, a portion of the air contained in the intestine escapes through the stricture with a gurgling noise, which is followed slowly by the hernia itself. In using this means of cure, we should avoid using too much violence, as instances of the tumor bursting have been known.

If the tumor is so much inflamed as not to bear the taxis, and the symptoms are not urgent, cold should be applied for some time. If we fail in our attempt at reduction, after using the taxis for a quarter of an hour or twenty minutes, the patient should be bled largely, or to syncope, being previously placed in a warm bath, which materially assists the supervention of syncope; and now, whilst he is in that state, with every fibre of the body relaxed, we should renew our taxis, and it often succeeds; if it does not, we should give a tobacco glyster, infusing one drachm of tobacco in a pint of boiling water for a quarter of an hour, of which it is best to give only one-third at once, as it produces different effects in people. It makes the pulse small, the skin cold and pallid, and relaxes the fibres generally, particularly muscular ones; so that it succeeds oftener in hernia near muscles, as inguinal or umbilical, than in the femoral. If, after waiting a short time and again trying the taxis, the symptoms become urgent, we must proceed at once to the operation; and, as this is a little different in each hernia, we must describe each separately.

SECT. IV.—OPERATIONS FOR HERNIA.

1. *Bubonocoele or inguinal hernia.*—The patient should be laid on a table with his legs hanging over the end, and, the hair having been removed from the pubes, the incision should commence at the upper part of the tumor, and be continued to its lower part; but, if large, it need not quite reach so low. We should now secure any bleeding vessels. The division of the skin brings the fascia of the chord into view, which must be carefully lifted up with a pair of dissecting forceps, and perforated into this opening; a director must be introduced, and the fascia may be safely slit up, bringing the cumastic muscle into view, which must be treated like the last fascia; and we shall now in recent hernia come to the sac, of a blue semitransparent appearance (but in old hernia there may be many layers of condensed cellular membrane). This must be carefully divided, being previously lifted up, as the others were, and on puncturing it fluid generally escapes, if there be intestine in it not adherent. If there be both omentum and intestine, the for-

mer is before the latter behind, and now commences the difficulty. You must ascertain the seat of the stricture, and in recent hernia it will be likely to be at the external ring. This is to be ascertained by the little finger, and if it be there a director is to be introduced and the stricture divided, for a small distance, by a probe pointed bistoury. But this is not the common seat of stricture; it is generally at the internal ring or neck of the sac, in which case Sir A. Cooper recommended dividing the stricture leaving the sac entire; but this has been justly condemned by Mr. Lawrence in his valuable treatise on Hernia, who prefers the old method of dividing both sac and stricture at once; in this manner introduce the finger as far as the stricture, and on it the bistoury invented by Sir A. Cooper, which is quite straight and blunt, except half an inch, situated at a quarter of an inch from the top which has a cutting edge. This is to be kept flat till it reaches the stricture, but we then turn its cutting edge upwards and divide both sac and stricture. We must beware of cutting inwards, as we then run a great risk of wounding the epigastric artery, which is contained in the inner pillar of the internal ring. The stricture having been freely divided, we reduce the intestine first piece-meal, handling it carefully and tenderly, and then the omentum, if there be any. But the intestine is sometimes found to have formed adhesions. These, if slight, may be torn with the fingers, but, when more dense, they must be separated from the sac by cutting; and, if they are very short, we must cut off small portions of the adherent sac and return altogether in the abdomen. But sometimes the intestine will be found gangrenous, when it will be found of a deep brown or chocolate color, covered with a layer of brown coagulated lymph, fetid, and interspersed with purple or leaden-colored spots, which readily break down under the impression of the finger. It only a portion of the cylinder be gangrenous, we need not, says Mr. Lawrence, put a ligature round the attached mesentery to keep it to the mouth of the sac, for its natural adhesions, which it has formed, will prevent it going far, and there is no danger of extravasation of feces into the abdomen, as was stated by de la Faye and Dessault, and the ligature will only increase irritation. In this case there must be a discharge of feces from the wound; but they have been often known to recover their natural passage after some time by the aperture of the intestine becoming agglutinated or healed by granulation. The next case is when the whole cylinder is found gangrenous, when our treatment must be, the sitting up the diseased portion, to let out its contents, and give an exit for fecal matter from the rest of the intestine, to facilitate which the stricture should be divided. The gut should then be left to slough away, and if the patient does not sink under this injury, he recovers with that loathsome disease an artificial anus, which, however, does not prove fatal if the bowel have been part of the colon or even ilium; but, if it have been a portion situated high up in the alimentary canal, the patient dies of inaction, there not being sufficient length of intestine to absorb nutriment. But this complaint if not

fatal is productive of great misery from the continual discharge of feces, which, however, do not smell so offensive as when retained longer. It is best treated by causing the patient to wear a slightly elastic truss, with a pad, which must be taken away when the patient feels a desire to discharge his feces.

When the omentum is found adherent we may use more freedom in separating it, by tearing up the adhesions; and if any vessels bleed, securing them. If the quantity be large, or indurated, we may cut off a great portion of it and tie all the vessels, which do not stop on being lacerated with a pair of forceps, leaving the ligatures hanging out of the wound, and reduce the rest to the mouth of the sac. When the omentum is mortified we should pursue the same plan of excision, &c; we may know it by the blood in the veins coagulating. Its color, however, is not like that of intestine, black or green, but of a livid dull red; and when pressed by the fingers it gives a sensation of sickness.

Treatment after the operation.—After the operation for strangulated hernia, there are two things from which danger is to be apprehended; the first, that the intestines may not perform their office, and the feces not pass in their natural course; secondly, and principally, that peritoneal inflammation may come on, and produce the same effects as if gangrene were present. The object consequently should be, as soon as the hernia is returned, to close the wound as completely as possible, by means of sutures, and to employ gentle pressure. But, if the hernial sac remains open, the integuments should be brought together by means of sutures, slight pressure should be made by dossils of lint, and the parts should be supported in a suspensory bandage.

The horizontal posture must be strictly ordered; and, in five or six hours after the operation, give a little sulphate of magnesia or castor-oil; the more motions your patient has, the better. We must not be satisfied if the patient have three or four motions on the following day, but keep up a constant discharge from the bowels; on the next day the abdomen will become tense, with constipation and constant vomiting, in which case we must bleed or purge freely. If hiccup now supervene, it need not be a symptom of gangrene, but peritoneal or intestinal inflammation. When the inguinal hernia is very large we need not lay open the sac, nor endeavour to reduce it; for its adhesions will be too extensive, but must content ourselves with cutting down to and dividing the stricture, leaving the hernia incarcerated.

2. *Direct, or ventro inguinal hernia*, comes down inside the epigastric artery through the outer ring, but not the inner one. The difference in the operation is, that it has another covering, viz. a portion of the fascia transversalis; and the artery lies to the outside of its abdominal aperture.

3. *Congenital hernia.*—In this the testicle cannot be felt at the lower part, and there is no peritoneal sac, or rather the sac is formed by what is to be the tunica vaginalis, which remains yet enclosed. There is no difference in the operation.

4. *Femoral hernia* is seated deeper and more laterally than inguinal. The symptoms of strangulation are more urgent than those of the latter, on account of the smallness and inelasticity of the aperture.

In operating for femoral hernia, you make your first incision in the course of Poupart's ligament, along the tumor, extending from one side to the other; the second you may make at right angles to the first, towards the umbilicus, so that the two incisions resemble the letter **J** inverted. The angular flaps are to be next dissected off, and reflected, so as to allow of greater room. By this incision you expose the superficial fascia, which you next divide, and the hernial bag, called by some fascia propria, is brought into view. This is next cut through, and the hernial sac, or peritoneal covering, makes its appearance. The next point is to make an incision into the hernial sac with the greatest possible care, and then introduce a director to ascertain the seat of stricture. Having opened the hernial sac, and exposed the intestine, divide the stricture directly upwards and inwards, a little inclined to the umbilicus. The seat of stricture in femoral hernia is at the crural arch, just where the intestine leaves the abdomen; therefore, in dividing the stricture, after introducing the director, a bistoury, blunted at the point, is to be put on it, and placed against the stricture; in this way there is no danger of wounding the intestine. The bistoury is next to be gently raised, and with a slight touch of the instrument, the fibres will give way, and by a little pressure the parts are easily returned.

5. *Umbilical hernia* must be treated like the others. There is no difference in the operation. In dividing the stricture we should cut upwards, and afterwards endeavour to heal the wound as soon as possible to prevent the liability to peritoneal inflammation.

PART III.

ORDER.—VENENANTES.

CHAP. I.—OF SYPHILIS.

Is the consequence of a specific poison applied, and absorbed into the system, producing at first an ulcer, called a chancre, at the place where it was so applied, generally on the organs of generation; the matter of which, being absorbed, gets into the glands of the groin and produces a bubo, and, continuing onwards, is received into the circulating system; when it produces eruptions and ulcerations of various parts of the body, particularly affecting the throat, skin, periosteum, and bones.

SECT. I.—OF CHANCERE.

The average time for its appearance is from four to seven days after connexion; but there appears reason to believe that the poison may be dormant for a much longer time. It begins first as a red spot which ulcerates, or as a pimple with a white head that falls off, and then ulcerates, or it may appear only as a vesicle; these all, however, form ulcers, having hard and ragged surrounding edges with a yellow surface and inflamed margin, also a hardness to be felt by the

fingers underneath it. But its appearances are also various; for it may consist of a solid gristly substance with very small ulcers; sometimes a sore on the broad surface of the glands, burrowing deep, with no surrounding inflammation. Sometimes it spreads quickly by ulceration or sloughing, and often bleeds.

Chancre situated on the frænum, or external meatus, is very difficult to heal, on account of the constant dribbling of urine on it; when it is situated on the edge of the prepuce it will make the part swell and cause phymosis. When the matrix of a chancre becomes indurated, the patient is more liable to secondary symptoms. There are other sores appearing on the penis of suspicious appearance, but which are not chancres, and not followed by secondary symptoms. Such are little ulcers on the prepuce, reaching as far back as the verona glandis; deep, irritable, and painful, presenting a honeycombed appearance, often attended by discharge from a swelling of the prepuce. These generally get well by stimulating them and several others.

Treatment of chancre.—It has been proved that chancres may now be cured without mercury; but nevertheless this is not so safe, as the patient is more liable to secondary symptoms, so that we should put him on a mild mercurial course, giving five grains of blue pill, with a quarter of a grain of opium night and morning, and so keep up a gentle action on the mouth, and dress the chancre with mild applications, the black wash is one of the best. But, if it be very indolent, we may touch it with the caustic. If the chancre heal quickly, we should nevertheless still continue the mercury for three weeks at least. Sometimes during the treatment a chancre becomes very irritable and much inflamed all round it. This may often have been produced by the action of mercury: in any case we must suspend all mercurials, apply poultices and sedatives, give opium internally combined with salines; and, when the irritation has subsided we may return to our mercury, giving also the compound decoction of sarsaparilla. Sometimes a chancre may take on the sloughing action, so as if not stopped even to destroy the penis. This may proceed from the patient's intemperate habits, or from the bad use of mercury. In this case the mercury must be stopped, and a lotion applied of from thirty to fifty drops of nitric acid to a quart of water, or warm spirits of turpentine, or strong solutions of opium with poultices. The patient must be allowed a generous diet and stimulant medicines, of which one of the best is ammonia with musk, or what is still better opium in one grain doses three or four times a day.

Chancres in women are often worse than in men; they attack the labia and nympha, and are to be cured by the same means.

Phymosis is induced by a great swelling of the prepuce, which causes the orifice to contract, so that it cannot be drawn back over the penis, allowing a lodgment of secreted matters which are unable to escape. They cause great irritation; and, if let alone, the prepuce will slough, allowing the passage of the glands through the opening.

The *treatment* consists in mitigating the inflammation, and if mercury be the cause it must be suspended, otherwise we must apply cold lotions, inject black wash under the skin, purge the patient and give him opium. If all these fail, we must introduce a director under the prepuce as far as the corona glandis, and slit it up with a bistoury; then make the internal and external parts correspond, (otherwise the internal will not be so freely divided as the external), and put a stitch into each side, which hinders the inner and outer edges from being so much separated by the swelling which takes place; dress it lightly that the patient may be able to readjust it when he makes water. Sometimes when the prepuce is very long it is better to cut a circular piece off.

Paraphymosis is applied to the state when a patient has retracted his prepuce behind the glands, but that swells and he cannot get it back again, so that there is a tight ligature round the glands, which, if it continued, would effectually strangulate it.

Treatment.—We must endeavour to reduce the size of the glands by pressure, and after some time push it back with our thumbs, drawing forward the prepuce with our fingers. If after several trials this do not succeed, we must introduce a director or probe under the stricture, then passing a sharp pointed bistoury along it divide the stricture. After this apply poultices.

Warts, though formerly considered venereal, are now not treated as such; any mild stimulus will remove them if soft, such as the liq. plumb. subacet. dil. when they are hard they should be poulticed, and then touched with an ointment made of arsenic, $\mathfrak{z}\text{i}$, cerate, $\mathfrak{z}\text{i}$, and this will make them slough.

SECT. II.—OF BUBOE.

When syphilitic is commonly confined to one gland (on either or both sides) situated high in the groin, which distinguishes it from those caused by irritation alone, when a chain of them is affected. It produces the same symptoms as a common abscess, and must be treated as such, but at the same time we should give mercury; except when it assumes a chronic form, in which case we should act on the bowels, and try to diminish it by leeches, lotions, &c.

Sometimes a buboe takes on a sloughing action, in which case we must treat it as sloughing chancre, but there is great danger of its opening the femoral artery.

A buboe often leaves a sinus, which must be injected with a solution of oxymuriate of mercury; and, if that fail, laid open.

A chronic buboe often presents a diseased gland at its base, which must be destroyed with irritating troches or the potassa fusa.

A buboe sometimes becomes a phagedenia ulcer. It had then better be dressed with a solution of nitrate of silver. Give bark, ammonia, and opium internally.

Secondary symptoms, may appear in a fortnight after contamination; but it is generally six or eight weeks, or sometimes even months before their occurrence. They make their appearance either by a sore throat, when it appears as if a piece had been dug out of the tonsils, leaving a

foul ulcer, not very painful, or eruptions preceded or not by fever. These are of various characters; the most common is the venereal lipra, consisting of copper colored blotches, circular, and little elevated; or a crop of either pimples or pustules may come out; or there may be red and conical tubercles, or the elevated brown rupia, shaped like a limpet shell, which falls off, leaving a deep painful ulcer. When the throat is affected, the eustachian tube often becomes blocked up, causing permanent deafness, which is only to be remedied by puncturing the membrana tympani. But the bones and periosteum become shortly after affected, causing nodes and caries, particularly of the bones of the nose and palate, both of which may be perforated by it. Another part liable to be attacked is the eye, in which a violent iritis appears, and syphilitic pains may attack any other parts of the body.

Treatment.—Mercury may be considered as the great remedy, but it must be discontinued if it disagrees with the patient. If there be much fever we may bleed. When the pains are severe, use the warm bath, give Dovers' powder, guaiacum, or colchicum. For eruptions, the warm bath is the best remedy; when there is mild sore throat it should be gargled; but, when severe, we must bleed or leech and blister it. Foul ulcers in it may be touched with the linimentum eruginis. Indolent ones with solution of argenti nitratum. When iritis supervenes, we must throw in mercury as quickly as possible, cup in the back of the neck or temples, and blister, and apply extract of belladonna to prevent adhesions of the pupil. When the bones are affected give sarsaparilla, or mercury. If the nodes are very painful cut them through down to the bone.

It not unfrequently happens that an opening is made in the bony palate, causing a disagreeable snuffing when the patient speaks. This after healing the ulceration may be stopped up with lint or cork, or an instrument invented by Mr. Weis of the Strand.

It is often of importance to know how mercury may be made to affect the system soonest. This indication is answered by the hyd. oxymur. internally, and mercurial fumigations externally, which is effected by exposing the patient to the fumes of cinnabar, thrown on to a red hot iron. When complaints arise from the use of mercury, we should give sarsaparilla or nitric acid, which prove very efficacious in stopping them.

SECT. III.—OF GONORRHEA.

(From *γονη*, semen, and *ρεια*, to flow). The derivation would imply that this disease was a flow of semen, but it is a flux of purulent matter from the urethra, formerly supposed to come from ulceration, but Mr. Hunter proved that there is no breach of surface, but that it is a secretion from the vessels of the urethra.

The *symptoms* generally arise in three or four days after infection, very rarely exceeding seven days, but may arise earlier than three. The patient first experiences a sense of titillation in the urethra, as if a drop of urine were contained in

it. This directs his attention to the part, and he finds that the lips of the urethra are red, and that there is a slight mucous discharge. Afterwards the urethra begins to be affected with considerable heat, and pain is experienced in voiding the urine, which state is called *ardor urinæ*. The pain increases till it becomes, in many cases, excessively severe; there is an appearance of threads mixed with the urine, which arises from the adhesive inflammation in the lacuna of the urethra. The next effect is a considerable diminution in the stream of urine, the swollen state of the urethra contracting the size of the canal. The urine is often discharged in two, three, or more streams, in consequence of the contracted and irregular state of the urethra. At first the discharge from the urethra is mucous, but after a little time it assumes a purulent appearance. The matter becomes yellow, and, if the inflammation is very considerable, green; and it is often intermixed with blood, so as to give it a sanious appearance. The glands of the groin are generally sympathetically affected, and, in a first gonorrhœa, seldom fail to become enlarged and painful. They very rarely go on to the formation of matter, if proper attention is paid on the part of the surgeon.

Chordee is a not unfrequent accompaniment to gonorrhœa. It is a painful erection of the penis, which feels bound down and is either curved or bent considerably to one side, being caused by inflammation and effusion of lymph into the *corpus spongiosum*. There is often a great irritation of the muscles of the perineum, producing violent spasmodic contractions. If any constitutional disease, as a fever, occurs during a gonorrhœa, the discharge will be suspended till the constitutional symptoms abate, and will then re-appear.

Treatment.—If it be a first attack there is always more irritation, so that it will be advisable to begin with saline purgatives, and afterwards to use *colocynth* and *calomel* as mere aperients. The patient should at the same time use diluent drinks, such as nitre, subcarbonate of potassa, or soda dissolved in mucilage. When any of these increase the irritability of the bladder they are to be discontinued. If the penis be much inflamed with chordee we may apply leeches; and, if the constitution sympathises, a general bleeding will be very useful. Hanging the penis in warm water mitigates the difficulty of micturation, and when the *ardor urinæ* and pain from chordee are very great, we may give twenty drops of the *liq. potassæ*, with from three to five grains of *conium*. After the first week we may apply cold saturnine lotion to the penis; and, when the inflammatory symptoms have abated, give the balsam of *copaiba* in doses from twenty to thirty drops, morning and evening, and when this has made an impression on the discharge we may begin injections, of which one of the best is the *liq. plumb. subacet. dil.*, afterwards made stronger by the addition of *sulph. zinci*.

In subsequent attacks we need not be so cautious, but begin at once, if there is not too great an irritation, with doses of *copaiba* and *cubibs*, and shortly after to commence with the

same or various other injections, such as half a grain of the sulphate of copper in an ounce of rose water, or one grain of *oxymur. hydr.* in twelve ounces of water: these two are very powerful, but the strength of injections must depend on their effect. If there remains much gleet we should introduce bougies, which will stop it. The treatment of women does not differ from that of men, except that we need use less caution. During the latter stage of gonorrhœa it often happens that the bladder becomes very irritable, so as to cause desire to make water every quarter of an hour, which when voided is often mixed with blood.

Treatment.—Opium should be given in doses of from one to two grains, with a view of allaying the pain and irritation; and, with the same object, five or six grains should be introduced into the rectum in the form of suppositories. The *liquor potassæ* with opium or some bitter tincture is also recommended; castor oil as a purgative; and, after shaving off the hair, a blister should be applied over the region of the pubes: the counter irritation thus produced will prove of infinite service.

Swelled testicle, or *hernia humoralis*, is a frequent result of the use of the bougie, or shows itself in from ten to fourteen days after the discharge. When confined to the *epilydymis* there is little pain; but, when it extends to the body itself, the unyielding nature of the *tunica albuginea* causes much pain. We may first foment them, and purge the patient; and, if this does not succeed, apply leeches, cold lotions, &c.; and it is sometimes necessary to give anodynes at night.

Bubo may arise from gonorrhœa, but rarely suppurates. It must be treated as other buboes.

Gleet may be only a symptom of stricture; but if it be the sequel of gonorrhœa it is often difficult to cure, and, to accomplish it, we must use both constitutional and local remedies. Balsams, turpentine, and cantharides, are useful, but generally produce their effect in five or six days, so that space of time may be considered as a fair trial. When the whole system is weak we may prescribe cold baths, bark and steel. The local applications may be either injections or passing bougies. Gleets have also been cured by counter irritants, as a blister under the urethra, &c.

CHAP. II.—OF HYDROPHOBIA.

From *ὕδωρ*, water, and *φοβος*, fear. This most melancholy and dangerous disease is the consequence of bites by rabid animals, particularly dogs, cats, and wolves. The poison resides in the saliva of the mad animal, and so is introduced into a wound by the teeth. This disease is generally some time in showing itself after infection, hardly ever earlier than a fortnight or three weeks, and in some instances as late as several months.

Symptoms.—At some indefinite period, and occasionally long after the bitten part seems quite well, a slight pain begins to be felt in it, now and then attended with itching, but generally resembling a rheumatic pain. It soon extends from the wound up to the arm, and affects the situation of the *trapezius muscle*, and the neck.

on the same side as the bite. The cicatrix, in the mean while, begins to swell, inflames, and at length discharges an ichorous matter. There are often pains of a more flying, convulsive kind, felt in various parts of the body. As the disease advances the patient complains of the pain shooting from the situation of the bite towards the region of the heart. Lassitude, a dull pain in the head, and a vertigo, soon come on: the patient is commonly melancholy, though not always, mutters, is forgetful, and drowsy; his mind seems disordered; his temper irritable and irregular; his slumbers disturbed, and convulsive agitations immediately follow his waking; a deafness is sometimes complained of; the eyes are watery; the aspect sorrowful; the face pale and contracted; sweat breaks out upon the temples; and an unusual discharge of saliva is made from the mouth. From the beginning a peculiar stricture and heaviness on the breast, occasional involuntary sighing, and nausea take place. There is often a bilious vomiting. The idea of drinking any kind of fluids creates considerable alarm and agitation, and the attempt to do so generally brings on most afflicting pains and convulsions, attended with a dreadful sense of suffocation and choking. These soon come on without any attempt to swallow; the patient becomes delirious, and dies, exhausted by continual and furious ravings. The time in which the attack proves fatal varies from thirty-six hours to three or four days.

Treatment.—There has yet been nothing discovered that can contribute to the relief of this formidable malady. It has lately been proposed to inject warm water into the veins, and at the same time abstract blood: its success is as yet doubtful. There is, however, one thing that lies in the surgeon's power. It is to excise or destroy the bitten part as soon as possible after the accident, not allowing the smallest portion to remain which will ensure the patient's safety. But all people who are bitten are not affected by the complaint, especially if the bite has taken place through much clothing, so that the saliva of the animal may have been wiped off from the teeth. When, however, symptoms do come on, they are next to certainty fatal.

CHAP. III.—OF DISSECTING WOUNDS.

These have lately attracted the serious attention of surgeons especially, from the number of fatal events caused by them within these last few years. The violence of their symptoms seems to depend on the particularly noxious qualities of putrid, applied to live animal substance. These, however, differ from the last mentioned disease by affecting persons with every degree of violence, sometimes very lightly, at others fatally; they, however, resemble the last in not contaminating alike all persons, seeming to attack most vigorously those who have been previously debilitated. When a person inoculates himself with dead animal matter it produces these symptoms: the wound becomes painful and inflamed; the inflammation spreads up the arm, affecting especially the absorbents, which is demonstrated by indurated red lines over their course; the glands of the axilla become affected; a symptomatic typhus

seizes the patient; the arm swells, or becomes erysipelatous; matter forms under the fascia, or in the glands of the axilla; and the patient often sinks under symptoms of the most malignant putridity. But, when the disease attacks a person of more robust constitution, it puts on quite another appearance, being then a mere inflammation of the absorbents, which may stop at any period of its course. Its treatment must depend then on the form it assumes. When it is inflammatory it is to be treated like other inflammations; but, when it puts on the putrid form, it is better to take a small quantity of blood from the system first; then apply warm and soothing applications to the wound and arm; give the patient cordials with doses of opium; and, if matter forms, give it a ready exit.

There is a form in which this disease appears in persons who are much in the habit of handling offals. This consists of an erysipelatous blush over the hand, with considerable swelling and running from one finger to another, remaining a long while. This may be cured by mercurials, particularly the oxymuriate in small doses.

CHAP. IV.—OF LETHALES, from application of substances tending to direct destruction of vitality.

SECT. I.—OF BURNS AND SCALDS.

These may affect persons in very different degrees, which are visible directly after the accident, as they produce three distinct effects. These are, 1. Mere vesication. 2. Desquamation. 3. Mortification of the skin.

1. *Vesication.*—This form is not dangerous, although it be of considerable extent; it is usually produced by scalding water. We should not open them in the first instance, but allow the inflammation to subside first, and then they may be opened with advantage. The best applications are cooling and sedative ones first, but when we open them, they heal best by being sprinkled with a little very finely levigated chalk, or calamine.

2. *Desquamation.*—In this the cuticle separates at once, leaving the cutes exposed and inflamed, and ready to slough. This is the most painful variety of burn, and dangerous in proportion to its extent. Patients who die of large burns are found to have sometimes inflammation of the lungs, at others ulceration of the intestines: various remedies have been proposed for this form of burn. But the best seem the following:—When the patient is chilly or much exhausted by its violence, give stimuli internally, as opium and wine, &c. But as soon as reaction takes place, we must take care it be not too violent, to mitigate which we must employ our means for inflammation, and even bleed if necessary. Our local treatment must be to prevent the tendency to sloughing, for which purpose we must keep up an irritation by means of lime-water and oil, or milk spread over the part, or, what is still better, spirits of turpentine; but, if this last gives too much pain, we may dilute it with oil, &c. This must be continued till re-action takes place, when we apply milder dressings. When contiguous parts are burnt, we must interpose dressings to prevent adhesions.

3. *Mortification*.—When this is produced at once, the patient feels no pain; but it is the most dangerous, either killing the individual by the sudden, severe, shock to the nervous system, or else on the separation of the sloughs causing such violence of re-action that it proves fatal. The treatment is the same as for common gangrene. Poulices, in the first instance, are sanctioned by the highest authorities, as no stimuli can act on the dead matter. We must give wine, opium, and ammonia to support the constitution. When burns heal they leave large cicatrices which keep gradually contracting. It has been proposed to divide them longitudinally, and let them heal so, or to cut out the whole cicatrix and bring the sides together; this last, however, can seldom be necessary, as it is always in the surgeon's power to heal them at first in this manner.

SECT. II.—OF FROSTBITES.

Frostbites affecting particular parts have been already noticed under the head gangrene. It remains now, to treat on that state in which the whole body has been affected with cold. In this case the patient experiences a drowsiness steal over him, followed by an irresistible desire to sleep; which, when he gratifies by lying down, proves fatal; for, so long as he continues any exercise, heat enough is generated to preserve life, but as soon as he ceases his exertions, there is no longer a sufficient supply for the rapid abstraction, his senses desert him, the brain can no longer furnish the body with sufficient vital energy, and he dies quietly and insensibly. When, however, a person is discovered before the fatal termination, we must use every exertion to re-animate him, by restoring warmth in the most gradual manner; and for this the best plan is to rub the body, or envelope it in snow or ice water, which will gradually thaw it. Sternutories are to be applied to the nostrils, and cordials introduced to the stomach. But, above all, artificial respiration is to be carried on, either naturally or by opening the trachea. The body is now to be laid between two blankets and rubbed constantly, augmenting the temperature as gradually as circumstances will permit, and this treatment will often succeed in restoring persons apparently lost. If the frozen parts are incautiously heated they will mortify.

SECT. III.—OF CHILBLAINS.

Chilblains are a less violent effect of cold, consisting of an inflammation with diminished vitality, and thus liable to slough when severe. The symptoms when mild are, swelling, with heat and itching, after a time spontaneously disappearing. In a more severe form, the tumor is larger and redder, sometimes of a dark blue color. The heat, itching, and pain so vehement that the patient cannot use the part. In a third form small vesicles arise, which burst, leaving ulcers which penetrate deeply, and secrete a thin matter; they are very slow in healing. In the worst cases, the inflammation ends in mortification.

Treatment.—One of the best applications to chilblains of the first and second sort is ice-cold water. The part affected is to be immersed in

it a few minutes, two or three times a day, until the complaint quite disappears. This event usually happens in less than four days. After every application the part is to be well dried, and covered with leather socks.

In some cases tonics and astringents have had the best effect. Such are diluted muriatic acid; the saturnine lotion; spir. vini. camph.; tinct. myrrh; the alum lotion, vinegar, &c. In other instances, oleum terebinthinæ mixed with the balsam copaivæ; and a mixture of two parts of spir. vini camph. and one part of aq. litharg. acet. have proved the best applications. Suppurated chilblains require topical stimulants, such as warm vinegar; a mixture of aq. litharg. acet. and aq. calcis; or a salve containing the hydrarg. nitrat. rub. It is frequently necessary to touch the ulcers with the argentum nitratum. Gangrenous chilblains must be treated according to the rules explained in the chapter on mortification.

CHAP. V.—OCCULTI, cause not apparent.

SECT. I.—DIFFUSI, affecting the system at large.

1. *Scrofula*, scrofa, a sow, because supposed to affect swine. This disease shows itself more particularly in young people or children than in adults, and has been noticed to exist in those, especially females, of florid complexion, light hair and eyes, long eyelashes, and dilated pupils, with a thick upper lip, and adune nails, generally of precocious intellect and lively dispositions. The forms in which it manifests itself are various, but attacks chiefly the absorbent glands and joints. When a part suppurates it does not contain pure pus; but this last is mixed up with flakes of unorganized lymph looking like curd, or sometimes thick like cheese. The ulcers which it produces are always very indolent with livid purple margins. This disease seems to be hereditary, and more common in cold climates.

Treatment.—There is no one medicine that has specific influence over this disease; but our object must be to strengthen the patient, and give a firmer tone to the body. If it be a child the diet should be nutritious, but not stimulating; and meat plainly cooked should not be allowed more than once a day, the rest should be farinaceous. There are indeed exceptions to this; for when a child is very much emaciated, or does not improve upon the light diet, we must then allow it animal food often, and but a little at a time, in preference to vegetables, and also a slight stimulant, as good beer or wine, if it does not prove too irritating. The patient should not be exposed to change of weather, and his clothing should be attended to. But air and exercise will prove of the greatest utility, particularly sea air and bathing, which, however, should not be continued for more than six months at a time and then varied. The bowels should be kept open, giving occasionally a purgative of calomel and rhubarb; and courses of bark. Steel, sarsaparilla, or liq. potassæ may be given, varying them also, and persisting for several months.

2. *Hysteria, vorepa*, the womb, because this is thought to be the cause of it, is a diseased state of the nerves to which women are subject, though many surgeons have seen positive cases of it in men who lead sedentary lives. It does not show itself till puberty, and therefore there is reason to suppose it connected with the genital organs. It appears especially in young and unmarried females who do not take sufficient exercise, and consequently are often stout; but it is not confined exclusively to either of these states. The symptoms it produces are, fits of convulsions, with laughing and crying, &c.; but these are generally treated by the physician, and it is only the anomalous symptoms that fall under the province of the surgeon. These are very various, but it is of consequence that they should not be confounded with real diseases.

Thus we find difficulty of swallowing, loss of voice, retention of urine, pains in various parts, as the breast, knee, spine or sides, particularly the left. These pains come on gradually, and after some time occasion a little puffy swelling, which is marked by being as tender when touched very lightly as if pressed heavily; these are sometimes very severe, and last for months or years; but still they do not impair the patient's health or disturb her rest. They are very common in the joints, as was noticed by Mr. Brodie; they sometimes leave one part and attack another.

Treatment.—If originating from want of exercise or other constitutional causes, such as an impaired menstruation, the remedies will be obvious; but these are often not to be detected, in which case, when the pain is severe, we must apply a lotion of sp. rosmar. ζij . mixt. camph. ζvi ., or a belladonna plaster. The best constitutional remedies are valerian and ammonia.

3. *Cancer.*—Cancer, Latin, a crab; because the tumor with the surrounding enlarged veins has a distant resemblance to a malignant disease which attacks indiscriminately all the structures of the body, particularly glandular, beginning by a hardening, and ending in ulceration and sloughing. There are two varieties: 1. The common hard cancer: 2. The soft cancer, or fungus hæmmatodes.

1. *Common cancer* is known in two distinct states. 1st, before it has ulcerated, when the name schirrus has been applied to it, from $\Sigma\chi\text{ρ}\rho\omega\omega$, to harden. 2dly, After ulceration, then called open cancer; but these are but stages of the same disease.

Symptoms.—In incipient schirrus there is nothing more apparent than an indurated cartilaginous tubercle, affected by acute lancinating pains, though these do not come on sometimes till later in the disease. Ligamentous bands may often be felt intersecting each other, leaving spaces mostly filled with fluid; the skin becomes puckered over it; discolored; and, by and by, ulcerates; the ulcer having thick wetted edges, discharging a thin ichor, not pus, extremely fetid; the progress of it is generally slow, but it sometimes spreads quickly, sloughing at times and causing profuse hæmorrhages; fungous growths often sprout up; it contaminates every part near it, and so increases in

size. This indeed happens some time before the morbid growth shows itself. Then it affects the neighbouring chain of absorbent glands, which are also converted into cancerous structure; and, at last, the patient dies emaciated and exhausted. Fungus hæmmatodes is a white, soft, medullary substance, having sometimes ligamentous bands, and a feeling as if there were water in it. It is generally contained in a cyst; there is no structure or age exempt from it, whereas cancer is a disease of advanced life. It does not contaminate the absorbent glands, and is not so painful as cancer, but it spreads by contaminating the parts around.

Treatment.—No medicines of any sort have the least power of cure over these formidable diseases, but they may be removed by an operation; though even this is not always successful, as the disease often exists in the constitution; but by it the patient is saved for a time, and enjoys a few years more of valuable life; or he may in the mean time die of some other, and not so terrible a disease. If the operation be not successful, in removing every portion of disease, it will aggravate it, and the symptoms will re-appear with increased violence, so that we should in some cases hesitate to operate; for instance, where the disease exists in two places at once, or in very old people, or where it is indolent and may last for years, or when the skin is contaminated and much ulcerated; for in this case the malady will mostly re-appear either on the matrix or some other part. In cases where the operation cannot be done, keep the patient quiet; apply cold lotions, low diet, and occasional purgatives. If there be ulceration, a carrot or hemlock poultice, or black wash, or oxyd of bismuth ointment.

CHAP. VI.—LOCALS.

SECT. I.—DISEASES OF BONES.

Inflammation may exist in either an acute or chronic form, but generally the latter, producing an enormous swelling of the limb, with pain and more or less fever. This may produce two effects, 1. Suppuration; 2. Necrosis.

1. *Suppuration* in bones has received the odd name of spina ventosa. If it be acute the pain is excessive, on account of its unyielding structure; but it gradually swells and bursts, generally forming several sinuses in the skin and soft parts, which require a long time for healing, as the bone mostly exfoliates. This inflammation is to be treated as any other in the first instance, and, as soon as matter is suspected in the bone, an opening should be made with a trephine. If it is long in healing, the patient's strength must be supported by tonics and generous diet.

2. *Necrosis, νεκρος*, dead.—By this is implied the death of bone that takes place, either in consequence of inflammation or from separation of the periosteum. It has been used improperly by many writers as synonymous with caries, but the latter is analogous to ulceration, the former mortification of soft parts. Necrosis attacks dense bones most frequently, as they have least power to resist injury, and so die; when this takes place in long bones, or where the periosteum

teum is not destroyed, the latter forms a bony case round the dead portion, which is now called a sequestrum. This generally separates into several portions, each of which may have an external opening by means of a fistulous sinus, from the mouth of which there mostly arises a fungous granulation, and, if left alone, each portion of separated dead bone is brought by the action of the live parts to present itself at the external opening; but this is a very tedious process, and wastes the patient's health and strength by the constant discharge, with occasional febrile attacks.

Treatment consists in supporting the patient's strength, and leaving the rest to nature in most cases; taking care to prevent the lodgment of matter, giving free opening to the discharge, and dressing the sores lightly; and, when a piece of bone is to be felt, separated, we must take it away by enlarging the wound; but, if the case does not go on favorably, and there seems no separation of the dead parts, then the surgeon should cut down upon the new shell, and remove a portion by a trephine or inllet and gouge, and draw out the dead pieces from the opening. But there are also cases in which the patient's health is rapidly sinking, and then we must amputate the limb to save his life.

3. *Caries*, from κείρω, to abrade. An ulceration in bones, similar to that in soft parts, is often caused by matter locked up in bones, as between the tables of the skull, but is often caused by other diseases, as syphilis, scrofula, &c.; in which cases it attacks the soft or spongy bones, some of which have been mentioned, and others will be hereafter. When a caries is accessible, Boyer recommends touching it with the actual cautery, which changes it to a necrosis, and stimulates the parts underneath to throw it off. If a carious portion is contained in the canulli of long bones, we should trephine them.

4. *Exostosis*, from ἐξ, out, and ὀστών, a bone, is a morbid growth of matter from a bone, generally not painful in itself, but occasionally by its size pressing on the neighbouring nerves, and thus giving a great deal of pain. There are two sorts, one hard and bony, generally arising from the periosteum, into which spicula of bone shoot; the other a fungous growth from the canulli, surrounded by a shell of bone. The first sort often becomes inconvenient from its size and pain by pressure on nerves; and, when it is situated in accessible parts, it may be removed by a saw, or gouge and mallet; but otherwise the limb must be amputated: the latter affection cannot be removed by an operation, on account of its malignant tendency; so that amputation is here our only resource: and it should be noticed that, if the disease exists at any part of a limb, we cannot ensure the rest of the bone being healthy; so that it is advisable to remove the whole limb if possible.

5. *Rachitis*, from ραχίς, the spine of the back. Weak, and particularly scrofulous children, are subject to this disorder, in which the bones, in consequence of a deficiency of lime in their structure, cannot bear the weight of the body, and become distorted. In infants, who are too young to walk, the action of the muscles is suf-

ficient to make the bones, particularly those of the lower extremity, deviate from their natural figure. There are various mechanical contrivances sold in London for supporting rickety bones, and gradually restoring them to a straight figure. It is not necessary to offer here a description of any apparatus for the purpose. Bark, tonic medicines in general, and cold sea-bathing, improve rickety children by strengthening the system; for, in proportion as this happens, the phosphate of lime becomes secreted in a more regular manner, and, with the aid of mechanical contrivances, very great deformities are gradually removed.

6. *Mollities ossium*.—The bones sometimes in adults become remarkably soft and flexible from a deficiency of phosphate of lime, and so are bent by the action of the muscles. No means of cure or prevention are yet known.

Distortion of the spine may exist in two ways, 1st, there may be a single or double lateral curvature without caries of the bones; 2dly, a projection of the spinous processes caused by caries: the lateral curvature is caused by the weakness of the muscles supporting the spine being overcome by the weight of the head and shoulders, forming a bend to one side, generally near the loins, in which case the patient is obliged to make another bend near the shoulders to allow the head to rest perpendicularly on the pelvis; and there is generally a prominence of the hip, usually the left. It may be produced, however, by other causes besides mere weakness, as a constant unvaried position; for, in this complaint (which mostly occurs in young females), not only are the muscles weak, but also the ligaments allowing of considerable elongation.

Treatment.—Strengthen the system generally by tonics, air, and exercise, particularly on horse-back; change the position often; attend to the function of menstruation that it is performed rightly, and exercise gradually the muscles of the spine, allowing the patient to rest in the horizontal posture after such exercise. But sometimes this disease is combined with rickets in which case the patient must wear some instrument when she is not being exercised, to take off the weight of the head, and give a moderate support to the spine; such a one has been made by a Mr. Laurie of Bartholomew's Close Smithfield.

Caries of the spine, causing absorption of the bodies of the vertebræ, and projection of the spine, with pressure on the spinal marrow, generally exists as a symptom of scrofula, and may attack either the bones or cartilages, producing, when it shows itself, paralysis, total or partial, of all the parts below the disease: its symptoms vary a little, according to the part attacked; thus, in the loins, the patient first begins to feel a loss of motion in his legs and thighs, causing him to trip, succeeded by a numbness or pain; there is also pain in the lumbar vertebræ, quick pulse, shiverings, and an abscess takes place in the psoas muscle, presenting itself under Poupert's ligament, or in the loins: the surgeon, upon examination, also finds a projection of the spinous processes, which are tender when struck or pressed.

Treatment.—We must, in the early stage, endeavour to prevent suppuration, by keeping the patient in bed, cupping on the loins, and the application and continuation of caustic issues near the affected part. If, however, abscess does present itself, we should open it, and let it heal up again, taking care not to use violence to it, or we shall bring on inflammation of the cyst, which produces symptoms of the worst typhus, from the matter in it becoming putrid. In this case we must open the abscess, and give wine, ammonia, and bark, and the inflammation may subside in a few days. When a psoas abscess has continued open, the patient becomes hectic, and seldom recovers.

Caries of the back.—In this, as in the other, there is difficult motion below, with pain on pressure; and the patient soon becomes unable to walk at all, not from complete paralysis but from violent spasms of the muscles. There is not much tendency in this case to form abscess.

Neck.—When this is diseased, the upper extremities are paralysed as well as the lower ones; there is also difficulty in breathing, and the bladder is often paralysed.

Treatment.—If ever this disease is cured, it is by ankylosis of the bones taking place, and in children this is not uncommon, but adults have not so good a chance of escape, as it then mostly proves fatal. This may be assisted by perfect rest and abating the internal inflammation by counter irritants, as caustic issues.

8. *Diseases of joints.*—Inflamed synovial membrane, as described by Mr. Brodie, is either a constitutional or local disease, and acute or chronic. When local it produces pain in the joint, exasperated by motion, soon followed by swelling of the joint spreading into the extensor muscles and on each side; and fluid may be felt to fluctuate, which is effused synovia. If acute, there is a symptomatic inflammatory fever. In treating this form we must bleed both generally and locally; and if the pain be violent we may apply warm fomentations and poultices; if not, cold lotion will be more serviceable. When the acute stage has subsided it leaves a swelling of the joint from, 1st, thickened capsule; 2dly, effusion of lymph into the surrounding skin; 3dly, effused synovia in the joint. And now we are to apply either one blister, keeping it open, for some time, or a succession of blisters; and then, if there remains any swelling or stiffness, we must use stimulating liniments. When it proceeds from gout or other causes, give colchicum; if rheumatic calomel and opium, or Dover's powder. When we have subdued the disease, Mr. Brodie strongly recommends the use of plasters and bandages to support the joint. Sometimes the disease assumes a chronic form; and, if neglected, the synovial membrane becomes altered in structure, appearing like a medullary sarcoma, which suppurates and ulcerates, extending first to the cartilages, then to the bones themselves; abscess forms in the joint, bursts, and the patient dies of hectic fever if the limb be not amputated. This then should be attacked vigorously in the early stage by rest, leeches, blisters, and cold lotions, and a milder climate may be tried if other remedies do not succeed.

9. *Ulceration of the cartilages* may be brought on by other diseases, but when it exists as an idiopathic disease, unconnected with scrofula, it produces these symptoms:—1st, When it attacks the hip joint there is at first pain referred to the knee, which gradually increases, when it may still be referred to the knee or sole of the foot, and is more severe during the night. It is aggravated by moving the limb, particularly pressing the head of the femur into the acetabulum. The nates become flattened and appear wider; the limb wastes, and in the early stage appears longer but in an advanced period shorter, and the toes are turned in; but, as yet, there is no real difference, the appearances being caused by the twisting of the pelvis. But at last the bone becomes dislocated by the absorption of the acetabulum and its own head, so that the muscles pull it into the dorsum of the ilium, but the capsule remains entire. Abscess now forms in the joint, marked by rigors, which shows itself externally, often at some distance, and is followed, when it bursts, by hectic fever.

When this disease exists in the knee joint there is pain in the knee which keeps increasing; it becomes a little swollen from effusion of lymph outside the joint, and the muscles, both above and below, waste away; matter soon forms in the joint, bursting at the inner or outer side of the knee, which may also be dislocated into the ham.

Treatment.—A most essential remedy for this disease is perfect rest. If there be much inflammation and fever we may bleed, cup, or leech. Issues should then be made near the joint with potassa fusa. When there is an abscess presenting we should puncture it, and allow the matter to escape, and the abscess to take its chance of either healing or remaining open; and give the patient tonics, and place the limb in the most favorable position for ankylosis, if this favorable event should take place; but in older persons this is rare, and they will die of the complaint unless the limb can be amputated.

10. *Scrofulous joints.*—This differs from the last in this respect, that whereas in the former the disease commenced in the cartilage extending to the bone, in the scrofulous disease, it commences in the cancellous structure of the bone, which (says Mr. Brodie) first becomes very vascular, then the earthy matter is absorbed, causing the bone to become soft, then a yellow cheesy substance is deposited in the cancelli; the morbid affection now spreads to the cartilages, causing them to ulcerate, and an abscess is formed, making its way outside the joint amongst the muscles, and sometimes a small portion of bone exfoliates into the articular cavity. This is a disease of early life, and sometimes exists in more joints than one in the same individual.

The *symptoms* which this disease produces do not differ in the later periods from those of the last affection; but in the first instance there is swelling of the joints of some duration, with little or no pain; this, with the aspect of the patient, enables the surgeon at once to decide upon the case.

Treatment consists in applying antiphlogistic remedies when there is pain, and putting the

joint into splints to keep it perfectly quiet. We must be cautious how we use counter irritants, as they frequently aggravate the disease; they, however, are admissible when the pain is severe. We should trust, however, chiefly to rest and the constitutional treatment recommended for scrofula.

Loose cartilages are generally found in the knee joint, and often exist without any traceable cause. They are at first connected with the synovial membrane, but soon become detached. Their size varies considerably.

Symptoms.—They sometimes give no pain, but this is rare; for in general they slip down into the articulation, giving a sudden and severe pain, causing the person to fall down; followed by inflammation and swelling of the joint, which lasts for some days and even weeks. Sometimes they become fixed in the joints, hindering all motion for some time.

Treatment.—We should endeavour to secure it in any part of the joint by pressure, which may cause it to adhere to that part, and so remove the inconvenience; but if this fails, which it generally does, we may remove it by an operation, if the joint be not otherwise diseased, which is not however unattended with considerable risk, from making a wound into a joint, so that it is only to be done in urgent cases.

When we set about removing it we must previously fix it by the fingers, if possible, at the inside of the joint, for there the parts are thinnest; and, drawing aside the skin, cut at once upon the body and seize it with a tenaculum. By this retraction of the skin the external wound is made valvular into the joint, which, by excluding the ingress of air, materially diminishes the risk of inflammation. It is almost needless to add that the patient must be kept in bed, and very quiet, till the wound has quite healed.

SECT. II.—DISEASES OF ARTERIES.

1. *Ossification* frequently takes place in persons of advanced age, but does not generally produce many symptoms of itself, though it lays the foundation of other diseases, as ossified arteries are liable to rupture. In this way are produced apoplexy or hæmatocele; but they act in another manner, by not allowing themselves to be filled with blood, or by a diminution of calibre, depriving the parts which they ought to supply of their proper nourishment, as is manifested in the gangrene of the toes in old people, and angina pectoris, caused by ossification of the coronary arteries of the heart. These, however, are diseases that cannot be remedied by art.

Aneurism (*ανεύρισμα*, to dilate) may be defined to be a pulsating tumor, containing blood and coagulum, communicating with the inner coat of an artery, which, if left to itself, gradually becomes thinner, till at last it bursts and proves fatal by the profuse hæmorrhage. Aneurisms are met with chiefly on the larger arteries, and may be produced by various causes; but the most frequent is a diseased state of the inner coat causing it to ulcerate, or burst suddenly, on an extraordinary exertion being made. They may also be caused by wounds of arteries. Aneurisms used formerly to be divided into true and

false; the true one being considered a dilatation of the coats, the false one a wound in the artery which caused a condensation of the surrounding parts to form a sac. But professor Scarpa has denied that aneurism ever can take place without rupture of at least the inner coat of the artery; and to which assertion, when a little modified, few modern surgeons have dissented. The formation of an aneurism is as follows:—The inner coat of an artery being diseased, either ulcerates or bursts from sudden violence, and the muscular coat, being unable to bear the impetus of the blood, gives way also. Thus all its force is borne by the cellular coat, which, being distensible, causes a tumor which resists for some time, but at length yields also, and the blood is received into the cellular membrane, condensed by the previous pressure of the tumor. And now the blood becomes coagulated, and forms successive layers of febrine, inside the sac, which still increases in size by the force of the pulsation of the contained blood. But this increase in size is attended with a diminution of thickness of the layers of lymph, which at last give way at one point; the sac bursts also, and the patient dies of internal or external hæmorrhage.

Symptoms.—These differ as the disease is situated in internal or external parts. When externally there is a small tumor pulsating strongly which may be reduced in size by pressure, on ceasing which it again returns, producing a numbness and spasms in the limb. It increases in size and becomes of a dark color. A small slough of the skin is produced, which bleeds alarmingly on separation, and may either kill the patient at once or by repeated bleedings. Internal aneurisms cannot be known at first; they produce disordered function in any part to which they are near, and absorption of all bony and hard structures that they touch. Tumors sometimes are situated over arteries; in which case you may feel them pulsate; but they may be known by not pulsating in every part as an aneurism does, but only directly over the artery which vibrates through them. They may also be sometimes moved from the artery, in which case there is no pulsation in them. In some very thin persons the abdominal aorta may be felt to pulsate through the integuments, and this may be mistaken for aneurism.

Aneurism, however, may be produced by other methods; there may be a dilatation first of the whole calibre of an artery, as described by Mr. Hodgson, which in time bursts, and so forms an aneurism.

Aneurism is also caused by wounds of arteries, when it may either condense the cellular structure round it and form a common aneurism, or extravasation may take place into the whole limb, which, being constantly augmented, may press on every part so severely as to cause gangrene; in which case the limb must be amputated.

Treatment.—Aneurisms, in about one case out of twenty or thirty, undergo a spontaneous cure by pressing on the artery above till it becomes obliterated, so no more blood passes into the sac and it is absorbed. But as this is so rare it is never relied on; and it is the duty of the sur-

geon to cure the disease by an operation. This was formerly practised by cutting into the tumor, turning out the coagululum, and tying the artery at both ends; but this was a severe and bloody operation, and often failed, because the artery was diseased where the ligature enclosed it, so that secondary hæmorrhage came on. This attracted the notice of Mr. J. Hunter, who, seeing the process that nature established for a cure, proposed imitating it by tying the artery before it came to the sac and at some distance from it, to have a healthy artery to operate upon. This was accordingly done in popliteal aneurism, by taking up the artery in the thigh where it passes under the edge of the sartorius muscle; and it succeeded and is the operation now practised, that is to say, the surgeon must tie an artery, for aneurism, as far from the tumor as he well can, taking care that he does not separate the artery more than he need from its connexions; and that no large branches are given off immediately before the ligature, as in this case there will be no room for the formation of a coagululum, and there will be hæmorrhage when the ligature comes away, and he should on no account use a broad ligature. After the operation the wound is to be brought together by adhesive plaster, leaving one end of the ligature hanging out, the other being previously cut off, leaving also between the strips of plaster small spaces for the escape of matter. Care must be taken in cold weather to preserve the warmth of the limb, which if it were suffered to lose too much heat would mortify. The ligature generally comes away in from twelve to fourteen days.

There are, however, many cases in which the surgeon must operate close to the tumor, as subclavian, carotid, inguinal, or hiar aneurisms, all which arteries have been tied successfully. Also in cases where there is a recent wound of an artery, with extravasation, the surgeon had better cut down upon the wound through the coagululum and tie the vessel above and below. In aneurisms on the scalp, from a blow, the surgeon had better cut it quite through and then apply firm pressure.

Varicose aneurism occurs from a puncture of an artery through a vein, which openings become permanent whilst the external ones heal. This causes an enormous dilatation of the vein over the artery, by the rushing of the blood from the artery into the vein, which also renders the color of the vein more arterial; and there is not a distinct pulsation but a feeling of whizzing. This, if the artery and vein are in contact by the formation of adhesions between the two wounds, becomes stationary after a time, and does not require any interference; but it more commonly happens that an intermediate sac forms between the artery and vein, which may increase so as to render an operation necessary.

Aneurism by anastomosis.—This is the term which Mr. John Bell, of Edinburgh, has given to a species of aneurism which resembles such bloody tumors (*nœvi materni*) as appear in newborn children, grow to a large size, and, ultimately bursting, emit a considerable quantity of blood. We find clear descriptions of this disease in writers, though, before the publication of

Mr. John Bell's Principles of Surgery, it was not classed with aneurisms. Thus, Desault has recorded a case of this affection for the express purpose of proving that pulsation is an uncertain sign of the existence of an aneurism.

The aneurism from anastomosis often affects adults, increasing from an appearance like that of a mere speck, or pimple, to a formidable disease, and being composed of a mutual enlargement of the smaller arteries and veins. The disease originates from some accidental cause; is marked by a perpetual throbbing; grows slowly, but uncontrollably; and is rather irritated than checked by compression. The throbbing is at first indistinct, but when the tumor is perfectly formed the pulsation is very manifest. Every exertion makes the throbbing more evident. The occasional turgid states of the tumor produce sacs of blood in the cellular substance, or dilated veins, and these sacs form little tender, livid, very thin points, which burst from time to time, and then, like other aneurisms, this one bleeds so profusely as to induce extreme weakness.

'This aneurism,' observes Mr. John Bell, 'is a mere congeries of active vessels, which will not be cured by opening it; all attempts to obliterate the disease with caustics have proved unsuccessful, nor does the interrupting of particular vessels, which lead to it, affect the tumor; the whole group of vessels must be extirpated. In varicose veins, or in aneurisms of individual arteries, or in extravasations of blood, such as that produced under the scalp from blows upon the temporal artery, or in those aneurisms produced in schoolboys by pulling the hair, and also in those bloody effusions, from blows on the head, which have a distinct pulsation, the process of cutting up the varix enables you to obliterate the vessel and perform an easy cure. But in this enlargement of innumerable small vessels, in this aneurism by anastomosis, the rule is 'not to cut into, but to cut it out.' These purple and ill-looking tumors, because they are large, beating, painful, covered with scabs, and bleeding, like a cancer in the last stage of ulceration, have been but too often pronounced cancers! incurable bleeding cancers! and the remarks which I have made, while they tend in some measure to explain the nature and consequences of the disease, will remind you of various unhappy cases, where either partial incisions only had been practised, or the patient left entirely to his fate.'

SECT. III.—DISEASES OF VEINS.

1. *Inflammation* is generally the consequence of injury, though it is sometimes idiopathic as in the phlegmasia dolens. When it happens from wounds it is always acute, the inflammation extending in both directions from the wound, but is most severe towards the heart. There is violent constitutional disturbance, and if the disease run into suppuration in large veins it is accompanied by the worst symptoms of typhus, and the patient dies; but, when it ends more favorably, it is by effusion of lymph obliterating the vein.

Treatment must be the same as for other inflammations, but we must be cautious of bleed

ing if the disease originates from that, and employ leeches repeatedly, &c.

2. *Varicose veins* occur mostly in tall persons or pregnant women, or when the blood meets with any obstruction in its way to the heart. They are caused by an over-distension of the vein, so that the valves cease to act, and are either absorbed or thickened, producing a swelled and knotted appearance and feel of the veins, whose coats now become thicker to support the column of blood instead of the valves giving the veins a cartilaginous feel. There is no pain at first, but after some time the veins become more distended, lengthened, coiled up, and tortuous, and the patient feels first an itching, then a heavy numbness, and sometimes a very acute pain, and in many cases the limb becomes œdematous. Strings of coagulable lymph are now effused into the veins, and in a few instances have even caused obliteration, or at other times the blood becomes coagulated in the veins when they are hard to the feel, and often inflame and ulcerate. The ulcers are generally oval shaped in the direction of the veins; very painful; and have an ichorous discharge. Their color is dark blue when the patient is standing; of a livid red when lying down, and they are liable to bleed. In cases where there is no coagulation they sometimes burst and bleed alarmingly.

Treatment.—Put the limb into the horizontal posture, apply a bandage or laced stocking; if there is much pain apply cold lotions or blisters. When there are ulcers, heal them by pressure and sticking-plaster. When a particular cluster gives pain by pressing on a nerve, or hinders an ulcer from healing, we should cut them across with a convex bistoury, sharp at the convex side, which is to be introduced under the skin at a little distance, keeping the instrument flat; then, when it is over the veins, the cutting edge is to be turned towards them, and divides them as the instrument is withdrawn. Thus we have a valvular opening, which heals more readily, and is not so liable to inflammation. This is a much preferable operation to the old one of tying the vein, which was very dangerous.

SECT. IV.—DISEASES OF NERVES.

1. *Tic douloureux* is a most painful disorder, existing in the nerves of the face, especially the divisions of the fifth pair; but it is found occasionally in other parts of the body. The cause of this malady is quite unknown: in a few instances it has depended on a diseased state of the nerve itself either within or without the cranium, but in most cases nothing can be discovered. It generally attacks adults, and seems a disease of debility. The symptoms come on gradually, beginning at first with a slight pain, which increases progressively, till it becomes suddenly intolerable, making the patient scream with agony. It is at first limited, but soon extends over the whole face. The pain, however, is not permanent, but occurs in paroxysms, which last only for a few minutes at a time, but return several times a day, being brought on by any mental emotion, any sudden draught of air upon the face, &c. It is the peculiarity of all nervous pains that they cease when the person is asleep.

These pains do not necessarily impair the patient's health, and they often recover.

Treatment.—We must first ascertain that the disease is not produced by a deranged state of health; if it be we must direct our attention to that; but, if not, we should give tonics, as carbonate of iron, arsenic, bark, &c. In some instances large bleedings have cured the disease, but are not to be relied on. If these remedies fail, we may give the patient a temporary state of ease by dividing the nerve at its exit from the skull into the face, simply cutting it across with a bistoury or scalpel.

2. *Nervous pains* frequently affect persons with disordered digestive organs, as described by Mr Abernethy in his treatise, and may be cured by attending to this circumstance; but they may exist independently, in which case we should give tonics, and apply a belladonna plaster to the part affected.

SECT. V.—VISCERA

URINARY AND GENITAL ORGANS. 1. *Testicle inflammation*, when idiopathic, is generally acute. There is much swelling, retaining the oval shape of the testicle; and it is very much hardened, with a painful feel of tension, even producing sickness. The pains often extend along the course of the spermatic chord to the loins, generally accompanied by symptomatic fever. It seldom goes on to suppuration.

Treatment is the same as that recommended to inflamed testicle from gonorrhœa.

Chronic inflammation may be merely a sequel of the acute, or come on spontaneously. It is generally met with in persons whose health has been previously impaired.

Its first symptom is a dull pain in the back and loins, extending towards the testicle; then, shortly after a pain is felt in the testes itself; then a swelling occurs, being at first irregular and knobby, but afterwards becomes oval; then if the disease be not checked, an abscess forms secreting a yellow cheesy matter, and, when it bursts, a fungus protrudes, which looks like the body of the testicle, sometimes covered by granulations, and having this cheesy matter on its inner side.

Treatment.—Put the system gently under the influence of mercury, either by calomel and opium, or the oxymercurate, or by rubbing mercurial ointment with camphor into the part. This must be continued for five or six weeks; but, if the disease arise from syphilis, or the previous exhibition of mercury, we should then give only very small doses, combined with the use of sarsaparilla. If an abscess forms, and sprouts out, we must sprinkle the surface with red precipitate, and keep the patient in bed; and, when it begins to granulate, dress it with some stimulant application.

There is another chronic enlargement, which arises from the irritation of a stricture in the urethra; the cure of which is therefore obvious, viz. to cure the stricture; but if it does not then subside we must give mercury for it as for the former.

Schirrus testicle is not of common occurrence, but when it does appear it is first in the body of

the testicle, producing a hard swelling which feels like a marble body in the scrotum, and is irregular and knobbed on the surface. It is attended with severe pain, which becomes more intolerable as the complaint advances. It next attacks the epididymis, and spreads up the spermatic cord, which becomes enlarged and tuberculated. In true scirrhus the testicle itself does not grow to any considerable size.

Treatment.—The only remedy for this disease is extirpation, which must be performed before the neighbouring glands become contaminated, if we wish for success, as otherwise the disease is sure to return. Incision of the testicle is to be performed in the following manner:—

This is one of the most simple operations in surgery; but, before it is undertaken, be cautious that the disease does actually require to be removed, and particularly bear in mind the circumstances which should regulate its removal.

You grasp the testicle in your left hand; begin your incision at the upper part of the abdominal ring, and extend it to the lower extremity of the testicle. Lay bare the spermatic cord completely at the abdominal ring; and put a needle and ligature through it and the artery of the vas deferens. Having divided the cord, you draw it towards you, and detach the cellular membrane behind it: in this consists the whole of the operation. The spermatic artery, the artery of the vas deferens, and several in the scrotum, are the vessels which require securing.

In making your first incision, you must not leave any part of the scrotum undivided; for, if it is not carried to the lower part, a bag of matter will form, and the healing process be thus prevented.

Fungus Hamatodes.—This disease is much more common than the last; it begins, like true scirrhus, in the body of the testicles; but, unlike that disease, it almost immediately affects the whole body of the testicle at its first commencement.

In a very short time, the epididymis becomes affected; next the spermatic cord; and, in the course of a very few weeks, a tumor forms in the loins. The disease is at first unattended with pain; but, when the spermatic cord and the tumor in the loins become of great magnitude, the patient suffers considerably.

The fungoid swelling of the testicles sometimes increases to the weight of several pounds; and usually occurs between the age of seventeen and thirty-five.

The appearance of the surface is somewhat livid; the spermatic cord is loaded with blood, and in some parts you may feel a fluctuation, as if there was a cyst within it: it also becomes covered with tubercles of considerable size.

The tumor has a soft pulpy feel, readily yielding to pressure; and, on the first examination, you might suppose the disease to be hydrocele.

It may be distinguished from hydrocele in the following manner:—in the first place, it is flattened on the fore part, whereas in hydrocele it is pyriform; if you squeeze any of the fungoid tumor, the patient will complain of the pain arising from the compression of the testicles, which he will not do in hydrocele, unless you

squeeze the posterior part of it: the fungoid tumor rather yields to the pressure of the finger than fluctuates from one side to the other, as in hydrocele; and, lastly, the great weight of the swelling when you lift up the sides, and the livid appearance of the scrotum, mark the malignant characters of this disease. The treatment is the same as for scirrhus.

Varicocele, or varicose veins of the spermatic cord, are most common in persons of costive habit of body, and occur more frequently on the left side. They are sometimes annoying from the pain which they create, or, what is worse, from an absorption of the testis on that side. They may be mitigated by wearing a suspensory bandage, blistering over them, and keeping the bowels open. They are sometimes liable to be mistaken for rupture, but may be distinguished thus:—make the patient lie down and the tumor will subside on pressure upwards; but on continuing the pressure, reappears, which a hernia does not.

Hydrocele may exist in two forms, first in the tunica vaginalis; second, in the spermatic cord.

Tunica vaginalis has two varieties, the common and congenital. The common may occur in consequence of a slight inflammation, or without being traceable to any cause.

Symptoms.—The symptoms of this complaint are, a colorless, smooth, roundish, pyriform, sometimes oblong swelling, which slowly and gradually extends upward from the lower part of the scrotum. The tumor does not disappear on pressure. At first, it is soft and fluctuating; and, on the fingers being removed, it immediately rises to its former level. The swelling cannot be diminished, nor pushed into the cavity of the abdomen, by any artifice of the surgeon. When the disease is more advanced, and has attained a larger size, the tumor becomes oblong, heavy, and hard, though much less so than in the case of an enlarged testicle. At the same time, the fluctuation grows less distinct. If the fluid contained in the tunica vaginalis be clear, this membrane not much thickened, and a candle be placed behind the tumor, the scrotum has a semi-transparent appearance. At last the hydrocele so conceals the testicle that this body can only be distinguished, at the upper and back part of the tumor, by a certain hard feel. The spermatic cord, however, is still quite obvious to the touch. Though the swelling may have acquired its greatest size, and the scrotum be considerably distended, the corrugations of the latter part are seldom so obliterated as in the anasarous hydrocele. The penis seems small, and, as it were, sunk in the tumor. The integuments of the scrotum also acquire an increased thickness; the veins appear large, and there is rather a sense of elasticity than of fluctuation, communicated to the surgeon's fingers. The spermatic cord itself even becomes somewhat concealed, when the hydrocele has ascended very far. In these cases, the tunica vaginalis always becomes more and more thickened, which change is common to all membranes, when they are long distended.

Treatment.—In young persons we may endeavour to obtain an absorption of the fluid by

using a suspensory bandage for the scrotum, and giving internal remedies, as calomel, scammony, and jalap; at the same time applying discutient lotions. But this often fails, and when it does, we must either adopt a palliative or radical treatment; the palliative consists in merely introducing a trocar and canula, and so drawing off the water, which may be required to be done usually once in six months, but in some cases in one, two, or three months. In performing this operation we must remember the situation of the testicle, to avoid wounding it; it is at the posterior part two-thirds of the way downwards. The radical cure may be performed by causing the inner surfaces of the hydrocele to adhere, by inflammation and effusion of lymph; or we may make an incision into the tumor, and heal it by granulation. This last is preferable when we suspect a diseased state of the testicle itself, but should not be attempted in old persons, as in them it often produces very violent symptoms. To produce adhesions there are commonly two ways employed, one the passage of a seton through the tumor, which is preferable in young people, though more tedious, as it generally requires ten or fourteen days. This was the method recommended by Mr. Pott. The other, and commonly the best manner, is by injecting the cavity with a stimulating fluid, and is generally performed thus:—a common trocar and canula is introduced, the water is drawn off, and an India rubber bottle, filled with injection, and provided with a tube and stopcock, is now fixed into the canula; the contents emptied into the sac by pressure, and the stopcock closed till the patient feels an uneasy sensation or pain in the loins, which generally happens in about four or five minutes. The bottle is now to be taken away, and the stopcock turned so that the injected fluid may run out. The patient must then be kept quiet for some days. Care must be taken in this operation that the fluid is injected into the sac and not the cellular membrane of the scrotum, as in that case sloughing must take place, endangering the patient's life.

Congenital hydrocele occurs in those children whose tunica vaginalis remains open from their birth, communicating with the cavity of the abdomen, and in which the serous secretion of the peritoneum is accumulated by gravitation. These hydroceles may be distinguished from common ones by our being able to empty the fluid from the sac into the abdomen by pressure.

Treatment.—The patient should wear a truss to prevent the formation of a rupture, and close the passage from the abdomen, which it does by the formation of adhesions, through the pressure and the communication being stopped; the effused fluid will be absorbed, if the patient be in good health; but if the swelling does not diminish it causes wasting of the testicle, or other inconvenience; then we may inject the tumor, taking care to prevent the passage of any portion into the abdomen by pressure on the abdominal ring. This was recommended and practised successfully by Desault; for it does not produce universal inflammation of the peritoneum as was apprehended.

Encysted hydroceles may occur between the tunica vaginalis and albuginea, or in the sper-

matic cord; in the former case the testicle feels like a double one; there is no pain; the latter is also not painful, and is oval shaped. It is likely to be mistaken for hernia, but is distinguished from it by its semitransparent appearance, by its not being able to be returned into the abdomen, and by the edge between it and the latter being well defined.

Treatment.—In boys they may generally be dispersed by stimulant lotions; but this is not the case with adults, in whom they may be injected when of large size; but when small should be laid open and dressed to the bottom with lint or flour.

Hæmatocele.—This signifies a swelling of the scrotum, or spermatic cord, occasioned by blood. The disease is of four kinds, two of which have their seat in the tunica vaginalis; one within the albuginea, and the fourth in the membrane investing the spermatic vessels.

1. In letting out the water of a hydrocele a vessel is sometimes wounded. After the operation, the blood insinuates itself partly into the tunica vaginalis, and partly into the cellular substance of the scrotum, so as to form in a very short time a tumor nearly equal in size to the original hydrocele. The blood colors the fluid of the hydrocele, when it is flowing through the canula.

2. Another species is when the blood is effused in consequence of a spontaneous rupture of a vessel after the operation, and it is entirely confined to the cavity of the tunica vaginalis. The fluid of the hydrocele is not tinged with blood, when discharged.

3. In the third kind of hæmatocele, the blood is extravasated within the tunica albuginea, from the vessels of the glandular part of the testicle.

4. The fourth arises from a rupture of a branch of the spermatic vein.

Treatment.—The first two cases may generally be cured by opening the cavity of the tunica vaginalis, removing the effused blood, and applying dry lint to the inside of the membrane. If the quantity of blood were very small, discutients might disperse it, and do away all necessity for operating.

The two other cases are less frequent. The third arises from a morbid state of the substance of the testicle, and can only be cured by castration.

The last species of hæmatocele, or that arising from a rupture of the spermatic vein, is generally caused by great or sudden exertions, contusions, &c.

When the case is clearly distinguished from a hernia, attempts must be made to promote the absorption of the extravasated blood, by applying to the tumor the sal ammoniac lotion, or even camphorated liniments. About twice a week, a purgative should also be exhibited.

If the case should obstinately resist such treatment, a thing which can hardly occur, an incision must be made into the tumor, and, the bleeding point being discovered, it should either be tied, or stopped with a dossil of lint.

2. *Diseases of the penis.*—The penis is subject to a variety of herpes, called herpes preputii. It is of consequence to recognise this, as it may else be mistaken for chancre. Its appearances are first two or three little vesicles, or one large

one, which soon become pustules; these break about the fourth or fifth day, and leave little ulcers, which have a white base, and a slightly elevated edge; and, if any escharotic be applied, it leaves a hard base like a true chancre. In treating it we should avoid all stimulating applications at first; and, if they do not heal, we may then touch with the nitrate of silver.

The penis is also liable to be attacked by cancer, which must be treated as other cancerous diseases; but there is one variety which deserves notice, this is

Cancer scroti.—The peculiar and distinguishing character of this disease from common cancer is, that it is nearly or entirely unaccompanied by pain. It is a disease which always makes its first attack on, and its first appearance in, the inferior part of the scrotum; where it produces a superficial, painful, ragged, ill-looking sore, with hard and rising edges: the trade call it the soot-wart. I never saw it under the age of puberty, which is, I suppose, one reason why it is generally taken, both by patient and surgeon, for venereal, and, being treated with mercurials, is thereby soon and much exasperated: in no great length of time, it pervades the skin, dartos, and membranes of the scrotum, and seizes the testicle, which it enlarges, hardens, and renders truly and thoroughly distempered; whence it makes its way up the spermatic process into the abdomen, most frequently indurating and spoiling the inguinal glands: when arrived within the abdomen, it affects some of the viscera, and then very soon becomes painfully destructive. The only plan of treating this dreadful malady is by extirpating it before the ulceration has attained any considerable magnitude.

3. *Stricture of the urethra* sometimes exists at the orifice caused by recent ulceration and cicatrisation. This must be dilated with a bistoury, and then a piece of bougie must be constantly worn till it heals over it. Other strictures mostly take place on the membranous portion of the urethra, and may be produced by a thickened state of the membrane itself, or a mere chasm of the surrounding muscles, or by a union of both, which is most common. But a spasmodic stricture will lay the foundation of a permanent one, and permanent strictures vary very much; for one day it produces a great deal of distress, but another the patient is scarcely sensible of the disease. The symptoms of a permanent stricture are often liable to be mistaken for those of a gonorrhœa, there being difficulty in making water, sometimes pain, with a divided or fine stream, and discharge of mucus from the urethra. Then the bladder becomes irritable in proportion to the resistance the stricture offers. So that when we wish to ascertain what the disease is, we must pass a full sized bougie (as a smaller might be caught by the lacuna) which, if there be a stricture, will be stopped by it. Then we may try to pass a metal sound. If a stricture be neglected the bladder becomes inflamed, and so irritable that it will not hold an ounce of urine, secreting a thick ropy mucus, which clogs up the passage. Sometimes from the effort of straining, sacculi are formed in the bladder, which grow larger and larger; and if

the patient is subject to stone, these form receptacles for them. When there is great difficulty of passing the urine, the bladder becomes constantly distended; then the ureters become dilated, and the urine accumulating, the pressure is continued up to the glandular stricture of the kidneys, causing it to be absorbed; but urine is still secreted by the cortical part. It is generally accompanied by pain in the loins, and the constitution is generally affected. In permanent stricture an abscess often forms in the perineum behind the stricture, accompanied with much constitutional disturbance, the fever being inflammatory, if no urine finds its way to it, but more commonly there is a communication behind the stricture with the urethra, in which case the fever assumes a typhoid appearance, till the abscess bursts or is opened; which should be done as soon as the complaint is detected. Then the abscess is kept open by the constant dribbling of urine through the wound, round which is generally a little fungous growth, forming a fistula in perineo.

Treatment of stricture.—This consists in dilating it gradually, by the long continued use of bougies or catheters. Bougies generally give least irritation, when made of wax or plaster, but in old cartilaginous strictures, whose absorption we wish to promote by pressure, we should employ metallic ones; or, if they are very inveterate and contracted, we may destroy them by bougies, armed with nitrate of silver. A small bougie only can be passed at first, but the size may be afterwards gradually increased. If the passage of a bougie in a recent stricture gives much pain, or causes bleeding, we should omit its use for some days.

In passing all instruments into the urethra, we should be cautious of using violence, as the instrument may then be pushed through the urethra between the bladder and rectum, making what is called a false passage, and is known by the want of urine following it, in which case we should endeavour to find the true one, and keep a catheter in the urethra till the wound has healed. In cases where there is violent pain and irritation in the urethra, we should not attempt to pass an instrument, but bleed the patient and give him sedatives. When there is a spasmodic stricture, it may generally be relieved by the bougie aided by sedatives or the warm bath.

In cases of fistula in perineo, we should endeavour to pass instruments through the stricture; in which, if we succeed, the wound will probably heal, but in many cases this is impossible, even a probe not being admitted into the stricture. In this case we should cut down across the stricture, previously introducing a probe into it if possible; if not, we must be guided by our anatomical knowledge. Having divided the stricture, we should pass a catheter into the bladder, and heal the stricture over it.

4. *Bladder.*—Chronic inflammation. When this exists, which is not uncommon in old persons, there is a constant desire to make water, and pain after making it; the urine deposits a thick ropy mucus; it is often accompanied by febrile symptoms; the patient's countenance looks anxious, and he has a urinous smell.

Treatment.—Cup on the loins or perineum, or apply leeches; keep the patient quiet, give him opiate suppositories every night, and warm water injections to bring them away in the morning. The best medicines are uva urie; small doses of Cubeb's mercurials, or balsam of copaiba. It is seldom that we succeed in curing the disease, but these remedies mitigate it considerably.

Calculus.—This complaint may exist in two states: 1. Gravel in the urine; 2. Stone in the bladder.

Gravel may be of two sorts; the lithic acid, which is of a yellow color, or phosphate of ammonia and magnesia, which is of a whiter color. It produces a frequent desire to make water, blood sometimes accompanying it, and pain in the urethra.

Treatment.—Attend to the state of the general health, and if acid prevail in the urine, give a dose of calomel and rhubarb occasionally, with alkalies constantly. Let the patient avoid all acid substances, and take a vegetable diet. When the alkali prevails, give acids, as the citric or muriatic.

Calculi of three sorts are formed in the kidney. 1. Lithic acid; 2. The triple phosphates; 3. Oxalate of lime, or mulberry calculus; when the latter are voided, the disease is not likely to return, but the two former may always recur. A calculus in the kidney keeps on increasing in size, dilating the pelvis, and causing abscess; also pain in the kidney and outside the hip, which is very intolerable. These symptoms may be relieved, but not cured, by alkalies, which hinder the growth of the calculus, keep the urine only a little acid; when calculi descend into the ureters, they cause pain there and in the testicle, and after a time it becomes swollen and hard; but when they drop into the bladder the pain suddenly ceases, but the bladder becomes a little irritated. If they be very small they may pass through the urethra; but, if not so, they may lodge in it, causing retention of urine. For this the patient must use a warm bath, have an opium glyster, and then a strong purgative, which may make it pass more easily; or, it may, if small enough, be extracted by forceps made for the purpose; or this plan will sometimes answer: give the patient diluent, and diuretic drinks, after dilating the urethra for a fortnight, then let him keep a bougie in the passage as long as he can possibly bear the distended state of his bladder, and, when it is withdrawn, the calculus may be forced out by the gush of urine.

Stone in the bladder may arise from any substance lodging in the bladder, and forming a nucleus, round which fresh matter is deposited. The most common cause is a kidney calculus. Children and old men, with diseased prostate gland, are most liable to it. It is composed generally of lithic acid, but sometimes of the triple phosphate of ammonia and magnesia, or the oxalate of lime. In general a small stone produces no serious inconvenience except in diseased bladders; but, when of larger size, there is a pain in the glans penis, sometimes dull, sometimes burning, with pain in the bladder. Frequent desire to make water, coming on suddenly when the patient moves; after having

made water, the pain becomes more severe, often excruciating. There is mostly blood in the urine at some time or other, often whilst making water the stream suddenly ceases, or the patient at times can only make water in one position. The sediment is a reddish mucus. These symptoms are all produced by the rough substance irritating the sensitive neck of the bladder; so that when there is an enlarged prostate, the symptoms are less violent. When a stone is very large, it presses on the rectum and causes pain, or piles, or frequent desire to void the fæces, when in reality the gut is empty. Stone often produces an inflammation of the bladder, and even of the kidneys, and sometimes ulceration of the bladder.

Treatment.—Stone may be hindered by proper remedies from growing larger, but by no plan hitherto proposed can it be dissolved when once formed, so that our only remedy is to remove it by an operation, except where the general health is bad, or there exists some other disease in the bladder. The pain may be relieved by an horizontal position, opiate glysters. When the bladder is diseased give demulcent drinks, and small doses of copaiba or culules. Females should seldom be operated on, as the urethra may in general be sufficiently dilated to admit of its extraction. An instrument has been invented for this purpose by Mr. Weiss.

5. *Acute inflammation of the prostate gland.*—This complaint is not confined, like the chronic enlargement, to late periods of life, but attacks persons of any age, and generally terminates in suppuration. The most prominent symptom which characterises this complaint is violent pain immediately after discharging the urine, and in this respect the disease resembles stone. As the inflammation advances, an abscess will be produced in the gland, and retention of urine the consequence.

Our treatment, in this case, must consist of blood-letting, and administering mild laxatives, together with antimonial medicines. The catheter it is also necessary should be used. We therefore pass a common catheter, and about the fourth day you will perceive that matter escapes through it; so that this, coupled with other circumstances, stamps the nature of the complaint. Rigors do not attend the formation of this matter.

Chronic inflammation, or enlargement of the prostate gland. This is the consequence of age, and not of disease; and is characterised by a number of symptoms sufficiently particular to distinguish it from stone. In these cases there is sometimes partial retention of urine; the patient is a long time voiding his urine, which has a particularly powerful smell, arising from its being ammoniated in consequence of its long continuance in the bladder. The next symptoms observable are pain and numbness in the glans penis; the prepuce not possessing its usual sensibility; there is a sense of weight and uneasiness in the perineum, relieved by pressure with the finger; pain in the back of one or both thighs, in the loins, and at the origin of the sciatic nerve, and course of the ureters; and the fæces are flattened from the pressure which is

made upon the rectum by the swollen gland. The urine finally acquires a highly offensive ammoniacal smell, and at length becomes white or milky, and, when long retained, brown, and even bloody.

If the enlargement of the prostate gland continues to proceed for a length of time, it will, in many cases, occasion a complete retention of urine.

Treatment of enlarged prostate.—Your object of treatment may be to endeavour to act upon the gland, by means of small doses of the oxy-muriate of mercury, when the enlargement is the only complaint; but, if there is retention, you must relieve this symptom, and afterwards guard against its return. When no urine passes whatever, and when there is great pain at the neck of the bladder, you should take away blood from the arm, apply leeches to the perinæum, administer purgatives, and put the patient into a warm bath. If these means should succeed in procuring relief, the best medicine that can afterwards be given for the purpose of preventing a return of the retention, and, at the same time of lessening the inconvenience which sometimes attends the complaint, is composed of fifteen drops of the liquor potassæ, five drops of the balsamum copaibæ, and an ounce and a half of the mistura camphoræ. This is the best medicine you can use; it will afford considerable relief, which is all that you can expect; for you must not dream of making a cure.

When you are called upon to relieve retention of urine, from enlarged prostate, by the introduction of a catheter, the instrument should be fourteen inches in length, and a quarter of an inch in diameter. In consequence of the pressure within, a broad instrument will answer better than a narrow one, but, being bulbous at the end, it will readily ride over the enlargement.

When the difficulty of introducing the catheter is great, it is better to leave it in the bladder.

Retention of urine may arise from two causes: 1. Spasmodic stricture. 2. Diseased prostate gland. The former then is the case with young, the latter with old persons; this must be treated as recommended in diseased prostate. Spasmodic stricture generally occurs after a fit of intemperance and drunkenness, and is generally so complete that with all his efforts, the patient can barely squeeze out a single drop of urine. He becomes alarmed, his pulse rises, the bladder becomes more and more distended, and the patient's efforts proportionally increased. The countenance becomes anxious, the pain of the bladder excessive; but after the patient has been in this state for two days, or a little more, the pain abates, and a few drops of urine begin to flow. The sufferer now flatters himself that he shall be soon relieved, as he finds his clothes wet with urine; but this dribbling is caused by the full and violent distension of the bladder, which, not being able to hold another drop, forces out, by its tension, the urine which continues to be secreted by the kidneys. In a short time after this the patient feels something give way, or else feels himself suddenly relieved, and now thinks in earnest that he is well; but is miserably de-

ccived. The bladder, from a continued state of inflammation, has sloughed, forming a round aperture in the perineum, into which the urine cannot flow for its dense fascia, but makes its appearance in the cellular membrane of the scrotum, penis, and above the pubis, and, if he be not relieved, the patient dies of the mortification of these parts.

Treatment.—In the early stage we must try to introduce a very small catheter or bougie without using violence, for that will aggravate matters. If we cannot succeed, we must put in practice every method for overcoming spasm, such as by the warm bath, particularly opium glysters, which succeed in nine cases out of ten. Doses of tinct. ferri. muriatis, as recommended by Mr. Cline, and the tobacco glyster. If these fail we may try a bougie armed with linen caustic, which will sometimes succeed; but if all fail we must then have recourse to puncturing the bladder.

Puncturing the bladder.—The operation of puncturing the bladder above the pubes is very simple, and is founded on the following anatomical circumstances:—in the natural formation of the parts, the peritonæum falls from the inner side of the rectus, over the upper part of the bladder, and is reflected backwards to the fundus, leaving a space filled with cellular tissue, between the pubes and the reflected peritonæum. This is the space in which the operation is performed, and all that is required, is to make your incision through the integuments, to the extent of an inch above the pubes. It is best to open the integuments in the first instance, because the trocar will afterwards enter the bladder with more ease, and because, if there should be any extravasation of urine by the side of the instrument, it will more readily escape. The incision should extend as far as the linea alba. With respect to the direction in which the trocar is to be passed, you must not, on any account, direct the point downwards towards the anus, but obliquely from the penis to the back of the pelvis, just towards the basis of the sacrum. The trocar and canula being introduced, the water passes through the canula; and an elastic gum catheter should be introduced through the canula, and may be left in the bladder for a great length of time without producing any injurious consequences.

In the female it is absolutely necessary this operation should be performed in cases of retention of urine, from retroverio uteri, and from a cancerous disease affecting the meatus urinarius. Operating through the vagina ought never to be performed.

Operation through the rectum.—This operation is performed in the triangular space formed by the meeting of the vasa deferentia, constituting the apex; the sides from the vasa deferentia as they diverge in their passage backwards; and the basis of the triangle, by the peritoneum, as it is reflected from the posterior part of the bladder to the upper part of the rectum. When you pass your finger into the rectum, you will feel the bladder projecting into it. It is elastic, and yields with difficulty to the pressure of the finger; you will readily feel the fluctuation.

This leads you to the spot where the trocar is to be introduced; the triangular space above-mentioned is directly presented to the point of the instrument. You introduce your finger about an inch (never less than half an inch) behind the prostate gland, and then upon the upper part of the finger pass the trocar, which may be either curved or straight, to the posterior part of the bladder. When the point of the instrument rests upon the upper part of the rectum and the posterior part of the bladder, you pass the trocar into the bladder obliquely upwards and forwards by a slight and sudden motion of the hand. An elastic gum catheter is then to be employed. On the whole, however, though an easy operation, there are many objections, and I would not recommend it to be performed.

But Sir A. Cooper says, In cases of accumulation of urine in the bladder, for which many would have recourse to puncturing that organ, I have found opening the urethra only, a better and safer course. All I do is this, I desire the patient to draw up his legs as if he was going to be operated on for stone; I then make my incision into the urethra, according to the seat of the stricture, and the result is, that the urine is passed by the perinæum, and the bladder is relieved, without being in the slightest degree injured.

If we are not called to the patient before the bladder has given way, we must make an incision into the urethra, through or behind the stricture, and scarify the swollen parts freely to let out the urine and sloughs; then we must apply poultices to promote their separation, and when the wounds begin to look clean, dress them.

6. *Rectum*.—Piles are caused by varicose veins of the rectum; they are situated either above or below the splenic muscle, but not on it. When they are situated externally, they often swell and inflame, becoming very troublesome; but, when internally, they produce first an itching of the rectum and scrotum, then a sensation of some foreign body in the rectum, which subsides and returns alternately; then when at stool the patient notices something protruding, which becomes more and more every time; they will return spontaneously at first, but presently the patient is obliged to press on them; and at length it is with great difficulty and length of time, that he can get them up at all; now there is a great discharge of mucous; pain when they protrude; they inflame and often bleed profusely; the patient becomes pale and feeble, and has a voracious appetite; they often lay the foundation of a prolapsus ani, and at last they make large fleshy tumors, which ulcerate, or form abscesses, causing fistula in ano.

Treatment.—Keep the bowels moderately open; when they are in a mild form, wash them with cold water, and inject this every morning after a stool. If they are more severe, add to the injection alum, or a muriated tincture of iron, and give the patient Ward's paste. If they are very severe, and bleed, we may remove them by an operation. If seated externally they may be snipped off with knife-edged scissors; but this is not safe where they are internal, on account of the profuse hæmorrhage. These are to be tied

thus:—The patient must be made to sit over warm water, and strain; and when the piles come down, run a needle, armed with a double ligature, through them, and tie one on each side tightly round the base. This is not very painful and soon sloughs away.

Fistula in ano.—This name has been improperly applied to all abscesses about the rectum, but it is only applicable to those which do not heal but leave a sinus, lined with a cartilaginous matter and secreting not pus but ichor. These sinuses may or may not communicate with the rectum, and can generally only be cured by an operation.

Treatment.—It is of great importance to give such medicines as will bring the fistula into a healthy state. With this view the balsam of copaiba may be given with great advantage; if there is much irritation give soda, which has great efficacy in diminishing the irritability of the rectum. Aromatic medicines should be given, especially the confectio piperis nigri of the London Pharmacopœia. This medicine in a very short time brings the fistula into a healing state; healthy granulations arise from the surface, and the discharge, instead of being serous or bloody, consists of good pus. Submuriate of mercury, with saline purges, should be occasionally given during the use of aromatics, with a view of promoting the secretion of the liver and intestines. The operation of dividing the sphincter ani is simply in proportion as you find a ready opening into the rectum. You introduce a small probe-pointed bistoury into the fistula, pass your finger up the rectum to meet the instrument, and, carrying the point downwards, divide the intervening parts. If the fistula is very extensive, you will be under the necessity of putting your finger on the extremity of the instrument, drawing the knife downwards. If the fistula does not open into the rectum to meet the knife, place it along the end of the knife, and move the rectum for some little time with your finger nail, and then, cutting through the cellular tissue, bring the point of the instrument into the rectum. A very copious bleeding generally follows the division of the intestine; you must not, therefore, leave your patient, but endeavour to stop the hæmorrhage by introducing a portion of lint into the wound. No union of the sphincter ani will take place until granulations have arisen at the parts of the wound most distant from the rectum. You should not change the lint for several days, but apply poultices, and merely introduce a probe from day to day, to see that there is no improper adhesion.

Ulcers of the rectum, give the patient a great deal of pain and mental anxiety; causing an unpleasant discharge and a gradual decay of the health. They may often be cured by mild laxatives, then stimuli, as copaiba, cubebs, or Ward's paste; but when they do not heal it is generally owing to their being constantly agitated by the splenic muscle; so that division of this, in a backward direction, will accomplish the cure.

Prolapsus ani is common in children of costive habit; in whom purgative medicines alone will generally succeed in removing it; but if not we may support the rectum by a compress and use

of astringent injections. In adults, it generally depends upon internal piles, upon the cure of which the disease ceases.

SECT. VI.—DISEASES OF THE SKIN.

1. *Œdema* is a preternatural accumulation of aqueous fluid in the interstices of the cellular substance of a part. The tumor is uncircumscribed. The skin of the swollen part retains its natural color: if at all changed it is rather paler. The part has a cold feel, and the pressure of the finger occasions an impression, or pitting, which remains some time, and disappears slowly. There is no acute pain; but there is an uneasiness or sense of weight, and tightness. When the œdematous limb is in a depending posture, the magnitude of the tumor is increased, et vice versa.

Œdema may depend on constitutional, or on local debility. Contusions, sprains, the long-continued use of relaxing poultices, and washes, are often local causes of œdema. A part which has undergone acute inflammation often remains œdematous for some time afterwards. In all these instances the tone of the vessels being impaired is the cause of the disease. The complaint is very often owing to some impediment, preventing a return of blood to the heart. The pressure of the gravid uterus on the iliac veins often renders the lower extremities œdematous. Aneurisms frequently compress the chief veins of an extremity, and bring on this affection. Œdema must frequently be a mere symptom of other diseases, which operate as a cause. It accompanies ascites, hydrothorax, deeply seated abscesses, &c.

Treatment.—No cure can be expected till the particular cause has been removed. To promote the absorption of the extravasated fluid, and to re-establish the original tone of the vessels, are always, however, grand indications. The limb should be kept in an horizontal position. Frictions made on the part with flannel, fumigated with aromatic vapors; the application of camomile flowers, and preparations containing camphor; and a moderately tight roller; tend strongly to rouse the absorbents into action. The operation of these means is considerably assisted, by giving internally purgatives, diuretics, and emetics. If the tumour should not soften under this plan, but become so tense as to occasion pain, inflammation, and the danger of gangrene, the fluid may be discharged by means of small punctures. These, however, are not void of danger; for all wounds, in dropsical constitutions, and parts, easily become gangrenous. The punctures, therefore should be as small as possible. It is chiefly, however, in cases of anasarca, or those attended with a general dropsy of the whole body, and an extensive extravasation of water in the cellular substance, that scarifications become necessary, and not for the local swelling, implied by the term œdema.

2 *Boil.*—This does not differ from common abscess, except in containing a small slough at the bottom, which is commonly called the core; this should be squeezed out and it will heal up. Persons are often troubled with a course of them after illnesses; in these cases country air will be serviceable, and a course of liq. potassa or bark, &c.

3. *Carbuncle* occurs in persons of broken down constitution, either from free living or other causes; it may be called a malignant or gangrenous boil. It is always attended by considerable constitutional disturbance. The swelling is not much elevated above the level of the surface of the body, the skin, over the middle of the disease, assumes a dull brown, red color; and, what is always very remarkable, it becomes so hardened and thickened, that, when handled, it feels like brawn. As the complaint advances, several apertures generally form in the tumor. Through these openings, a yellow, greenish, bloody, irritating discharge flows out, while the great mass of the matter, and sloughy cellular membrane, still continues confined, and the gangrenous mischief, in consequence of an early, free opening, not being made, often spreads to such an extent that the patient perishes. Indeed, the ravages attendant on carbuncles are at their deepest part, or their base which always occupies a much greater extent than the superficial portion of the disease.

Treatment.—We must lay them open by a crucial incision, and poultice till the sloughs have separated; then stimulate them. Give the patient cordials and tonics, and, if he have several in succession, sarsaparilla or mercury, with generous diet, country air, and exercise.

4. *Tumors, encysted*, occur mostly in the substance of the skin, and are composed of a cyst, analogous to a serous membrane, which secretes a pulpy cheesy substance, very offensive and rancid. They are situated very commonly in the scalp. They sometimes inflame and burst, leaving a little orifice, from which matter flows and is incrustated, sometimes in the shape of a horn.

Treatment.—It is seldom, if ever, that we can discuss these tumors, but we may check their growth by cold and stimulating lotions; the only cure is by removing them. In doing this we take care to avoid opening the cyst; but, by dissecting round it, turn it out entire, without much difficulty. If we should accidentally wound it we must then take hold of the cyst by a pair of dissecting forceps, and care must be taken not to leave any of it remaining, or else fungus granulations often rise from it, hindering the wound from healing. The wound may otherwise be healed by the first intention.

Fatty tumors are either contained in a fine cyst or not; the former is the most common. It gives the patient no pain but continues to increase. If it gets beyond a certain size it is liable to inflame, and either suppurate or ulcerate.

When it ulcerates, the growth of the tumor is more rapid, and discharges a thin watery pus with flakes of fatty matter floating in it. This may be distinguished from other tumors by the feel, it being soft, elastic, and possessing no fluctuation; they sometimes run into more malignant tumors. The only method of curing these is to dissect them out when they become troublesome. It is generally a very easy operation. We must cut into the middle of them, and can mostly separate them from the surrounding parts by the fingers.

There are several other varieties of tumors, not contained in cysts, and not of malignant nature, such are the sarcomatous or fleshy tumors de-

scribed by Mr. Abernethy. These require the same treatment.

5. *Corns and bunyons* are caused by a laminated induration of the cuticle from constant pressure or friction, and are generally produced on the feet by wearing tight shoes; when the disease is more severe, or in that form which is commonly called bunyons, 'a buva mucosa,' says Mr. Brodie, 'is formed under the part which often inflames, though it seldom ends in abscess, but causes a great deal of pain.'

Treatment.—We may either palliate or radically cure them; the first may be done by causing the patient to wear looser shoes; paring the corn; soaking it in warm water; defending it from pressure by wearing a felt sole with a hole cut to receive the corn, or applying pieces of diachylon plaster spread on leather over the corn, but leaving a little aperture in the middle, which just allows the greater part of the corn to enter; these will generally succeed in quieting them, but when they inflame, we must leech them, and apply cold lotions. If they suppurate they will burst and cure themselves radically; otherwise this may be accomplished by rest, soaking the feet every day, and then paring away as much as possible, till we can dig out the little heart in the middle, or else we may pare it very thin, and then touch it with lunar caustic. Mr. Brodie says they may be cured by blistering.

6. *Whitlow*, is an abscess situated at the root of the nail, very often burrowing under it, causing a great deal of pain and death of the nail. It should be opened as soon as possible, and, if there be matter under the nail, we should let it out by scraping the nail with a piece of glass till it is quite thin, and then slit it up; when the nail dies it acts as a foreign body and irritates the abscess, so we should bring it away as soon as possible.

7. *Warts* have been already mentioned as occurring about the pudenda, the treatment of which will apply to common warts; but these last may be safely removed, by nitric acid or ligature.

8. *Navus.*—These are spots in the skin which have grown with the child, and consist of a plexus of small arteries and veins, which sometimes spontaneously enlarge, and are apt to bleed; if the application of cold does not succeed in checking them, they must be treated as aneurisms by anastomosis which they very much resemble.

SECT. VII.—DISEASES OF GLANDS.

1. *Absorbents.*—Inflammation of these does not differ from common inflammations, except that there are lines seen running from one to the next above it; this is particularly the case on the arm, but this disease is generally caused by extraneous matter, which has already been noticed under the head of *poisoned wounds, and dissecting wounds*. But the most common affection of these glands is the scrofulous affection of them, in which case they proceed to suppurate very slowly; they must be treated as recommended in serofula.

2. *Salivary glands.*—Ranula is a tumor of the sublingual gland, which is very annoying to

the patient, as it hinders the motions of the tongue. It is caused by an obstruction of the duct, so that the saliva accumulates in it, and then becomes inspissated; it is not painful, and may be treated by making an artificial opening into the mouth, either by cutting a piece out or opening the tumor, and preventing it from healing.

3. *Salivary fistula.*—When a salivary gland inflames and suppurates, it may break externally, through which opening, the saliva pours in incredible quantity, so that the patient is constantly annoyed, particularly at meal times; these may be best cured by running a seton through the external opening into the mouth.

4. *Thyroid gland* is liable to scirrhus as well as other glands; but this is very rare, the most common affection of it, being a preternatural growth of its own substance, so that it forms a monstrous tumor in front of the neck; this has been termed goitre, and is very common in mountainous countries; so much so, that in some districts of Switzerland they are considered ornamental; they are more frequent in scrofulous persons. These tumors cannot be removed from the quantity of blood vessels, but they may be diminished or even cured by the exhibition of iodine, internally or externally.

5. *Diseases of the breast.*—This gland is liable to inflame, especially when nursing; it is generally accompanied by acute pain, and mostly ends in suppuration, forming an abscess, which, when deeply seated, breaks by several openings, forming sinuses between them.

Treatment.—The antiphlogistic means must be used the first instance; but, if the pain be violent, warm applications must be used instead of cold ones. If it suppurates it is generally better to allow it to break. If sinuses form they must be laid open; and Mr. Hey recommends that, if any portion of breast is contained between two sinuses, it should be removed.

Scirrhus breast never happens under puberty, seldom under twenty-seven years of age, but mostly when menstruation begins to cease. It is sometimes situated at the nipple, sometimes it forms a substance superadded to the gland, but mostly attacks the latter, causing its structure to become altered. There is frequently in the first instance a bloody discharge from the nipple; then comes on a round tumor, hard knobbed and irregular, with lancing pain, but not always at the commencement; then the nipple is tucked in, the skin adheres and ulcerates, having every character of the cancerous ulcer as already described. After some time it becomes adherent to the pectoral muscle, and the affection spreads to the glands of the axilla or behind the clavicle.

Treatment.—This, like all other cancers, can only be cured by an operation, and this should not be performed if the neighbouring parts are much contaminated, or if the patient be old. The operation of removing this or most other cancerous tumors is a mere piece of dissection. The incision is generally double and semi-oval, to include the portion of diseased or superfluous skin, thus () ; the apex should point to the

axilla, so that if we find a gland diseased near the breast, we may extirpate it by this first incision; several small arteries are generally wounded, and may be compressed by an assistant. The dissection should now be continued on both sides, and then the base may be removed when we expose the pectoral muscle and meet with the mammary arteries. These are to be tied, and the ligatures left hanging out at the lower aperture. The wound is now to be closed by adhesive plaster, &c.

There are other diseases of the female breast not schirrus. One which grows to a very large size, the pancreatic sarcoma, which is not likely to return when removed, or there may be tumors containing hydatids, also to be removed.

SECT. VIII.—DISEASES OF THE ORGANS OF SENSE.

1. *Eye*.—Our limits will not admit of even a description of most of the disorders incident to this beautiful and complicated organ; we must therefore be content to describe one or two most interesting to the surgeon.

Fistula lachrymalis, which consists, in the first instance, of an obstruction of the lachrymal duct, so that the tears become accumulated in the sac, and after some little time flow over the face; then the tears lodging in the sac become inspissated, create irritation and inflammation of the sac, which however does not suppurate at first, but furnishes a thin mucus of a pale color, which, as the disease advances, gradually assumes a more purulent appearance; at last the skin over the sac, by repeated attacks of inflammation, becomes thin and bursts; and now the tears flow freely over the face, being extremely troublesome: the eye also becomes more or less inflamed, and the bones of the ductus ad nosum not unfrequently carious.

Treatment.—In the first stage it is best to inject some bland fluid, as milk or whey, into the nose from the punta lachrymalia, by means of Anel's syringe. Having thus cleared a passage for the tears, a slightly astringent and stimulating colyrium may be dropped into the eye, from which it will naturally find its way to the sac, and this is often successful; but, when the duct is quite closed, we may make an opening into the sac, or, if there be one already, dilate it; then pass a probe down the duct, and withdraw it, leaving in its place a silver style, with a small flat head, to prevent its slipping into the nose; this should be taken out and replaced once a day for about a week, and then less often: it may be discontinued in about a month or five weeks. But when the sacculus is quite obliterated, or the bones carious, a new passage altogether must be made; and for this purpose it is usual to perforate the os unguis which divides the posterior part of the sac from the cavity of the nose; this is effected by a small trephine, or a curved trocar, and into the aperture a style is to be introduced, as in the former case, for fear of the opening healing.

Extirpation of the eye may be required in cases of cancer, &c., and is to be performed thus:—The eyelids are to be divided at the outer canthus, to give freedom to the operation, and the conjunctiva to be separated above and

below; then the eye may be seized by a tenaculum, and a straight knife introduced above, and to the inner side of the ball, which thus divides the optic nerve and muscles at once. It may then be passed round under the eye to free it; a good deal of hæmorrhage generally occurs, but may be stopped by pressure: the inner surface granulates, and so heals.

2. *Nose*.—Polypus. There are two sorts which affect the nostrils, generally growing from the superior spongy bone; the more common one being transparent and gelatinous, and more liable to return; the other being fleshy, and not so liable. These occasion great uneasiness by plugging up the nostril, and sometimes deafness, by pressing on the opening of the eustachian tube; or one may even press on the jugular vein, causing giddiness, headache, and other signs of venous obstruction upon the brain. These are to be removed by an operation which consists in passing a curved pair of forceps as near the root as possible, and then pulling them away; but, as they depend upon a diseased state of the bone or membrane of the nose, they are liable to return; so that, when we have removed them, we should endeavour to cure or alleviate the disease by touching the part with some stimulating application, as the ung. hyd. nil. mitius.

Ozæna generally occurs in scrofulous people, but is met with occasionally in others. It begins with a sense of fulness in the nostrils, and discharge of mucus, as if the patient were affected by a common cold. This is caused by the membrane being thickened, which thus contracts the nostrils: this goes on increasing, till at last the patient cannot breathe at all through the nostrils, and he wakes in the morning with a dry tongue as hard as a board, giving him great uneasiness: this goes on for some time, till at last the membrane ulcerates, discharging a very fetid matter, and the bone dies and exfoliates. In the latter stage the patient feels pain in the nostrils, and at the root of the nose, on the forehead.

Treatment.—In the early stage we should employ stimulating and astringent lotions, or snuff; when the disease is more advanced, we may dip a camel's-hair pencil in the following liniment, and apply it all over the nostril internally: ung. hyd. nil. mitius: ol. olivæ, ā ā partes æqualis. Sometimes it is useful to give the oxymuriate of mercury and sarsaparilla. Ulcerated openings in the septum may often be cured by touching it with the ung. hyd. nil. mitius, or solution of argenti nitratum.

Abscess of the antrum highmorianum is occasioned by obstruction of the duct leading into the nose. It occasions the antrum to swell enormously, disfiguring the face; the bone grows as thin as paper, and there is very great pain. An opening must be made by drawing the third molar tooth, and perforating its socket into the cavity; or, what answers better, is to cut away with a curved knife a piece of the projecting tumor under the upper lip, where the bone is so thin that it may be cut easily.

3. *Mouth*.—Enlargement of the tonsils occurs often after common quinzy, especially in scro-

fulous persons. It alters the sound of the voice by obstructing the nose. It renders deglutition uncomfortable and obstructs the breathing, particularly during sleep, and sometimes causes deafness. This enlargement generally subsides spontaneously soon after the age of puberty.

Treatment.—If it is very troublesome we must endeavour to mitigate it by giving burnt sponge or iodine, steel bark or sarsaparilla, and send the person to the sea side. If this treatment does not succeed we may remove the whole or greater portion by ligature, or what answers better, as it is less inconvenient, is to cut off about three-fourths of it with a curved pair of knife-edged scissors, having probe points. The bleeding is not considerable and the pain trifling.

Some persons are affected with an elongation of the uvula, which thus drops down into the fauces, causing a constant cough and irritation. In this case we may snip off a portion and gargle the throat with astringent substances.

The lip is peculiarly liable to cancer, especially the lower one; in which case we should remove it, and by bringing the edges together, and retaining them by hare lip pins, we shall get them to heal without much deformity.

4. *Hare lip.*—This is a malformation of children, there being a fissure or longitudinal division in one or both lips. It most commonly exists in the upper lip, and the fissure may be double with a little portion of lip between them. It commonly affects only the lip, but sometimes extends along the bony palate as far as the uvula.

This deformity may be remedied by an operation, which is merely paring off the opposite edges, by a knife or scissors, in a straight direction, and bringing them together; and in order to retain them in apposition it is usual to employ one or more silver pins, at one end of which is a moveable point. These are thrust through the opposite parts and the points withdrawn. Then silk is to be twisted round them to retain them.

This wound being a clean cut unites by the first intention, but it is not prudent to take out the pins too early; they should be left for about four or five days, then sticking plaster will be sufficient. When there are two fissures we should operate on one at a time. When the bone is deficient it obstructs the voice and swallowing; a piece of sponge or metal plate may be adapted to fit it and will remedy these inconveniences.

PART III.

VARIOUS SURGICAL OPERATIONS AND OBSERVATIONS.

SECT. I.—OF AMPUTATION.

Amputation, derived from *ab* and *puto* (the *b* becoming *m* by vocal assimilation), implies the pruning off or severing from the body a diseased limb; and thus, by removing the offending part, allowing the constitution, which has become affected by sympathy, liberty to recover its pristine health and soundness. Something terrible associates itself in the imagination of mankind with the idea of cutting off a portion of the human frame, so that the application of the knife was looked upon as the last resort; according to

Ovid, *‘incurabile vulnus ferro encindendum est,* who has at the same time very well expressed the motive which renders an operation of this kind necessary. But, till within the last two centuries, the art of securing a lappet of flesh to cover and prevent the protrusion of the truncated bone was unknown. In the year 1679 it was proposed by Jacob Young, an English surgeon, in a treatise which bore the title of *Currus Triumphalis est Terebintho* to preserve a flap of flesh and skin which might be folded over the bone, and, by coalescing, effectually prevent the inconveniences of excoriation or rawness which might otherwise be apt to take place. We might antecedently conjecture that the first attempts were unsuccessful, owing to our ignorance of a method of healing the wound by the first intention, to an inaptitude of the instruments, and to an awkward manipulation in the operator.

Amputation may be rendered necessary either when a member is so much diseased as to be useless, or when it puts life in danger. The general causes rendering this operation necessary are bad compound fractures; extensive lacerated and contused wounds; part of the limb being carried off by a cannon ball or otherwise; the bones being unequally broken and not properly covered; extensive mortification; white swellings of the joints; large exostoses; ulcers attended with extensive caries; cancer or other incurable ulcers; varicose kinds of tumors; particularly distortions of the bones.

Amputation may also be sometimes necessary from violent hæmorrhages of some principal artery during the cure of a fractured limb, or from such a profuse discharge of matter taking place that the strength of the patient is exhausted. Lacerated and contused wounds may require amputation on account of hæmorrhage ensuing which cannot be stopped. Extensive mortification may take place, and such large quantities of matter be formed that the patient will be unable to bear up under the discharge. Where part of the limb is carried off it is necessary to amputate higher up, so as to cut the bone, as well as the soft parts, in such a manner as may admit of a much speedier and safer cure. When mortification occurs every thing ought to be done for the support of the patient till this symptom be stopped; the first sign of which is the appearance of an inflamed circle between the diseased and sound parts. As soon as the diseased begin to separate from the sound parts, amputation of the limb ought to be performed, and no time ought now to be lost, lest the patient suffer from the absorption of putrescent matter.

No part of surgery is brought to greater perfection than the manner of performing amputation. Before the invention of the tourniquet, and the method of securing the vessels by ligature, the operation was seldom undertaken; and a great proportion of those upon whom it was performed died soon after. In the present improved method one death does not happen in twenty, or even thirty cases. In performing the operation particular attention is to be paid to the spot where the incision is to be made; the quantity of skin and cellular substance necessary to be saved, so as to cover the muscles and ligæ

completely without being stretched; cutting the muscles in such a manner that they may unite with each other and entirely cover the end of the bone; the prevention of hæmorrhages during the operation; the tying of the arteries alone, without including the nerves or any of the contiguous parts; securing the integuments so as to prevent them from retracting after the operation; and a proper subsequent treatment of the case.

The following are the general steps of the operation:—The patient being properly placed, with assistants to attend, and the apparatus in proper order, the flow of the blood to the limb is to be stopped by the tourniquet. The first incision is to be made through the skin and cellular substance by one or two circular strokes of the amputating knife. These are next to be separated from the muscles as far as may appear sufficient for covering the stump. The separated skin or flap should be strongly drawn up, or, what perhaps answers better, turned up all round the limb, leaving this part of the muscles quite bare. The flap is to be kept in this situation by an assistant, while the operator makes the next incision at the edge of the reflected skin, and cuts till he comes to the bone. This incision should be begun on the lower side of the limb, that the blood may not prevent the eye from readily following the edge of the knife during the whole cut. The muscles are now to be separated from the bone as high as may enable them afterwards completely to cover it. The soft parts in general are then to be drawn up by retractors, which may be either of leather or metal. The periosteum is to be divided at the place where the saw is to be applied; but no part of the bone is to be denuded of this membrane, which is afterwards to cover the stump, otherwise troublesome exfoliations may ensue. At this place the saw is to be applied, and the bone divided with long steady strokes. In this part of the operation a good deal depends upon the steadiness of the assistant who holds the limb; for, if it be held too high, the motion of the saw will be impeded; while the bone may be splintered if it be not sufficiently raised. Any points or splinters which may be left should be immediately removed with the pincers. The retractors are now to be laid aside, and the principal arteries separated from the nerves, and secured by the tenaculum, or forceps, and ligatures.

The tourniquet should next be a little slackened, to allow the different branches to be discovered. The clotted blood is to be cleared away with a warm sponge. The patient should get some warm cordial drink, and all the arterial branches which can be discovered ought to be taken up. The ends of the ligatures are then to be cut of such a length as to allow them to hang without the lips of the wound. The muscles and skin are now to be drawn down and brought into close contact, that the stump may be completely covered. The parts are next to be secured by proper bandaging; and, if the operation has been properly performed, the cure will commonly be made by the first intention, and may be completed in the course of three or four weeks, and sometimes in a shorter period. This, however, must depend much upon the constitution

of the patient, as well as the manner of performing the operation.

Of amputation of the arm and fore-arm.—Amputation of the arm is performed according to the rules already laid down. No more of it should be removed than is diseased; for the longer the stump is the more useful it proves. The tourniquet is to be applied a little above the part where the operation is to be performed; as much of the integuments should be saved as may be perfectly sufficient for covering the sore. In taking up the artery, after the bone has been divided, the operator ought to be attentive not to include the radial nerve, which may be readily discovered and separated, as it lies close upon the fore part of the artery. The fore-arm is to be amputated nearly in the same manner as the leg; only that the stump may be covered by amputating with the double incision, without the assistance of a flap, which it is necessary to form in the leg.

Of amputation of the thigh.—In performing this operation the patient ought to be placed upon a table of ordinary height, with the diseased limb supported and secured by an assistant seated before him, while other assistants take care of the other leg and the arms. The course of the blood is to be stopped by applying the tourniquet over the trunk of the femoral artery, near the upper part of the thigh. No more of the thigh ought to be removed than is rendered necessary by the disease, as the more of it is left the more useful it will be to the patient. An assistant, should grasp the limb with both hands a little above the place where the skin is to be divided, and draw it up as far as possible; while the operator, standing on the outside of the limb, makes a circular incision down to the muscles by one or two strokes of the knife. As much of the integuments is then to be dissected with a scalpel from the muscles as may cover the stump completely; and this part of the skin may either be turned back or drawn tightly up by an assistant. The muscles may then be divided quite across to the bone by the edge of the skin, in the common way, or cut obliquely upwards, according to the method of Allanson, so as to lay the bone bare two or three fingers' breadth higher than is done in the common way. The muscles are next to be separated from the bone with a scalpel a little way, that a sufficient quantity may be left for covering the end of it. The rest of the operation is to be performed exactly according to the general rules laid down in sect. I. The muscles and integuments are to be drawn over the end of the bone, and applied closely together, that the skin may completely cover the stump, and retained in this situation by an assistant till a flannel or cotton roller, according to the season of the year, which has been previously fixed round the body, be applied in such a manner as to support and fix them. For which purpose it should be passed two or three times, in a circular direction, round the top of the thigh, and should afterwards, with spiral turns, be brought down near to the end of the stump, and fastened with pins; and it should not be tighter than may be sufficient to assist the plasters in preventing retraction.

The ends of the divided muscles are now to be laid exactly over the bone; and the edges of the skin are to be brought into contact, either so as to form a straight longitudinal line, according to the method of Mr. B. Bell, &c.; or they are to be placed horizontally, 'that the wound may appear only in a line with the angles at each side,' as advised by Allanson. The ligatures may either hang over the edges of the wound, or be brought to the angles. After the edges of the skin are in this manner exactly applied to each other, either a few slips of adhesive plaster are to be laid across the face of the stump, or two large pieces of adhesive plaster, with several pieces of tape fixed to them, are to be applied to the surface of the skin. The tapes are then to be tied with a running knot immediately over the wound; by which the parts will be kept so closely together as to prevent any collection of matter from being formed. The whole surface of the stump should next be covered with a large pledget spread with an emollient ointment, over which a compress of fine tow is to be put, and retained in its place by a broad cross strap of old linen, passing some way up the thigh, so as to be secured by the roller, which is now to be passed two or three times round the stump; and the pressure formed by the cross strap may afterwards be increased or diminished at pleasure, by drawing it with more or less tightness, and fixing it with pins to the roller. While the stump is dressing the tourniquet is removed, but replaced again loosely to enable the attendants to check any hæmorrhage which may afterwards ensue.

The patient is now to be laid to rest, and the limb is to be placed upon a little tow covered with linen, or upon a thin soft pillow; and to prevent the patient from involuntarily moving the limb, and to guard against spasmodic startings, which frequently happen after this operation, it may be fixed to the bed by two straps. A basket or hooped frame ought to be placed over the stump to protect it from the bed-clothes. The patient should immediately get an anodyne draught, which will generally procure ease through the rest of the day. For this purpose no more light should be let into the room than is merely necessary for allowing the attendants to pay attention to the stump. As hæmorrhages sometimes appear several hours after the operation, the person who takes the charge of the patient should watch this circumstance with the greatest attention. If there be only a slight oozing of blood there is no occasion for being alarmed; but whenever it appears to proceed from a large artery it must be secured. The spasmodic affections which frequently occur after amputation are seldom troublesome, unless some nerve has been included in securing the arteries; but, when they do appear, laying the limb in the easiest posture, and giving opiates, are the principal means of procuring relief.

To prevent inflammation as much as possible, the patient is to be kept upon a strict antiphlogistic regimen, and his bowels kept open by laxative clysters till the inflammatory stage is over, which will generally be in a few days. If, notwithstanding this treatment, the stump swells,

and the patient complain of pain and tightness, we ought to endeavour to discover from what cause the uneasiness originates. If it be owing to the straps being too tightly fixed they must be slackened. If the stump be found much swelled, a saturnine solution should be applied by means of several folds of linen; and if the patient be young and plethoric he ought to lose a few ounces of blood from the arm; but if he is weak and emaciated a different mode of treatment must be followed.

At the end of the third or fourth day, at farthest, the stump should be examined; and if it appear somewhat open and flaccid, the parts must be brought closer together and secured more firmly. After this time the dressings should be renewed every day, or every second day. In about a week after the operation the ligatures may generally be removed with ease; but if they do not separate readily they may be gently pulled at every dressing, when they will, in a short time, be brought away, and the wound will be soon healed by the first intention. The roller should be cleaned and renewed as often as it is found sullied; nor should it be laid entirely aside till the end of the third or fourth week after the operation. When the roller is removed, we may depend upon the straps or tapes for keeping the parts together till the cure be quite accomplished. When the inflammatory symptoms are entirely gone, no medicines ought to be given which would debilitate the patient, nor is any thing more necessary than to keep the bowels gently open till a complete cure be made.

Of amputation of the leg.—The leg may be amputated for a disease in the foot at two different parts; the one a hand-breadth under the knee, the other a little above the ankle. The former makes a sufficient support for the body to rest upon an artificial leg, but the latter does that equally well, and likewise preserves the motions of the knee.

In performing the operation a little way under the knee, the patient is to be placed and secured in the same manner as in operating upon the thigh. The tourniquet is to be placed a little above the knee, with the cushion upon the artery in the ham. The surgeon places himself upon the inside of the leg, and makes a circular incision through the integuments down to the muscles. The place where the incision should be made must depend upon the length of the limb; but in general it may be between six and seven inches under the top of the tibia in an adult, or far enough down upon the limb to save as much integuments as will cover the stump. After the integuments are cut through, in the manner already directed, as much of the muscles are to be divided by the knife as can be done by a circular incision; and the interosseous parts are to be divided by a scalpel or catlin. The retractors are then to be applied, and the bone sawed off immediately below the insertion of the tendons of the flexor muscles. In sawing, the operator ought to begin upon both bones at the same time, that he may finish upon the tibia, lest splinters should be formed. The vessels are next to be secured; the soft parts drawn over the bones; the adhesive plasters and other bandages

applied in the same manner as directed for amputating the thigh, only that here the roller need not be applied so high as in the former operation. Two or three turns above the knee, however, are necessary to prevent the dressings from slipping down.

In amputating upon the ankle, the operator should fix upon that spot which will leave the stump of such a length as may be most convenient for being fitted with an artificial machine resembling the other leg. Nine inches from the joint of the knee, in a leg of ordinary length, was found by Mr. Wilson, a late ingenious artificial limb maker in Edinburgh, to be the best part suited to this purpose, on account of the equal pressure it makes upon the surface of the leg, without making any upon the end of the tender stump. The operation is performed in the same manner as that a little below the knee.

Of amputation at the joints of the extremities.

—The circumstances most to be attended to in performing amputation at the joints are, first to stop the circulation by the tourniquet; or, where that is impracticable, to take up the trunk of the artery by a ligature; to make a circular incision in such a place as may, after the operation is over, be sufficient to cover the wound; then a longitudinal incision is to be made upon the opposite sides of the limb, extending from the joint to the circular cut, and as deep as the bone, by which two flaps will be formed to cover that part of the joint which remains after the operation is finished. The ligaments of the joint are next to be divided, and the affected limb or part of the limb removed. After this part of the operation, it was formerly a frequent practice to scrape off the remaining cartilage, to unite the parts more firmly together. But this is now found to be unnecessary; for, when the flesh is applied properly to the bone, if it do not grow to it, the union at least is so close that it afterwards gives no inconvenience to the patient. Any branches of arteries which may have been cut during the operation are now to be secured; clotted blood is to be removed; and the muscles and skin are to be brought into close contact with the ends of the ligatures hanging out of the wound. The parts are to be retained by adhesive plasters, or twisted suture, or both; and proper bandages applied in such a way that a cure may be made by the first intention.

Amputating the arm at the shoulder joint has always been considered as a dangerous as well as a difficult operation. It should never be attempted, when the same purpose can be accomplished by operating lower down. But cases occasionally occur where the life of the patient cannot, in any other manner, be saved.

Amputation may become necessary here in consequence of abscesses of the joint; caries of the humerus reaching to the joint; compound fractures, especially those from gun-shot wounds, extending to the head of the bone; and of mortification.

In performing the operation, the patient should be laid upon a table of convenient height, covered with a mattress. He is then to be brought as near to the edge of it as possible, and secured by assistants. The circulation of the blood in the arm is next to be stopped, by

an assistant pressing strongly with a firm compress over the subclavian artery, where it passes over the first rib; or an incision may be made along the course of the artery, which may be secured after separating from it the contiguous nerves. When the artery is compressed, it will readily be known whether the compression proves effectual, by observing when the pulse at the wrist is entirely stopped. As soon as this is the case, a circular incision is to be made through the integuments at the insertion of the deltoid muscle into the humerus. An assistant then draws the skin a little back, and at the edge of the retracted skin the muscles are to be cut in a circular direction to the bone. If the artery has not been taken up at the beginning of the operation, it is now to be secured, as well as any branches which come in the way.

The amputation knife is now to be laid aside, and the rest of the operation finished with a strong scalpel. A perpendicular incision is next to be made at a little distance from the outside of the artery, beginning at the acromion, and terminating in the circular incision, cutting as deep as the surface of the bone. A similar incision is to be made upon the back part of the arm, so that the flaps may be nearly of an equal breadth. The arterial branches are here to be secured; the flaps are to be separated from the bone, guarding against wounding the trunk of the artery; the flaps are to be supported by an assistant; and the capsular ligament of the joint is to be cut from the scapula: and thus the arm will be entirely separated.

After the arm has been separated, any arteries which appear about the joint are to be tied, and all the ligatures brought over the edges of the wound. The parts are to be cleared of clotted blood, and the two flaps drawn over the wound, and secured by the twisted suture. A pledget of any emollient should then be applied, and a sufficient cushion of lint, with a compress of old linen, put over the whole. A moderate pressure is next to be applied by a flannel roller; by which the parts will be supported, their union facilitated, and matter most likely prevented from being lodged. The treatment is then the same with that after amputation in other parts of the extremities. For two or three days after the operation, it is necessary that an assistant sit with the patient to compress the artery in case a bleeding should ensue.

When it is necessary to amputate the whole hand, the operation may be performed at the wrist, so as to leave as much of the member as possible; and the same rules hold here as in amputating at any of the rest of the joints. The tourniquet is to be applied to the artery in the arm, and the cure is to be completed by the first intention. When any of the carpal bones are affected, the sore will not heal till they either work out by suppuration, or are cut out by the knife. When the middle of any of the metacarpal bones is diseased, while their extremities are sound, the trepan may be applied, and the diseased parts removed, while the remaining sound parts are preserved. But if the whole bodies of one or two of these bones be affected, while the rest remain sound, all the affected bones ought to be removed. In performing the

operation, an incision is to be made along the course of the part affected; and, if the operator have it in his choice, the incision should be made upon the back part, so as to save the great vessels and nerves situated in the palm. The integuments are then to be dissected, and turned to each side; after which the diseased bones or parts of bones are to be removed, guarding as much as possible against wounding the principal arteries or nerves which lie near them.

The diseased parts are next to be separated; any arteries which happen to be cut are to be secured; and, on account of the free communication which they have with neighbouring branches, they ought to be tied at both cut ends. If, after this, a bleeding still continue, compresses, styptics, and other remedies proper for stopping blood, are immediately to be used. The sides of the wound are to be brought together, and an attempt made to cure them by the first intention.

In amputating the fingers, it was formerly the practice to operate upon the bodies of the bones in the same manner as in the larger extremities; but at present the removal at the joints is more frequently practised. In performing the operation, it is necessary to save as much skin as may cover the stump, and this ought to be done upon the side next the palm, so as to guard against the effects of friction. The general steps of the operation are the same with those for amputation of the larger joints.

A circular incision is to be made on the finger by a crooked bistoury, about the middle of the phalanx, and it may be carried at once to the bone. Another incision is to be made with a common scalpel at each side of the finger, beginning at the circular one, and continuing it to the joint, by which two flaps will be left to cover the stump. The ligaments of the joints are now to be divided, and the bone removed. The blood vessels are to be secured by ligature, and the flaps exactly applied to each other; but, in order to protect the end of the bone completely, a small portion may be cut from the uppermost flap. The flaps are to be retained by adhesive plaster, or by the twisted suture; but if the latter be used, the tendons ought to be avoided. Over the sore an emollient pledget is to be applied, and then a compress and roller. If the disease be so situated that, instead of amputating at the cavity of the joint, the surgeon shall think proper to operate upon the body of the bone, flaps are to be formed as above, and the bone is to be divided by means of a small spring saw.

The amputation of the thigh, at the hip-joint, has always been considered as one of the most formidable operations in surgery; so much so, that very few cases appear on record of its having ever been put in practice. In the Medical Commentaries of Edinburgh an instance is recorded where the thigh was amputated at this joint, and where the patient survived the operation eighteen days, and then died from a different cause, when all risk of hæmorrhage was over, and when the sore had even a favorable appearance, which shows at least that the operation has been done with safety. It certainly ought never to be done, however, unless as the last resource,

and when the life of the patient is in absolute danger; and then only when as much skin and muscles can be saved as will cover the sore, and when there is also a probability of being able to stop the hæmorrhage, and prevent it from returning.

When the operation is to be performed, the patient is to be laid upon his back on a table, and properly secured by assistants; one of whom should be ready with a firm cushion to press, if necessary, upon the top of the femoral artery, just after it passes from behind Poupart's ligament to the thigh. A longitudinal incision is now to be made through the skin, beginning immediately under the ligament, and continuing it downwards along the course of the artery for about six or seven inches. The aponeurosis of the thigh is then to be divided by gentle scratches till a furrowed probe can be introduced, when the opening is to be dilated by means of a scalpel, till two or three inches of the artery be laid bare. A strong ligature is now to be put under the artery by the assistance of a curved blunt-pointed needle.

The part where the ligature should be passed is immediately above the origin of the *arteria profunda*; for, if that artery be not affected by the ligature, the patient might suffer by the loss of blood during the rest of the operation. The ligature is now to be secured by a running knot; another ligature is to be introduced a little below the former, and likewise secured; the artery is then to be divided between the ligatures. A circular incision is now to be made through the integuments of the thigh, about six inches from its upper end. The retracted skin is then to be pulled at least an inch upwards, and at the edges of it the amputating knife is to be applied, so as to cut the muscles down to the bone. This being done, a cut is to be made upon the posterior part of the thigh, beginning a little higher than the great trochanter, and continuing it down to the circular incision, and as deep as the joint. A similar cut is to be made on the anterior part of the thigh, at a small distance from the artery, and this reaching likewise down to the bone. The two muscular flaps are to be separated from the bone and joint, and held back by an assistant. Every artery which appears is now to be secured. Then the capsular ligament, and next the round one, are to be separated from the acetabulum; by which means the limb will be removed from the body. The acetabulum and neighbouring bone are next to be examined; and, if they appear sound, the case will be more favorable; but, at any rate, a cure is to be attempted by the first intention. For which purpose, after removing all the clotted blood from the surface of the wound, and bringing the ligatures over the edges of the skin, the muscles are to be placed as nearly as possible in their natural situation; and, drawing the flaps together so as to cover the wound in the most accurate manner, they are to be kept in this situation by adhesive plaster, and by the twisted suture and other dressings, as in amputating at the under part of the thigh. The dressings are to be retained by a broad flannel roller passed three or four times round the body, and spirally over the stump, and se-

cured. The patient is then to be laid in bed on the sound side, and treated as for amputation in other parts of the body; only that greater attention is necessary, as there is no assistance from a tourniquet. Uncommon attention will also be necessary to prevent inflammation, and every symptom of fever which may succeed to the operation.

When the foot is so much diseased as to require amputation, the operation might be performed at the point of the ankle; but, for the reasons given when treating of amputation of the leg, it is found better to do it above the ankle. When a considerable part remains sound, it ought to be saved. If any of the tarsal bones are affected, these are to be removed. When the middle or whole body of any of the metatarsal bones are diseased, they are to be removed in the same manner as directed for similar operations in bones of the hand; and, if even two of them remain sound, provided they be so placed as to support the toes, they ought to be preserved, as it is known that, by proper treatment, an osseous matter may afterwards fill a considerable part, if not the whole, of the void; or, if any cavity remain, it may be so stuffed that the use of the foot may still be enjoyed.

In performing an operation of this kind, the patient should be laid upon a table, and the tourniquet applied in the ham to prevent hæmorrhage. An incision is then to be made along the affected part; and, if the seat of the disease admit it, the incision should be made upon the upper side of the foot, so as to save the sole. The integuments are to be separated and turned to each side, to allow the affected parts to be completely removed. The principal vessels and nerves are to be saved as much as possible; but, if any particular artery be cut, it is to be secured, and the part treated as after the removal of similar parts of the hand. The amputation of the toes is exactly similar to that of the fingers.

Of removal of the ends of carious bones in the joints.—In compound fractures, the ends of bones, when they protruded in such a manner that they could not otherwise be returned, have frequently been sawed through, and their place has frequently been supplied by a renewal of bone, so as to preserve the ordinary use of the limb. Many cases have likewise happened where a large part of the body of the bone has been thrown out by suppuration, and its place supplied; and a few are upon record where either the whole of a bone, or that end next the joint, has been thrown out, and its place filled up with callus, so that no inconvenience has been felt. From these circumstances, Mr. White of Manchester was led to preserve an arm by sawing off the head of a diseased humerus; and Mr. Park of Liverpool to save a limb, by sawing off the ends of the bones, in a case of white-swelling of the knee. When therefore it happens that the end of a bone is diseased, while the other parts are sound, the diseased part may be removed, and the sound one saved, so as, in a great measure, to preserve the free use of the limb.

In performing the operation, the first step should be to use such means as may enable the operator to have a full management of the circu-

lation of the part affected. Then a longitudinal incision of sufficient length, and perhaps another across it, may be necessary to be made through the soft parts of the joint; and this opening ought to be at a distance from the large blood-vessels, that they may be in no danger of being injured. After the end of the diseased bone is sufficiently laid bare, it is either to be brought out of the joint, or a spatula or some other proper substance is to be introduced between the bone and soft parts, so as to defend the latter in time of sawing the bone. After the diseased part of the bone is removed, the arterial branches are to be secured, and the wound treated like any other wound of equal size.

During the cure, the limb ought to be kept in the posture most favorable for the removal of the bone, and afterwards for the preservation of the natural motion of the joint. In this way a limb may sometimes be saved which would otherwise have been removed. But, though the removal of the diseased end of one bone may be readily effected, the removal of all that part of the bones which enters into the composition of a joint must be attended with so much inconvenience that it can seldom be useful, unless it be where the ends of bones are destroyed by external violence; for then it appears that this operation may be performed with considerable success.

SECT. II.—OF OPHTHALMIA, AND ITS TREATMENT.

Ophthalmia is generally understood to mean the inflammation of the eye, but since this term is derived from *οφθαλμος*, the eye, without any adjunctive to specify on what account the eye is alluded to, there is nothing prescriptive in the sense, and we may extend its signification so as to make it embrace all those diseases which have their origin and seat in parts of the eye. The disease of which we are about to treat may be induced by a variety of those causes which operate in producing inflammation in other situations; a severe cold in the eyes, if it should be contemporaneous with some affection in the pituitary sinuses, fauces, and trachea, will occasion the disease in question. Other exciting causes have been enumerated, such as a change of weather, sudden transition from heat to cold, the prevalence of cold winds; residence in damp or in sandy countries, during the seasons of summer's drought, exposure of the eyes to the glaring light of the sun, &c. Since from the nature of things a multitude of similar causes are likely to happen at the same time, it ought not to seem extraordinary that the ophthalmia should sometimes put on the appearance of an epidemic and afflict persons of every age and sex. Mr. Green has presented us in Castle's Manual with such an excellent arrangement and description on the indications and treatment of the various modifications of diseases affecting the different parts of the eye, that we cannot do better than avail ourselves of a portion of such valuable materials, beginning with the simple inflammation of the conjunctiva.

1. *Simple inflammation of the conjunctiva.*—Simple inflammation of the conjunctiva may be divided, like other inflammations, into acute and chronic; and first of the acute.

(1.) *Acute ophthalmia.*—The symptoms of the affection in question do not differ from those of chronic inflammation of other parts of the body, except in so far as they are modified by the structure of the part, and by the function of the organ. We will speak of the local appearances, and afterwards of the constitutional derangements.

The first symptom is redness of the part, which is very remarkable, because the blood naturally conveyed by the vessels to this part is colorless. The vessels become injected with red blood. When the irritation continues the vessels become still more apparent, and at length all the interlacements and anastomoses of the vessels of the conjunctiva partake of the inflammation, and present almost one uniform appearance of redness. During this time more or less pain is experienced; at first, as the vessels become filled, an uneasy sensation is felt; this increases, and at length, upon the admission of light, a sharp lancinating pain is experienced; the patient is under the necessity of keeping the eye closed, and, indeed, has some difficulty in raising it not only from the pain he suffers, but from the degree of fulness and swelling with which it is accompanied. This pain goes on increasing, and at length the patient complains of a burning heat and a sensation as if some extraneous body were lodged in the conjunctiva of the lid. At this time the admission of the least light or air produces such lancinating pain that the eye is spasmodically closed. The affection is also attended with a more abundant secretion of tears, which, at the highest stage of excitement, is suddenly diminished, and there is a preternatural dryness of the eyes, producing painful sensations. A considerable degree of swelling takes place, the conjunctiva becomes turgid from the quantity of blood admitted by the vessels, and effusion follows. Although the swelling is pretty equally diffused over the whole surface of the conjunctiva, it seems to be the greatest at the transparent cornea, because here the coat is more tightly adherent. The conjunctiva is here elevated in a circular fold, and this appearance is called chemosis. The eye-lids are in general more or less swollen. Not only is pain experienced in the eye, from the causes I have mentioned, but also a sense of weight and fulness in the globe of the eye, as if the ball were too large for the socket. The neighbouring parts also, the forehead and temples, partake of the pain; there will be a shooting pain to the maxillary bone, or more deeply seated in the head; and these pains are in some instances extremely violent.

The local symptoms, as we have already hinted, are attended with considerable constitutional effects. There will be a greater or less degree of constitutional irritation; great lassitude; prostration of strength; chilliness or rigor followed by heats. The skin will often be hot and dry, pulse quick and hard, stomach affected, and vomiting produced. The patient will also complain of pain in the back, and in short, of all the symptoms which indicate a considerable fever of the sympathetic kind, arising from local irritation. The degree in which the symptoms of this disease occur, will very much depend on the constitution of the patient.

(2.) *Chronic ophthalmia.*—The term chronic, to inflammation of the conjunctiva, is not applied merely with reference to duration of time; it is not only applied to signify that state of congestion and debility of vascular action produced by the acute stage; but it is also applied to that state of inflammation which from the commencement has a character of atony and debility. As this is the most frequent form in which you will find this inflammation, whether primary or following the acute stage, it is necessary to attend particularly to the symptoms by which it is distinguished, as the mode of treatment is very different from that which is required in acute inflammation. The symptoms of chronic differ from those of acute inflammation of the conjunctiva rather in degree than in kind; so that after they have existed for some time in the acute stage, you find the disease gradually passing into the chronic stage. The redness will be less intense, the pain which accompanies it less acute, the intolerance of light will be less, the chemosis and swelling will be diminished, the effusion of tears less considerable, the constitutional irritation will in a great degree have subsided, and, in short, all the acute symptoms will be mitigated. There will still, however, remain a considerable degree of irritability in the eye, on exposure to light; some artificial defence to exclude the light will be necessary, and the person will still be incapable of applying the organ to the ordinary purposes of vision. The causes of chronic inflammation, both exciting and predisposing, are very similar to those of acute inflammation; but there are many causes which tend to produce this inflammation, accompanied with atony and debility in the very onset, which distinguish it from acute inflammation. Chronic inflammation of the conjunctiva is very apt to take place, where the patient has for a long time been laboring under disorder of the digestive organs. It is not unfrequently the concomitant of dentition, the measles, or small pox; it sometimes accompanies rheumatism and gout. Frequent intoxication and various other causes may predispose to it. It is also very apt to arise from, or to be kept up by exposure to acrid fumes or smoke in particular trades. In general, inflammation of the conjunctiva is a very manageable complaint. It passes into chronic inflammation after the acute stage has continued for a certain time, and it not unfrequently subsides of itself. A spontaneous cure must not, however, be depended on, and we ought on no account to neglect or relax in the proper mode of treatment, from any reliance upon such a cure; because by simple inflammation of the deeper seated tunics of the globe of the eye, suppuration may be induced, the organ may at length become permanently disorganised, and the sight of the eye irretrievably lost. The consequences of inflammation of this membrane are very similar to those of inflammation in other parts of the body; namely, effusion, adhesion, suppuration, ulceration, and mortification. It sometimes terminates in effusion, the serum or blood under the conjunctiva rising in a roll above the cornea. It sometimes produces the adhesive process; and, when it terminates in this manner, the adhesive matter is deposited

under the conjunctiva, which covers the transparent cornea, and is recognised by a hazy appearance at the part. The adhesion is various, both in extent and quantity; it is sometimes so slight as only to produce a simple clouded appearance over a certain part of the cornea, which is technically called nebula; it is at other times more considerable in quantity, and produces an appearance of considerable opacity in the cornea, which is usually called albugo or leucoma. The inflammation sometimes proceeds to the suppurative process; indeed, the tunica conjunctiva appears to be of a nature very analogous to the mucous membranes of the body, and, like these, is exceedingly prone to the suppurative stage of inflammation. The suppuration generally proceeds from the surface of the conjunctiva, as from the surface of any mucous membrane in a state of inflammation. In other instances, the formation of pus is circumscribed; a deposit of lymph takes place where the conjunctiva covers the cornea, or in its immediate vicinity, and a little abscess or pustule arises from the centre. Ulceration is sometimes produced, and this usually occurs in the cornea in consequence of laying open the pustule just alluded to, probably from the denudation or exposure of the cornea. Lastly, sloughing and mortification of the cornea is not an uncommon effect of a high degree of suppurative inflammation.

Treatment.—In the treatment of simple inflammation of the conjunctiva it will be necessary to adopt at once, with vigor, antiphlogistic remedies, as the best mode of diminishing the action of the heart and arteries; and with this view the use of the lancet should be freely resorted to in the commencement. You ought not to be satisfied with taking away a certain quantity of blood; as, for instance, eight, ten, or sixteen ounces; but you should in this, as in all other cases of acute inflammation, accompanied with hardness of the pulse, make a free orifice in a large vein, and take away a quantity of blood, until some manifest effect is produced upon the action of the heart and arteries; keep your finger on the pulse of the patient, in order to ascertain how the heart is affected, and carry on the bleeding even to faintness. This may prevent the necessity of again having recourse to the lancet; or, if it should be necessary to do so, blood may be taken away in much smaller quantities. You will of course be guided by the state of the patient's pulse, as the only criterion.

When you have diminished the pulse, by general bleeding, leeches may be afterwards conveniently applied, and other resources made beneficial. The application of leeches in the first instance, except in very large numbers, is seldom sufficient in acute inflammation; three or four will scarcely produce any effect upon it. Opening the temporal artery has been recommended, and it is attended with very good effect. Some practitioners advise the practise of dividing the vessels of the part by scarifying the conjunctiva, but it is a plan we do not recommend.

Great benefit is derived from treatment directed more especially to the body at large; such as diaphoretic medicines; and the constitutional irritation may be materially abated by keeping

up the secretions from the intestines, by altering them and rendering them more healthy.

The tartarised antimony should be used with the first view. The bowels should be freely acted upon by doses of calomel, combined with jalap, scammony, or cathartic extract; and the effects of these medicines should be kept up by the exhibition of neutral salts, so as to produce a considerable number of watery stools. At the same time the diet of the patient should be low, and he should be kept in a state of perfect rest and quietude. When an impression has been produced on the symptoms, by the treatment we have laid down, it will then be proper to adopt other measures.

For instance, where blood has been taken to a considerable extent, the application of a blister to the nape of the neck will be attended with beneficial effects. The treatment of the part should also be considered, the head should be raised, and the access of air or light should also be prevented, by keeping the room darkened. With respect to local applications, both warm and cold remedies may be used with benefit, but the choice should depend entirely on the feelings of the patient; if he does not find relief from warm, you should then try the effects of cold applications.

Such is the plan of treatment you would adopt in acute inflammation of the conjunctiva; but, when the chronic stage has commenced, you must pursue a different course. The evacuating plan may to a considerable extent be laid aside; the diet, though not stimulating, may be generous; there will be no necessity for continuing the diaphoretic medicines, as the skin will generally be sufficiently moist; nor will it be necessary to evacuate the bowels so freely, though every attention should be paid to their due action; alterative medicines will often be found beneficial.

The local applications which are used for the chronic inflammation should be entirely different from those used in the acute. They ought to be moderately astringent and stimulating, as your object now is to excite some degree of action in the vessels, and to get rid of their relaxation and atony, care being taken not to stimulate the parts too much. Various collyria or eye-waters are used for this purpose, all of them moderately astringent or stimulating; such as the solution of alum in water, solutions of the sulphate of zinc or the sulphate of copper, or the liquor plumbi subacetatis. These solutions at first should be very much diluted, and afterwards gradually strengthened in proportion to their action on the part, and the degree of stimulus which may be produced. To judge how far the stimulus may be carried, the criterion is exceedingly simple; if you find that a certain degree of smarting and pain is produced, which soon subsides, and leaves the patient much more easy than before, you may be convinced that the collyrium is beneficial; if, on the other hand, the patient experiences a great degree of pain, which does not subside speedily, and the vessels become turgid, you may be assured that the collyrium is doing harm, and that the quantity of stimulus ought to be diminished. Among the numerous applications recommended in this

complaint, we will speak of those most frequently employed, and the manner of using them. Those commonly employed are the solution of alum in water, solutions of the sulphate of zinc, or the sulphate of copper, or the liquor plumbi subacetatis; and the best mode of applying these eye-washes is to inject them by means of a silver or ivory syringe, introduced under the lids every three or four hours. In this way, you may be certain that the solution is diffused over the whole surface of the conjunctiva. An eye-cup will answer the purpose very well, if the person, after immersing his eye in the cup, has the courage to open it. They will succeed better with the chill off than otherwise. The *vinum opii* seems to be one of the best stimuli which can be employed in chronic ophthalmia; it acts as a mild astringent, and at the same time, by its soothing quality, sheaths the effect of the stimulus, so that no pain is produced; it may be employed in the quantity of one drop, or even of two or three drops, two, three, or four times a day. *It will be best to drop it into the inner canthus of the eye, with a camel-hair pencil; the patient should then shut his eye, and move it about, so that the fluid may be diffused over the whole surface. The patient should wear no bandages, have no other protection than a shade, and, if he can bear a moderate degree of light; it should be freely admitted.

In addition to the local treatment we have gone through, you must give those medicines which will act on the morbid state of the constitution.

Of purulent ophthalmia.—Suppurative inflammation of the conjunctiva is the most severe form of inflammation in that membrane. It is exceedingly acute, very rapid in its progress, and often very destructive in its ultimate effects; consequently requires very active treatment.

The symptoms of purulent ophthalmia are so manifest that there can be no doubt of the nature of the complaint, its prominent character being the formation of a considerable quantity of purulent matter. In other respects the symptoms are not very different from those which characterize inflammation generally. The patient at first feels an uneasy sensation about the eyes; next some degree of pain on the admission of light; redness, and swelling of the part; eyelids swollen; conjunctiva, where it covers the fore part of the globe of the eye, is tumid; considerable chemosis, and often such tergescence of the upper lid as to prevent the patient from raising it. The lids are often so much tumefied as to become everted, so that a sort of roll of the lid is formed. These are the symptoms which precede the discharge of matter. A fluid first appears which is not opaque, and has the character of tenacious mucus; in the course of twenty-four hours it assumes the appearance of pus. It is thick, yellow, sometimes green, and poured out in considerable quantity. The tunica conjunctiva has the appearance of a villous membrane highly injected.

The acute stage of purulent ophthalmia is of very short duration; it has a tendency to pass rapidly into the atonic stage, in which there is action without power, and congestion of the

vessels of the part. At this time the violence of the acute symptoms is mitigated, but the patient labors under considerable prostration of strength. Purulent ophthalmia has a great tendency also to terminate in sloughing. Sometimes the sloughing commences in a small portion, and gradually lamella after lamella is destroyed, until the aperture assumes a funnel-like shape; at other times a slough forms in a considerable portion of cornea at once, and opens into the anterior chamber.

The causes of purulent ophthalmia are various: it is often occasioned by the violent degree of inflammation produced by some highly irritating substance; and it occasionally occurs in newborn infants. In the last case it is doubtful whether it arises from the first exposure of the eye to the light, or, as is commonly supposed, from the vaginal secretions to the eyes of the child on its passage into the world. It generally takes place in the first week or month after the birth of the child, and seldom later than three months. Another, and one of the most violent forms of purulent ophthalmia, is that which is called gonorrhœal, from its being produced by the application of gonorrhœal matter to the conjunctiva. This of all others produces the most intense degree of inflammation; and, although it is said upon good authority to be depending on a metastasis of the gonorrhœal symptoms from the urethra to the conjunctiva, I have never seen a case in which I could entertain the least suspicion that the complaint was produced in that way, and I do not think that there is sufficient evidence to establish such an opinion.

There is another form of ophthalmia, which has been called the epidemic or Egyptian. Although we cannot correctly ascertain the cause of this affection, there can be no doubt that it arises spontaneously, and often attacks epidemically a number of persons in the same district.

Treatment.—The treatment of purulent ophthalmia must obviously very much depend on the stage of the complaint. During the first stage, when all the indications of acute inflammation are present, you must bleed largely from the arm of the patient; topical bleeding is out of the question except with children. All the other antiphlogistic remedies, which I before enumerated to you, are to be put in practice in this case. Purgatives should be administered so as to produce a considerable quantity of watery stools; diaphoretic medicines, and especially the tartarised antimony, in doses of a quarter to half a grain, should be given at such intervals as to keep the patient in a state of nausea; and topical applications should be employed very much in the same manner as in simple inflammation. During the first stage of the complaint, moist warmth in the form of fomentations and poultices, will be found beneficial: the acute stage, however, is of very short duration, and they are not to be continued beyond that period.

The extent to which the antiphlogistic plan should be carried, must vary according to the violence of the complaint and the constitution of the patient. You must not in any constitution be deterred from adopting an active plan of treatment until you have produced a manifest

effect on the system of the patient; until the pulse becomes soft; the skin moist; the pain, swelling, tension, and throbbing of the eyes considerably abated; the chemosis diminished; and, in fact, all the acute symptoms more or less subdued. When this is the case, the subsequent treatment will in general be very easy. If it should happen that you are not called upon for this complaint until it has arrived at the chronic stage, when the conjunctiva is feebly pouring out pus; the pulse depressed; the skin cold and clammy; the countenance sallow; and, when the constitution has materially suffered from the progress of the disease, an entirely different plan of treatment will be required. Gently stimulating applications should be employed by means of a syringe, so as to cleanse the conjunctiva, and free it from the pus which has collected on its surface, and at the same time stimulate the relaxed vessels. In general it will be necessary to employ tonic remedies, such as bark, for instance; always attending to the due action of the bowels, without which tonics would be useless, and even injurious. With respect to the treatment of the sloughing cornea some nicety will be required. When you have ascertained that the sloughing process is commencing, from the hazy or opaque appearance of the cornea, the antiphlogistic must be changed for a gently stimulating and tonic plan of treatment. Weak astringent collyria should be used, to favor the throwing off of the sloughs. Observe the process of the sloughing from time to time; if there is a firm layer beneath, the patient is going on well, but if the sloughing has a flocculent, soft, ash-colored appearance, in addition to mild stimulants to the part, you should employ tonic remedies, such as bark. The errors in the treatment of purulent ophthalmia may be comprised in two words: they consist either in continuing the depleting plan too long, or not resorting to it sufficiently early.

If the antiphlogistic plan be not adopted at a very early stage of the disease, the tonic treatment will afterwards be of no service; and, on the other hand, if you continue the depleting plan too long, you will check the restorative process, and the beneficial effects which nature would otherwise assist in producing.

Strumous ophthalmia.—Strumous or scrofulous ophthalmia is so called, because it is met with in those persons who are of a scrofulous diathesis. It occurs in children and not unfrequently in adults. In this affection, the inflammation is of the chronic kind from the commencement; the patient cannot bear the least access of light; there is great difficulty of opening the lids, the orbicularis palpebrarum is spasmodically contracted, and so difficult is it for the patient to open the eyes that he can seldom do it. The only way by which this can be done is fixing the head of the patient, when it is a child, between your knees; with the fore finger of the one hand to raise the upper lid, and that of the other to depress the lower, which will give you an opportunity of seeing the eye; but in doing this great caution will be required to prevent eversion of the under lid, or any undue violence to the part. In this complaint

it is of the greatest importance that the cornea should be narrowly watched; for, if the inflammation continues for a long time, ulcers are very apt to form on it. Disorganisation of the different parts of the eye often take place; the cornea, or rather conjunctiva covering it, becomes covered with an opaque capsule, with vessels shooting over the cornea, so as to give it an herpetic appearance; that is, there will be seen, over the cornea, yellow spots, which are deposits of lymph. These open into small ulcers, which are streaked with vessels carrying red blood. The eye becomes very painful, and extremely irritable, and there is often, in this state, intense redness of the conjunctiva. Under these circumstances, similar ulcers form in different parts of the cornea. The formation of these ulcers produces all the symptoms of acute inflammation of the eye, and the organ not unfrequently becomes slowly and gradually disorganised. So long, however, as the cornea continues bright, and of its natural color, there will be no danger to be apprehended from the formation of ulcers.

Treatment.—Although strumous ophthalmia is of the chronic nature, there is still considerable irritation; and, as the constitution in which it occurs is of an unhealthy character, your treatment must be both general and local. First, constitutional. The mild depleting plan must be first adopted, regulated as far as the constitution will bear it; you must remove the symptoms of irritation; open the bowels freely by calomel purges, repeated more or less frequently, as they improve the secretions. Alterative mercurial medicines should then be given, and if necessary they should be combined with rhubarb and magnesia, but not so as to produce watery stools. When the fever becomes diminished, the bowels perform their natural functions, the tongue looks clean, and the skin assumes its healthy feel, you may begin with tonic remedies, and alter the diet, &c. Aromatic bitters, combined with alkalies; light and nutritious diet; warm clothing; moderate exercise; sea-bathing, &c.

As for the treatment of the part affected, it will be right to employ depletion at the onset, and mild astringent applications afterwards. Leeches should be employed; it will also be proper to apply blisters behind the ears, or to the nape of the neck; and blisters in this complaint are no ordinary remedy; warm and moist applications are beneficial; the steam of water containing opium will also prove useful. If any of these applications be used at the onset, they must not be long continued; mild astringent collyria must be had recourse to, and their strength must be regulated by the feelings of the patient. The vinum opii is particularly adapted to the purpose in question. Alteratives are also sometimes necessary.

Psorophthalmia.—Psorophthalmia is an inflammation particularly of that part of the conjunctiva which lines the lids, but it extends sometimes over the whole of the conjunctiva, covering the globe. This complaint is very nearly allied to strumous ophthalmia, because it is in general a consequence of it; it is characterised by the same intolerance of light; the inflammation is of the

chronic kind, and the patient complains of a sensation as if there were some extraneous body in the eye, grit or sand, which gives rise to an effusion of tears. At the origin of the disease there is a glutinous matter secreted on the edge of the lids; ulcers form; and there is often great difficulty in separating the lids from one another. By this means matter lodges on the lids, and tends to keep up the irritation of the whole of the part; the redness sometimes extends down the cheek, and excoriation of the cuticle takes place. There are also numerous other circumstances attending this complaint. This affection of the eye is of difficult management, and is frequently found in persons of a scrofulous diathesis; in children of large towns, who are ill fed and badly clothed, with little attention to cleanliness. It is a complaint very obstinate in its cure; and, if relieved, it generally returns and becomes as bad as ever. The affection is not, however, confined to the lower classes, but the higher and middling ranks of society are sometimes attacked with it; those who are of the scrofulous diathesis. In schools also it will be found; it frequently arises from the irritating matter being applied to the lid, which may be conveyed from one to another by using the same towel, or in some such way.

Treatment.—The treatment of psorophthalmy does not essentially differ from that of the strumous; it is an inflammation without power; one of the atonic kind. Your remedies must be both constitutional and local. Depletion must not be pursued to any extent. It will be right, when any symptoms of irritation are present, to remove them by the application of leeches, and gently opening the bowels by mild aperients, combined with mercurial medicines, such as calomel, the hydrargyrus cum cretâ, or the blue pill, and in quantities so as to give tone to the system. When any febrile excitement that may have existed is removed, begin with tonic remedies; that is, when the skin is clean, and the secretions from the bowels are regular in their quantity and quality. The applications to the parts should consist of stimulants, and the best form in which they can be employed is that of ointment. Any of the milder stimulating mercurial ointments will do; and their degree of strength must be regulated by the effect on the eye. The use of the vinum opii will be attended with beneficial results, and the application of blisters will have an universally good effect, but they should always be healed immediately, and repeated again if required. The consequences of inflammation of the eye requiring distinct notice, and which are accompanied with an equal or less inflammation of the conjunctiva, and kept up or excited by attendant circumstances, are now to be spoken of.

Nebula.—This complaint is so called from the nebulous or cloudy appearance of the transparent part of the eye, which is produced by deposits of lymph into the conjunctiva covering the cornea. The membrane or layer stretched over the cornea will vary according to the more or less relaxed state of the vessels of the conjunctiva, which will be seen carrying red blood to the

part. The veins corresponding to the nebulous parts will become turgid and prominent.

Treatment.—The inflammation in this affection is generally of the chronic kind, and arises from a relaxed state of the vessels, which require stimulating applications, in order that they may recover their tone and convey the blood unimpededly. If the vessels be stimulated, the blood will be likely to flow through the veins; the absorbents will be excited, and remove the effused lymph. If there is considerable inflammation, it must be removed by active means; and in these cases it will be proper to deplete. Care must be taken that in the treatment of this complaint, no undue degree of stimulus be employed; if there should be inflammation it will be increased, and the complaint be as bad as ever. By stimulating applications, the cornea will frequently be restored to the same transparency as before the attack. A good stimulus, which may be used, is one with the sulphate of zinc, containing about a grain to an ounce of water, gradually increased in strength.

Pustules.—Pustules are generally seated at the junction of the transparent with the opaque cornea; but they sometimes occur in the cornea itself, or on the conjunctiva covering it, or the ball. They are seated in different parts. The appearances they present, at first, are red or yellowish spots arising from a deposit of lymph in those parts, and are slightly elevated. There is considerable turgescence of the vessels around them. If they occur on the cornea, it will be nebulous and opaque; the vessels round the cornea will be seen distended, carrying red blood, and having a radiated disposition. If the lymph secreted in this complaint is not absorbed, the pustules break, matter escapes, and ulcers form in their place. Sometimes there is only one of these ulcers, frequently two, one on each side of the cornea, just at the junction of the transparent with the opaque cornea, and occasionally the cornea is encircled by them. They are very difficult to cure, and easily re-produced.

Treatment.—As for the treatment which pustules require, if there should be much inflammation you must deplete; but, as the inflammation is of the tonic kind, depletion must not be pursued to too great an extent at the outset. The system must be invigorated by tonic remedies, and tone given to the vessels of the part. First, apply leeches, not in too large numbers; evacuate the bowels by mild aperients; and attend to the secretions; blisters will be useful if the sight be affected. When the state of the bowels has been regulated, you must begin with tonic remedies, and as early as possible with astringent collyria, and the best is the vinum opii.

Fungus of the conjunctiva.—This appearance of the conjunctiva is the result of purulent ophthalmia, and occurs in diseased persons. The conjunctiva becomes loose and red, the vessels turgid with blood, and there is a fold of this membrane on the inside of the lids, which produces considerable irregularity on its surface; a morbid secretion is kept up on the part, and not un frequently eversion of the lids is the result. Extraneous bodies often enter the eye

and disturb it considerably. To prevent this, and remedy the complaint, the loose portion of the conjunctiva should be removed, which is a very easy operation; an assistant holding the lid, you, by means of a pair of curved scissors, remove it. As to the after treatment, you must keep down inflammation, should it appear, by the means already recommended.

Granulations of the conjunctiva.—These are nothing more than loose irregularities of this membrane, where it lines the lids. These projections continue to pour out a morbid secretion, which stimulates and irritates the whole eye; the palpebral conjunctiva becomes altered in its texture, and its surface is covered with a fleshy elevation, having the exact appearance of granulations. These granulations covering the surface of the conjunctiva lining the lids, are constantly rubbed over the globe of the eye whenever it moves, producing pain and irritation, and keeping up morbid secretion, and, in fact, giving rise to chronic ophthalmia.

Treatment.—Granulations of the conjunctiva, if not removed or remedied, produce ultimate blindness. Cases of this complaint are difficult to cure; and the remedies you are to use are, caustic applications and the division of the varicose and enlarged vessels. These may be aided by setons, issues, blisters, and attention to the general health.

Encanthis.—This consists in an alteration of the structure of the caruncula lachrymalis, and neighbouring semilunar fold of the conjunctiva. In this complaint the caruncula is enlarged; at the commencement it has a granulated appearance, which it loses as it increases, and then becomes similar to a hazel nut, being ash-colored and streaked with varicose vessels. This enlargement or excrescence prevents the lids from closing, and allows extraneous matter to enter, which keeps up inflammation of the eye, and it also presses on the puncta lachrymalia, and turns them out of their place: the tears, thus prevented from getting into the lachrymal sac, are effused on the cheek.

Treatment.—The best treatment you can adopt for the cure of this complaint is the entire removal of the diseased part. The operation should be thus performed:—an assistant is to raise the lid, you then take up the tumor with a pair of forceps, and remove it with a pair of curved scissors with convex edges. When this complaint has not assumed the malignant form, it is always remediable by excision. Never operate, however, when the encanthis has become of the malignant kind, and put on the cancerous appearance. This will be known by the dull red color of the excrescence, its excessive hardness, lancinating pains extending to the eye-ball and forehead, particularly when touched, foul ulcers with irregular edges, having all the appearance of cancer in other parts of the body.

Pterygium.—This is always of the triangular shape, and may be divided into the membranous and fleshy.

Membranous pterygium.—This kind has the appearance of a thin film of minute vessels converging towards the cornea. The usual seat of this affection is towards the inner canthus, that

is, with the base at the canthus, and the apex against the cornea. It is always of a triangular shape, and the vessels proceed from the base to the apex.

Fleshy pterygium.—The fleshy pterygium differs from the membranous, and is more vascular. They first appear of a yellowish color; then the vessels running through them become large, and they have a red appearance; but always retain their triangular shape.

Treatment.—When a pterygium has proceeded far on the transparent part of the eye, the only treatment to adopt will be the removal of a part of the pterygium. This consists simply in raising the membrane as near as you can to the cornea, and cutting it through whilst suspended. When the pterygia are fleshy, more care must be taken in dividing them; they must be divided more to the margin of the cornea, and turned back from the apex towards the base.

2. *Inflammation and ulceration of the cornea.*—At the outset, in inflammation attacking the transparent cornea, there is a hazy appearance, the cornea loses its natural lustre, and in a short time there may be discovered on its surface vessels carrying red blood, and then the symptoms will be the same as those of inflammation in general; the patient will complain of intolerance of light, and also have effusion of tears. If the inflammation of the cornea should continue, matter very frequently forms between its lamellae, and the appearance which it then assumes is called onyx, or unguis, from its resemblance to a nail; the matter is to be very distinctly seen in the transparent part of the eye, and gradually extends till it occupies one-third or fourth of the cornea. If you place the eye in profile you can generally observe yellow spots, which are usually seated at the anterior part of the cornea; and if you employ gentle pressure with a probe, the fluid may be felt fluctuating within. In the various positions of the head the matter does not shift its situation, but remains in the same spot. By proper treatment the matter often becomes absorbed; but it not unfrequently makes its way externally, or an opening is formed internally, and the matter then is effused into the anterior chamber of the eye.

Ulceration.—Ulceration of the cornea is the common consequence of inflammation of the cornea; but it is very frequently produced by the contact of matter in purulent ophthalmia; or, in fact, any irritating substance, mechanical or chemical, that may be introduced into the eye. The inflammation produces the formation of pus; this breaks and an ulcer is formed.

In ulcers of the cornea you will find the edges rugged, uneven, and elevated, the ulcer itself having an ash-colored appearance, and the patient complaining of great pain; there will also be a discharge of a good deal of acrid and irritating matter. In general there will be no difficulty in distinguishing ulcers of the cornea; all you have to do is to put the eye in profile and take a side view of this organ, and you will see the ulcer with the appearances I have described. The situation of ulcers of the cornea varies; as also do the ulcers vary in their appearance.

Treatment.—The treatment required in inflam-

zation of the cornea does not materially differ from that of inflammation of the conjunctiva, or any other part of the eye. You must rely upon the efficacy of a strict antiphlogistic plan, and, when the acute inflammation has been subdued, on the use of mild astringent collyria. When ulcers form in any part of the cornea it will be proper to use active means, if they are accompanied with acute inflammation; but most frequently they are accompanied by chronic ophthalmia, and have a disposition to spread rather than heal. When they are of a spreading disposition astringent lotions will be of great service; but of all remedies in ulcers of the cornea the nitrate of silver is the one on which you are to depend: it is generally used in the state of solution, about two grains to an ounce of water; or it may be better to begin with a grain to an ounce, regulating the strength in proportion to the degree of irritation it may produce. When ulcers of the cornea are attended with acute inflammation, it will be necessary to employ bleeding by leeches before the use of astringents, and at the same time to keep the bowels regular by mild aperients. During the progress of the ulcers it will be necessary to watch them very closely, and examine them frequently; but in doing so great caution must be used lest the eye-lids become everted. When ulcers of the cornea heal it is by cicatrization, as in any other part of the body. The specks which are left upon cicatrization are nothing more than rounded spots of coagulable lymph, and are denominated leucoma or albugo; and in these cases the rays of light are not prevented entering the eye, except when the spots are on the axis of vision.

Staphyloma.—In this disease the cornea becomes opaque, considerably elevated, and altered in texture. It frequently comes on after small pox, and is one of the sequelæ belonging to that formidable complaint. In staphyloma the eye-lids are prevented from being closed; there is perpetual irritation kept up by friction of the palpebræ on the ball. By the separation of the lids extraneous bodies often enter the eye, irritation is produced by the friction of the lids and eye-lashes, and thus a considerable degree of inconvenience is produced to the patient, and the eye kept in a state of chronic ophthalmia; and the sound eye becomes sympathetically affected. The iris often protrudes; the vitreous humor is altered in texture; and the crystalline lens is projected forwards.

Treatment.—In this complaint nothing can be done for the restoration of sight; and the only plan of treatment will be to remove the staphylomatous part, so as to return the eye within the orbit, and permit the use of an artificial eye. The operation is exceedingly simple: the surgeon first passes a needle with a ligature through the staphylomatous part, in order to steady the eye; and then, with the other hand, takes the cornea knife, and removes as much of the projecting part as may be necessary; the operation gives little pain; it generally happens that the iris adheres to the cornea, and that a portion of it is removed. The crystalline lens escapes, together with a portion of vitreous humor, and the eye collapses, so that when the part is healed an artificial eye may be worn.

Iritis.—Inflammation of the iris is a peculiar and specific inflammation, attended with symptoms which, in some cases, are with difficulty recognised. In looking into the eye, you see the iris changed in color, or having a brownish hue, or rather a reddish-brown color (this however varies according to the natural color of the iris), from the increased number of vessels on its surface carrying red blood. The iris itself is altered in texture, being puckered and thickened. These appearances are soon removed, and deposits of yellow lymph, resembling yellow tubercles, will be seen on the iris, the pupil becomes irregular and altered in shape, and the pupillary margin of the iris thickened and turned back towards the posterior chamber. These are the principal symptoms by which you recognise iritis; but there are many other marked appearances.

Iritis is not unfrequently accompanied by inflammation of the tunics of the eye, which has been called *ophthalmitis*, or deep seated inflammation of the globe of the eye. But for the treatment and further description of this very usual variety, we must refer to Mr. Castle's Manual. For cataract see CATARACT.

SECT. III.—LITHOTOMY.

This operation was practised by the ancient Egyptian surgeons under the Ptolemies, especially Ammonius Alexandrinus, and afterwards at Rome by Megeles, and is described particularly by Celsus. It was then a very simple operation, and performed thus:—The presence of a stone being ascertained by a strait sound, the rectum was emptied by an injection, and the patient directed to walk about, as so to make the stone gravitate to the neck of the bladder; and now the patient was secured, as at present, for the lateral operation; and the operator introduced two, or sometimes even three, fingers of his left hand into the rectum, and, feeling the stone, thrust it forward into the perineum and cut directly upon it by a semilunar incision transverse, and having its ends pointing to the hips; then a smaller one, at the deepest part of the first, in the same direction, till it reached the stone, which either started out, or was brought out by a hook for the purpose. There are several objections to this operation. 1. The same parts are not always cut, as that must depend upon the degree of force with which the operator protrudes the stone. 2. The urethra may be altogether divided from the prostate. 3. If the bladder be much pushed forward, it may be divided thus transversely, behind the prostate, so including the vesicula seminales. This operation, together with surgery and medicine, was entirely lost in the dark ages, except by quacks; but it was known to and practised by La Raoux, at Paris, 140 years ago. This operation proved much too simple for the barbarous physicians and surgeons of the middle age, as it was practised by many quacks, &c., which deprived them of their fees; and it was this last reason, says Heiston, that induced them to adopt a more complicated operation, which at once increased their own dignity and saved their fees from passing into other hands. This brutal and cruel operation was invented by Johannes

de Romanis, who, it seems, did not dare to practise or publish it; but his pupil Marianus Sanetus published it in 1524, not as his own but his master's invention; and this operation, which neither dared own, was greedily seized on by the profession. It was performed all over Europe for many years thus:—'A groove-staff was first introduced; then the operator, kneeling on one knee, made an incision with a razor along the perineum, on one side the raphe, and, feeling with his little finger for the curve of the staff, opened the membranous part of the urethra; and, fixing the point of his knife in the groove of the staff, gave it an assistant to hold, while he passed a probe along the knife into the groove of the staff, and thus into the bladder. The urine now flowed out and the staff was withdrawn.'

'The operator next took two strong iron probes, called conductors; one named the female, having a groove like a modern director; the other the male, having a probe point corresponding with the groove. The grooved one was first introduced along the probe, then the latter was withdrawn, and the male passed along the groove of the female into the bladder. Then commenced the operation of dilating. The lithotomist took a conductor in each hand, and, by making their shafts diverge, dilated; or, in plain language, tore open, the prostate gland. After this a pair of strong forceps, with a large blade, were used to dilate it still more. Then these were withdrawn, and a blunt gorget introduced; upon this the vials extractors were introduced, and the stone brought out. This operation lasted for many years, till 1097, when a new operation was introduced by a wandering friar, called Frere Jocque, his real name was Jacque Beaulieu, and it appears that he had learned his operation of another quack, and had then wandered over Europe, and at length came to Paris with certificates of his success, and volunteering to operate. He took no fees, but acted for the glory of the Divinity, receiving only enough to afford himself sustenance, and keep his instruments in order. He was authorised by the government to operate in the hospitals of La Charité, and the Hotel Dieu, and, though violently opposed by the profession, seems to have been eminently successful at first; but having no knowledge of anatomy, he did not always cut the same parts, and latterly failed in several instances; so that at last his envious rivals prevailed, and he left Paris and travelled to the provinces and Holland, and, having studied anatomy, operated again with the greatest success. His operation was the

Lateral operation.—He introduced a straight staff into the bladder, and plunging his knife into the side of the perineum near the tuber ischie, about two fingers' breadth from the raphe, cut upon the staff, which served as a guide into the bladder, cutting upwards from the anus. He never withdrew his knife till he had made a sufficient opening for the stone, which he withdrew by a pair of forceps in a rough manner, using sometimes a director, but more commonly his finger. This operation was imitated and practised by Raw, Marechal, Bamber, and Chesselden, which last modified it in several ways, and at last performed it as we perform it at present.

Sir Astley Cooper says, 'In the lateral operation of lithotomy, you are to begin your incision a little on the left side of the raphe, immediately below the symphysis pubis, and carry it obliquely downwards and outwards to midway between the anus and tuberosity of the ischium, and the termination of the incision should be opposite to the centre of the anus. Before you commence the incision you should draw aside the raphe towards the ramus of the ischium on the right side. Never begin an operation without having first reflected well on what you are going to do; and, in making incisions through the skin, you should, before you apply the knife, mark out with your eye the course which such incisions should take, and the precise point where they should terminate. Well then, the first cut through the skin, made in the direction just mentioned, penetrates the skin and cellular substance, and lays bare the accelerator urinæ; you then with the fingers of your left hand push or draw the bulb of the penis under the ramus of the ischium on the right side, so that the next incision will pass between the bulb and crus penis of the left side; there is no necessity in reality for cutting the bulb, and it should therefore be avoided; well, carrying your knife forward between the bulb and crus, you divide the accelerator urinæ, and this you should do completely, for if you permit any portion of its fibres to remain undivided, particularly at the upper part, if the stone should be at all large, you will find that their contractions would very much increase the difficulty of withdrawing the stone; immediately that the accelerator urinæ has been cut through, you expose the transversus perinei; you are then to feel for the groove of the staff with the nail of the index finger of the left hand, and, having fully satisfied yourself of its situation, you are to cut through it into the membranous part of the urethra by means of the same scalpel with which you made the other incisions—and then, fixing the beak of the gorget in the groove of the staff, you are to bring down towards you the handle of the latter instrument, while at the same moment you push the gorget into the bladder, with its point directed upwards, and its handle of course somewhat depressed. I give you this last direction for the purpose of preventing the dreadful accident of the gorget slipping and passing between the bladder and rectum, instead of its entering the former viscus.'

An instrument for dividing the prostate and bladder has of late been used with success in the lateral operation of lithotomy: it is called the bistourie caché; it was invented by Cosme, a French surgeon, about 100 years since; it consists of a knife enclosed in a sheath which, after being introduced into the bladder and turned with its edge outwards and downwards, cuts its way out when withdrawn. Many operators use a knife to open the bladder, and it answers in young persons; but, in old ones with diseased prostate, it does not cut enough to admit the stone.

The high operation, lately recommended by Mr. Corpue and practised by sir Everard Home, was first made known to the world in 1561, by Pierre Franco, who, in his Treatise on Hernia,

says he once performed it on a child with very good success, but discourages the farther practice of it. After him Rossetus recommended it, with great zeal, in his book entitled *Partus Cæsarius*, printed in 1591; but he never performed the operation himself. Monsieur Tolet makes mention of its having been tried in the Hôtel-Dieu; but, without entering into the particular causes of its discontinuance, says only that it was found inconvenient. About the year 1719 it was first done in England by Mr. Douglas; and after him practised by others.

The patient being laid on a square table, with his legs hanging off and fastened to the sides of it by a ligature passed above the knee, his head and body lifted up a little by pillows so as to relax the abdominal muscles, and his hands held steady by some assistants; inject through a catheter, into the bladder, as much barley-water as he can bear, which, in a man, is often about eight ounces, and sometimes twelve. The bladder being filled, an assistant, in order to prevent the reflux of the water, must grasp the penis the moment the catheter is withdrawn, holding it on one side in such a manner as not to stretch the skin of the abdomen; then with a round-edged knife make an incision about four inches long between the recti and pyramidal muscles, through the *membrana adiposa* as deep as the bladder, bringing its extremity almost down to the penis; after this, taking a crooked knife, continue the incision into the bladder, carrying it a little under the *os pubis*; and immediately upon the water's flowing out, introduce the fore-finger of your left hand, which will direct the forceps to the stone. Sabatier wisely condemns making the cut in the bladder from below upward lest the knife injure the peritonæum.

Although this is one of the easiest and to all appearance the safest method of operating, several objections soon brought it into disuse. 1. The irritation of a stone often causes such a thickened and contracted state of the bladder that this viscus will not admit of being distended so as to rise above the pubes. 2. If the operator should break the stone, the fragments cannot be easily washed away, and remaining behind will form a nucleus for a future stone. 3. Experience has proved that the high operation is very commonly followed by extravasation of urine, attended with suppuration and gangrenous mischief in the cellular membrane of the pelvis. This happens because the urine more readily escapes out of the wound in the bladder than through the urethra; and also because when the bladder contracts, and sinks behind the *os pubis*, this wound ceases to be parallel to that in the *linea alba* and integuments, and becomes deeper and deeper. For the prevention of these ill consequences, says Sabatier, it will be in vain to make the patient lie in an horizontal posture and to keep a catheter introduced, as Rousset and Morand recommended: experience has evinced that the bad effects, which we have described, were neither less frequent nor less fatal. 4. The danger of exciting inflammation of the peritonæum. 5. The injection itself is exceedingly painful, and, however slow the fluid be injected, the bladder can seldom be dilated enough to make the oper-

ation absolutely secure; and, when hastily dilated, it is sometimes even burst, or, at least, its tone destroyed. We need not enumerate other inconveniences.

Some of the objections, however, do not apply to certain instances. In many men, we know by searching that their bladder is very large, so that we can run no risk of meeting with it in a contracted state, and, therefore, the objection is of no weight when we are certain that the bladder extends itself a considerable way above the pubes, and will admit a large quantity of injection. Stones are sometimes known to be of large size, and they are less likely to be broken in this than any other mode of lithotomy, so that the objection of the difficulty of extracting small calculi and fragments is less forcible. The excoriations, from the effusion of urine all over the skin near the wound, may be prevented by embrocations, ointment, &c. The abscesses and gangrenes arising from the extravasation of urine in the cellular substance, says an able surgeon, may be very much prevented by the introduction of a cannula, as practised in the puncture of the bladder above the *os pubis*.

Lithotomy in women.—The naturally large size and dilatable nature of the female urethra have suggested the plan of endeavouring to expand this passage by various means, so that a stone in the bladder may be taken out with a pair of forceps, without having occasion to employ any cutting instrument whatsoever. This method was proposed by Douglas nearly a century ago, who not only recommended the use of sponge for the purpose, but also dried gentian root, as being more gradual in its expansion, and better adapted to the object.

Lithotomy on females is much more easy of execution, and less dangerous, than the same operation on the male subject. It may be done in various ways; but the surgeons of the present time constantly follow the mode of making the requisite opening by dividing the urethra and neck of the bladder. A straight staff, or director, is introduced through the *meatus urinarius*; the groove is turned obliquely downwards and outwards, in a direction parallel to the ramus of the left *os pubis*; and a gorget, or knife, is thus conducted into the bladder, and makes the necessary incision. Some operators prefer the lithotome caché, which, after being introduced, is opened as far as is deemed proper, and then drawn out with its edge turned obliquely outwards and downwards.

The French surgeons Louis and Flurant, were the inventors of particular bistouries for dividing both sides of the female urethra at once. The instrument of the former effected this purpose, in passing from without inwards; that of the latter, in passing from within outwards. Flurant's bistoury bears some resemblance in principle to Frère Côme's lithotome caché, or to the cutting forceps, with which Franco used to divide the neck of the bladder. The reason assigned in recommendation of these bistouries, is, that they serve to make a freer opening for the passage of large stones, than can be safely made by cutting only in one direction. At present, however, they are never used.

SECT. IV.—SUPPLEMENTARY VIEW OF DISEASES OF THE SKIN.

In this part of our article we shall, after explaining a few terms of less frequent occurrence touch upon the leading diseases of this species, conceiving that though some writers have spoken of them as pertaining to medicine, they may with greater propriety be enrolled among surgical cases, since they affect the contexture of the body, and may in many occasions be relieved by a manual operation.

But it may not be amiss in the first place to present the reader with Dr. Willan's classification and definitions, which we intend to follow.

CLASSIFICATION.

ORDER I.—PAPULÆ.

Genera.

- Strophulus* (red gum, tooth eruption, &c.)
- Lichen* (spring eruption, scorbutic pimples, &c.)
- Prurigo* (gratelle, or universal itching of the skin).

ORDER II.—SQUAMÆ.

- Lepra* (leprosy of the Greeks).
- Psoriasis* (dry or scaly tetter).
- Pityriasis* (dandriff).
- Ichthyosis* (fish-skin).

ORDER III.—EXANTHEMATÆ.

- Rubeala* (measles).
- Scarlatina* (scarlet fever).
- Urticaria* (nettle rash).
- Roseola* (rose rash).
- Purpura* (purple or scorbutic rash).
- Erythema* (red rash).

ORDER IV.—BULLÆ.

- Erysipelas* (St. Anthony's fire).
- Pemphigus* (vesicular fever).
- Pompholyx* (water-blebs).

ORDER V.—PUSTULÆ.

- Impetigo* (running tetter).
- Ecthyma* (large inflamed pustules).
- Variola* (small-pox).
- Scabies* (itch).
- Porrigo* (scald head honey-comb-scab, &c.)

ORDER VI.—VESICULÆ.

- Herpes* (ring worm, shingles, wild fire, &c.)
- Varicella* (chicken pox, and swine pox).
- Vaccinia* (cow-pox).
- Miliaria* (miliary eruptions).
- Eczema* (heat eruption).
- Aphthæ* (thrush).

ORDER VII.—TUBERCULÆ.

- Phyma* (boils, carbuncles, &c.)
- Verruca* (warts).
- Molluscum* (small soft wens).
- Vitiligo* (white smooth tubercles).
- Acne* (stone-pock, red tuberculated face, &c.)
- Lupus* (or noli me tangere).
- Elephantiasis* (Arabian leprosy).
- Frambæsia* (yaws).

ORDER VIII.—MACULÆ.

- Ephelis* (sun spots).
- Nævus*.
- Spilus*, moles, and other original marks.

1. *Papula*, pimple; a very small and acuminate elevation of the cuticle, with an inflamed base, very seldom containing a fluid, or suppurating, and commonly terminating in scurf.

2. *Squama*, scale; a lamina of morbid cuticle, hard, thickened, whitish, and opaque, Scales, when they increase into irregular layers, are denominated crusts.

3. *Exanthema*, rash, superficial red patches, variously figured, and diffused irregularly over the body, leaving interstices of a natural color, and terminating in cuticular exfoliations.

4. *Bulla*, bleb, a large portion of the cuticle detached from the skin by the interposition of a transparent watery fluid.

5. *Pustula*, pustule, an elevation of the cuticle, with an inflamed base, containing pus.

Four varieties of pustules are denominated in this arrangement, as follows:—

a. *Phlyzaciun*, a pustule, commonly of a large size, raised on a hard circular base, of a vivid red color, and succeeded by a thick, hard, dark-colored scab.

b. *Psycracium*, a small pustule, often irregularly circumscribed, producing but a slight elevation of the cuticle, and terminating in a laminated scab. Many of the psycracia usually appear together, and become confluent; and, after the discharge of pus, they pour out a thin watery humor, which frequently forms an irregular incrustation.

c. *Achor*; and

d. *Favus*. These two pustules are considered by the majority of writers, from the Greeks downwards, as varieties of the same genus, differing chiefly in magnitude. The *achor* may be defined a small acuminate pustule, containing a straw-colored matter, which has the appearance and nearly the consistence of strained honey, and succeeded by a thin brown or yellowish scab. The *favus*, or *κρηρον*, is larger than the *achor*, flatter, and not acuminate, and contains a more viscid matter; its base, which is often irregular, is slightly inflamed; and it is succeeded by a yellow, semi-transparent, and sometimes cellular scab, like a honey-comb; whence it has obtained its name.

6. *Vesicula*, vesicle, a small orbicular elevation of the cuticle, containing lymph, which is sometimes clear and colorless, but often opaque, and whitish or pearl-colored. It is succeeded either by scurf, or by a laminated scab.

7. *Tuberculum*, tubercle, a small, hard, superficial tumor, circumscribed, and permanent, or suppurating partially.

8. *Macula*, spot, a permanent discoloration of some portion of the skin, often with a change of its texture.

The following terms are used in their ordinary acceptance; viz.

9. *Wheal*, a rounded or longitudinal elevation of the cuticle, with a white summit, but not permanent, not containing a fluid, nor tending to supuration.

10. *Furfur*, scurf, small exfoliations of the cuticle, which occur after slight inflammations of the skin, and a new cuticle being formed underneath during the exfoliation.

11. *Scab*, a hard substance, covering superfi

cial ulcerations, and formed by a concretion of the fluid discharged from them.

12. *Stigma*, a minute red speck in the skin, without any elevation of the cuticle. When stigmata coalesce, and assume a dark-red or livid color, they are termed *petechiæ*.

Order I.—*PAPULÆ*. Papulæ, or pimples, appear to originate in an inflammation of the papillæ of the skin, by which these are enlarged, elevated, and indurated, and made to assume more or less of a red color. Sometimes even a slight effusion of lymph takes place, which gives a vesicular appearance to several of the papulæ; but the fluid is re-absorbed without breaking the cuticle, and they terminate for the most part in scurf. The varieties of papulous eruptions are comprehended in this arrangement under three genera; namely, *strophulus*, *lichen*, and *prurigo*.

i. *Strophulus*.—This genus comprises several papular affections, peculiar to infants, which are known by the common appellations of red gum, tooth-eruption, &c. They arise in consequence of the extreme vascularity and irritability of the skin at that period of life, when the constitution is accidentally disturbed by irritation, either in the alimentary canal, the gums, or other parts. As they are not, however, very important objects of medical practice, but interesting only from their occasional resemblance to some of the exanthemata, I shall not dwell upon them at any length. The following varieties are mentioned by Dr. Willan:—1. *Strophulus intertinctus*, the red gum or gown, is characterised by papulæ of a vivid red color, situated most commonly on the cheeks, fore-arms, and back of the hands, but sometimes universally diffused. 2. *Strophulus albidus*. 3. *Strophulus confertus*. 4. *Strophulus volaticus*: not a frequent complaint. 5. *Strophulus candidus*.

ii. *Lichen* is defined by Dr. Willan to be ‘an extensive eruption of papulæ, affecting adults, connected with internal disorder, usually terminating in scurf, recurrent, not contagious.’ The varieties of this eruption are seven.

1. The *lichen simplex* is an eruption of red papulæ, first appearing on the face or on the arms, and extending, in the course of three or four days, to the trunk and lower limbs. It is preceded for a few days by slight febrile irritation, which commonly ceases when the eruption appears. This is accompanied with an unpleasant sensation of tingling, especially in the night: it continues nearly stationary about a week, when its color begins to fade, and the skin soon exhibits numerous scurfy exfoliations, which remain longest about the flexures of the joints. The duration of the complaint varies considerably, however, from ten days to three weeks. 2. *Lichen circumscriptus* is characterised by clusters or patches of papulæ, which have a well-defined margin, and are of an irregularly circular form. 3. *Lichen agrius* is ushered in by febrile symptoms, which are commonly relieved on the appearance of the papulous eruption. The papulæ occur in large patches, are of a high red color, and have a degree of inflammation diffused round them to a considerable extent. They are accompanied by itching, heat, and a painful tingling, which are augmented to a sensation of

smarting and scalding by the heat of the bed, washing with soap, drinking wine, or using violent exercise. The symptoms undergo a daily increase and remission: for they are all greatly diminished in the morning, and recur after dinner. Some small vesicles, filled with a straw-colored fluid, are occasionally intermixed with the papulæ; but they are not permanent. 4. *Lichen lividus* is distinguished by the dark red or livid hue of its papulæ, which appear chiefly on the extremities, and without any accompanying symptoms of fever. The papulæ are more permanent, however, than in the foregoing varieties: and, after their desiccation, the disorder is liable to be prolonged for many weeks by a fresh eruption.

iii. *Prurigo*.—The characteristic symptoms of this genus are, a severe itching, accompanied by an irruption of papulæ of nearly the same color with the adjoining cuticle. It affects the whole surface of the skin, under three varieties of form, as well as some parts of the body locally. 1. *Prurigo mitis* is accompanied by soft and smooth papulæ, somewhat larger, and less acuminated than those of lichen, and seldom appearing red or inflamed, except from violent friction. Hence an inattentive observer may overlook the papulæ altogether: more especially as a number of small thin black scabs are here and there conspicuous, and arrest his attention. These originate from the concretion of a little watery humor, mixed with blood, which oozes out, when the tops of the papulæ are removed, by the violent rubbing or scratching which the severe itching demands.

2. *Prurigo formicans*. This affection differs materially from the preceding, in the obstinacy and severity of its symptoms, although its appearances are not very dissimilar. The itching accompanying it is incessant, and is combined with various other painful sensations; as of insects creeping over and stinging the skin, or of hot needles piercing it.

3. *Prurigo senilis*. The frequent occurrence of prurigo in old age, and the difficulty of curing it, have been the subject of universal observation. The sensation of itching, in the prurigo of that period of life, is as intolerable and more permanent than in the *P. formicans*; and the appearances which it exhibits are very similar, except that the papulæ are for the most part larger. The comfort of the remainder of life is sometimes entirely destroyed by the occurrence of this disease.

Order II.—*SQUAMÆ*. Scaly diseases.—Those opaque and thickened laminae of the cuticle, which are called scales, are commonly produced by some degree of inflammation of the true skin, over which they are formed; but occasionally, as in the slighter forms of pityriasis, the cuticle alone, or with the rete mucosum, appears to be in a morbid condition. If the definition be carefully attended to, scales will not be confounded with the scabs succeeding confluent pustules and vesicles, or superficial ulcerations. The four genera of scaly diseases are lepra, psoriasis, pityriasis, and ichthyosis.

i. *Lepra*.—The term lepra is here appropriated solely to the leprosy of the Greeks, as described

by the more accurate of those writers. It is characterised by 'scaly patches, of different sizes, but having always nearly a circular form.'

1. *Lepra vulgaris*, the ordinary species of the disease in this country, commences with small, round, reddish, and shining elevations of the skin, at first smooth, but within a day or two exhibiting thin white scales on their tops. These gradually, sometimes rapidly, dilate to the size of half-a-crown, still retaining their oval or circular form, and are covered with shining scales, and encircled by a dry, red, and slightly elevated border. In some cases these scales accumulate, so as to form thick prominent crusts. If the scales or crusts are removed, the skin appears red and shining, being very smooth, and free from the cuticular lines in the beginning, but marked, in the advanced stages, with long deep lines and reticulations, not always coinciding with those of the adjoining surface.

ii. *Lepra alphoides*. This is a less severe form of the disease than the preceding. It differs chiefly in the small size of the patches, which seldom extend beyond the diameter of a few lines, or become confluent, in the minuteness and greater whiteness of the scales, and in its limitation to the extremities. This variety of lepra is most common in children. It is tedious and difficult of cure, like the former, and requires similar treatment.

2. *Psoriasis*.—The psoriasis, or scaly tetter, occurs under a considerable variety of forms, exhibiting in common with lepra, more or less roughness and scaldiness of the cuticle, with a redness underneath. It differs, however, from lepra in several respects. Sometimes the eruption is diffuse and continuous, and sometimes in separate patches of various sizes; but these are of an irregular figure, without the elevated border, the inflamed margin, and the oval or circular outline of the leprous patches: the surface under the scales is likewise much more tender and irritable in general than in lepra; and the skin is often divided by rhagades or deep fissures. It is commonly accompanied by some constitutional disorder, and is liable to cease and return at certain seasons.

1. The psoriasis guttata is a sort of connecting link between this genus and lepra, the little patches being distinct, and small (seldom exceeding two or three lines in diameter), but with an irregular circumference, and the other peculiar characters just described. They appear on almost every part of the body, and even on the face: but in the latter situation they exhibit only a redness and roughness, without scales. This eruption is most common in the spring, at which season it is liable to recur for several years. It is preceded by general pains, and slight feverishness. In children it often spreads rapidly over the body in two or three days; but in adults its progress is gradual and slow.

2. The psoriasis inveterata is the most severe modification of the complaint, beginning in separate irregular patches, which extend and become confluent, until at length they cover the whole surface of the body, except a part of the face, or sometimes the palms of the hands and soles of the feet, with a universal scaldiness,

interspersed with deep furrows, and a harsh, stiff, and thickened state of the skin.

iii. *Pityriasis*.—The pityriasis is a very superficial affection, characterised by irregular patches of thin scales, which repeatedly exfoliate and recur, but which never form crusts, nor are accompanied with excoriations. It is not contagious. It occurs under three or four varieties of form.

1. The pityriasis capitis, which in infants is called dandruff, appears in a slight whitish scurf along the top of the forehead and temples, but in larger, flat, separate semi-transparent scales on the occiput. A similar affection occurs on the scalp of aged persons.

2. The pityriasis rubra occurs most frequently in advanced life, and is the result of a slight inflammation of the portions of the skin affected, somewhat resembling in this respect the psoriasis diffusa. The cuticle is at first only red and rough, but soon becomes mealy or scurfy, and exfoliates, leaving a similar red cuticle underneath, which undergoes the like process; the scaldiness becoming greater as the exfoliation is repeated. This complaint is attended with a dry and unperspiring surface, a troublesome itching, and a feeling of stiffness. There is also a general languor and restlessness. When the redness and scales disappear, the patches are left of a yellowish or sallow hue. But the whole process is liable to be repeated at short intervals, and the disease to be thus greatly prolonged.

3. The pityriasis versicolor is most remarkable for the chequered and variegated discoloration of the cuticle which it exhibits. It appears mostly about the breast and epigastrium, and sometimes on the arms and shoulders, in brown patches of different shades, variously branching and coalescing, and interspersed with portions of the natural hue.

iv. *Ichthyosis*.—The ichthyosis, or fish-skin disease, is characterised by a thickened, hard, rough, and in some cases almost horny texture of the integuments of the body, with some tendency to scaldiness, but without the deciduous exfoliations, the distinct and partial patches, or the constitutional disorder, which belong to lepra and psoriasis.

1. *Ichthyosis simplex*. In its commencement this disease exhibits merely a thickened, harsh, and discolored state of the cuticle, which appears, at a little distance, as if it were soiled with mud. When further advanced, the thickness, hardness, and roughness, become much greater, and of a warty character, and the color is nearly black.

2. *Ichthyosis cornea*. Several cases of a rigid and horny state of the integuments, sometimes partial, but sometimes extending nearly over the whole body, have been recorded by authors; and occasionally such a condition of the cuticle has been accompanied with the actual production of excrescences of a horny texture. These however, are rare occurrences.

Order III.—EXANTHEMATATA. Rashes. The term exanthema, efflorescence, appears to have been used by the Greek writers in a very general sense, equivalent to that of our word eruption;

and it has been employed, in this acceptation, by many modern authors. The nosologists, however, have limited it to those eruptions which are accompanied with fever, and which have their regular periods of efflorescence and decline.

i. *Rubeola*. Measles. The rash, in the measles, appears usually on the fourth, but sometimes on the third, fifth, or sixth day of a febrile disorder, and, after a continuance of four days, gradually declines with the fever. The disease commences from ten to fourteen days after the contagion has been received, and appears under three varieties of form.

1. *Rubeola vulgaris*. The diagnosis of this rash is thus summed up by Dr. Bateman. It first shows itself in distinct, red, and nearly circular spots, somewhat less than the ordinary areolæ of flea-bites. As these increase in number, they coalesce, forming small patches, of an irregular figure, but approaching nearest to that of semi-circles or crescents. These patches are intermixed with the single circular dots, and with interstices of the natural color of the skin: on the face they are slightly raised, so as to give the sensation of inequality of surface to the finger passed over the cuticle. The whole face, indeed, is often sensibly swelled at the height of the eruption; and occasionally the tumefaction of the eyelids is so great as to close the eyes for a day or two, as in the small pox: but on the other parts of the body they are not sensibly elevated.

ii. *Scarlatina*.—The scarlet fever is characterised by a close and diffuse efflorescence, of a high scarlet color, which appears on the surface of the body, or within the mouth and fauces, usually on the second day of fever, and terminates in about five days.

1. *Scarlatina simplex*. The scarlatina simplex consists merely of the rash, with a moderate degree of fever. The day after the slight febrile symptoms have appeared, the efflorescence begins to show itself, about the neck and face, in innumerable red points, which, within the space of twenty-four hours, are seen over the whole surface of the body. These, as they multiply, coalesce into small patches, but, on the following day (the third), form a diffuse and continuous efflorescence over the limbs, especially round the fingers.

2. *Scarlatina anginosa*. A variety of the preceding, accompanied with an inflammation about the fauces.

3. *Scarlatina maligna*. This form of scarlatina commences like the last, but is attended with very dreadful symptoms. The eyes are dull and suffused with redness, the cheeks exhibit a dark-red flush, and the mouth is encrusted with a black or brown fur. The ulcers in the throat are covered with dark sloughs, and surrounded by a livid base; and a large quantity of viscid phlegm clogs up the fauces, impeding the respiration, and occasioning a rattling noise, as well as increasing the difficulty and pain of deglutition.

iii. *Urticaria*.—*Urticaria febrilis*. Attended with fever, headach, and sickness in the stomach.

Urticaria evanida. Distinguished by the alternating appearance and reappearance of the wheals, as under the influence of various causes.

Urticaria perstans. Its specific name expresses its characteristic.

Urticaria conferta. Wheals coalescing into patches.

Urticaria subcutanea. Marked by a violent and almost constant tingling of the skin.

Urticaria tuberosa. Wheals forming hard tuberosities.

iv. *Roseola*.—This efflorescence is mostly symptomatic, and occurs in connexion with different febrile complaints. It is rose-colored, without wheals or papulæ, and not contagious.

Roseola æstiva commences upon the face, and is distributed in small patches over various parts of the body.

Roseola autumnalis occurs in children in distinct, circular, or oval patches.

Roseola vaccina, *Roseola miliaris*, *Roseola variolosa*, *Roseola infantilis*. } The signification of these terms conveys an idea of the principal characteristics.

v. *Purpura* is known by an efflorescence consisting of small, distinct, purple specks and patches, attended with general debility, but not always with fever.

1. *Purpura simplex*. In this variety there is an appearance of petechiæ, without much disorder of the constitution, except languor, and loss of the muscular strength, with a pale or sallow complexion, and often with pain in the limbs. The petechiæ are most numerous on the breast, and on the inside of the arms and legs, and are of various sizes, from the most minute point to that of a flea-bite, and commonly circular. They may be distinguished from recent flea-bites, partly by their more livid or purple color, and partly because, in the latter there is a distinct central puncture, the redness around which disappears on pressure. There is no itching or other sensation attending the petechiæ.

2. *Purpura hæmorrhagica* is considerably more severe; the petechiæ are often of a larger size, and are interspersed with vibices and ecchymoses, or livid stripes and patches, resembling the marks left by the strokes of a whip or by violent bruises.

3. *Purpura urticans*.

4. *Purpura senilis*. I give this appellation to a variety of the complaint of which I have seen a few cases, occurring only in elderly women. It appears principally along the outside of the fore arm, in successive dark purple blotches, of an irregular form and various magnitude.

iv. *Erythema* is defined by Dr. Willan to be 'a nearly continuous redness of some portion of the skin, attended with disorder of the constitution, but not contagious.' Dr. Willan has described six varieties, which will include all the ordinary forms of the efflorescence. In some of them, as will appear from their titles, the surface is more or less elevated at some period of its course, approximating to the papular or tubercular tumors; but these are obscurely termed, and soon subside, leaving the redness undiminished.

1. Erythema fugax consists of red patches, of an irregular form, and short duration, resembling the redness produced from pressure.

2. Erythema laeve exhibits a uniformly smooth, shining surface, and chiefly appears on the lower extremities, in confluent patches, and is generally accompanied by anasarca.

3. Erythema marginatum.

4. Erythema papulatum occurs chiefly on the arms, neck, and breast, in extensive irregular patches, of a bright red hue, presenting not an inelegant painted appearance. For a day or two, before the color becomes vivid, the surface is rough or imperfectly papulated.

Order IV.—BULLE. The large and often irregular vesications, which are termed bullæ, discharge a watery fluid when they break; and the excoriated surface sometimes becomes covered with a flat yellowish or blackish scab, which remains till a new cuticle is formed underneath; and sometimes is converted into an ulcer, which does not readily heal.

i. *Erysipelas*, considered under the head of *Inflammation*.

ii. *Pemphigus*.—Authors are not agreed about the distinct nature of those diseases which have been described under this appellation.

iii. *Pompholyx*.—An eruption of bullæ appearing without any inflammation round them, and without fever, and therefore, differing most materially from the pemphigus described by nosologists, Dr. Willan applied the appellation of pompholyx.

1. *Pompholyx benignus* exhibits a succession of transparent bullæ, about the size of a pea, or sometimes of a hazel nut, which break in three or four days, discharge their lymph, and soon heal. They appear chiefly on the face, neck, and extremities; and occur in boys in hot weather, in infants during dentition, and in young persons of irritable habit from eating acrid vegetable substances, or from swallowing a few grains of mercury.

Order V.—PUSTULE. Pustules originate from an inflammation of the skin, and the consequent partial effusion of purulent matter under the cuticle, by which the latter is elevated into small circumscribed tumors. Sometimes several of these elevations arise upon a common inflamed surface; but most frequently the inflammation of the base of each is distinct and circumscribed. They often terminate in a scabby incrustation, varying in hardness according to the various tenacity of the contained fluid; and sometimes in superficial ulceration.

i. *Impetigo*, humid or running tetter. This eruption is characterised by the appearance of the small pustules denominated psydracia. It is not accompanied by fever, not contagious, nor communicable by inoculation.

1. *Impetigo figurata* deserves particular notice, because in its early stages it is very apt to be mistaken for the scabies. It appears in circumscribed patches, of various figure and magnitude, which are usually smaller and more circular on the upper, and larger, oval, and irregular on the lower extremities. The patches consist at first of clusters of the yellow psydracious pustules, set close together, and surrounded by

a slight inflammatory border; the whole being somewhat raised, but the pustules not very prominent or acuminate. In a few days the pustules break and discharge their fluid; the surface becomes red and excoriated, shining as if it were stretched, but exhibiting numerous minute pores, from which a considerable ichorous discharge is poured out, accompanied with much troublesome itching, heat, and smarting. The discharge soon concretes partially into thin yellowish or greenish scabs; but still continues to ooze from under the scab which it forms. In the course of three or four weeks, as the quantity of the discharge diminishes, the scabs dry and fall off, leaving the surface of the cuticle red, rough, and somewhat thickened, and at the same time extremely brittle, and liable to crack and to be excoriated; so that the ichorous discharge and scabbing are easily reproduced, and the disease is often thus much prolonged in its duration. Occasionally fresh crops of the psydracious pustules re-appear, as at the commencement; and the whole course of eruption is repeated.

2. *Impetigo sparsa* differs from the preceding chiefly in form.

3. *Impetigo erysipelatodes*.

4. *Impetigo scabida*. We shall insert an account of this species as observed among the natives of the Sandwich Islands, where this genus is very common.

'Pupu, a cutaneous disease common among those who neglect the cleanly state of their persons, and expose the surface to the inclemencies of the weather. The categorematic pu signifies any kind of effervescence or bubbling up, and is well expounded by *ὄλω*, the root of phlyzacia; but, as these pustules are not accompanied by any heat or febrile symptoms, they properly come under the denomination of psydracious, constituting a particular kind of cutaneous malady called impetigo or running tetter. This disease is often mistaken by foreign visitors for the itch; but differs from it in not being contagious, and in having the lamellated scabs, which leave large deep red aveolæ behind them. The easy method of cure always makes it obvious that this affection differs essentially from the itch on one hand, and the porrigo on the other, though my friend Dr. Pearson of Macas, judging from report, referred it to the latter; for, by keeping the body clean and covered, it gradually disappears; and since the people have adopted the European mode of culture, its appearance has become less general than formerly. I have noticed that those poor men who work a great deal in those artificial swamps called taro-patches are peculiarly exposed to its virulence, and I have sometimes thought that the origin of this disease might be attributed to an irritation which the acrid qualities of the areum, or as it is now called calladium, might have at first occasioned in the skin, till by frequent occurrence it grew, by disposing the constitution to contract this morbid habit, to its present state of violence. It often attacks the legs or ancles in form of large scaly tumors, and in its worst form cracks and emits an ichorous discharge. I have sometimes seen the legs of a dropsical person covered, as it were, with graveas of one entire scab, and was

in its worst condition whilst the water was accumulating; but, after the operation of tapping, it would scale off and present for a time only a deep red, and hardened surface.

ii. *Porri*go. Ringworm of the scalp, scalled head, etc.—The porri^go is a contagious disease, principally characterised by an eruption of the pustules denominated favi and achores unaccompanied by fever. The several appearances which the disorder assumes are reducible to five or six specific forms.

1. The porri^go larvalis, or crusta lactea of authors, is almost exclusively a disease of infancy. It commonly appears first on the forehead and cheeks, in an eruption of numerous minute and whitish achores, which are crowded together upon a red surface. These pustules soon break, and discharge a viscid fluid, which concretes into thin yellowish or greenish scabs. As the pustular patches spread, the discharge is renewed, and continues also from beneath the scabs, increasing their thickness and extent, until the forehead, cheeks, and even the whole face, become enveloped, as by a mask (whence the epithet larvalis), the eyelids and nose alone remaining exempt from the incrustation.

2. Porri^go furfurans. In this form of the disease, which commences with an eruption of small achores, the discharge from the pustules is small in quantity, and the excoriation slight; the humor, therefore, soon concretes, and separates in innumerable thin laminated scabs, or scale-like exfoliations.

3. The porri^go lupinosa is characterised by the formation of dry circular scabs, of a yellowish-white color, set deeply in the skin, with elevated edges and a central indentation or depression, sometimes containing a white scaly powder, and resembling, on the whole, the seeds of lupines.

4. The porri^go scutulata, popularly termed the ringworm of the scalp, appears in distinct and even distant patches, of an irregularly circular figure, upon the scalp, forehead, and neck. It commences with clusters of small light-yellow pustules, which soon break and form thin scabs over each patch, which, if neglected, become thick and hard by accumulation.

5. Porri^go decalvans, the $\alpha\lambda\omega\pi\eta\zeta$ of the Greeks.—This singular variety of the disease presents no appearance whatever, except patches of simple baldness, of a more or less circular form, on which not a single hair remains, while that which surrounds the patches is as thick as usual. The surface of the scalp, within these areas, is smooth, shining, and remarkably white. It is probable, though not ascertained, that there may be an eruption of minute achores about the roots of the hair, in the first instance, which are not permanent, and do not discharge any fluid.

6. Porri^go favosa. This species of the disorder consists of an eruption of the large, soft, straw-colored pustules, denominated favi. These are not in general globular with a regularly circular margin, but somewhat flattened, with an irregular edge, and surrounded by a slight inflammation. They occur on all parts of the body; sometimes on the scalp alone, and sometimes on the face, or on the trunk and extremities only;

but most commonly they spread from the scalp, especially from behind the ears to the face, or from the lips and chin to the scalp, and occasionally from the extremities to the trunk and head. They are usually accompanied with considerable itching. Children from six months to four years of age are most liable to this eruption: but adults are not unfrequently affected with it.

iii. *Ecthy*ma.—The ecthy^ma ($\theta\upsilon\omega$, to fume) is an eruption of the inflamed pustules, termed phlyzacia. They are usually distinct, arising at a distance from each other, seldom very numerous, unaccompanied by fever, and not contagious.

1. Ecthy^ma luridum.

2. Ecthy^ma vulgare.

3. Ecthy^ma infantile.

4. Ecthy^ma cachecticum.

iv. *Scabies*.—The scabies, or itch, is an eruption of pustules, or of small vesicles, which are subsequently intermixed with, or terminate in, pustules; it is accompanied by constant and importunate itching, but not with fever; and is in all its varieties contagious. It appears occasionally on every part of the body, the face only excepted; but most abundantly about the wrists and fingers, the fossa of the nates, and the flexures of the joints.

1. The scabies papuliformis, or rank itch, consists of an extensive eruption of minute itching vesicles, which are slightly inflamed and acuminated, resembling papulæ when examined by the naked eye. They commonly arise first about the bend of the wrist and between the fingers, or in the epigastrium; on which parts, as well as about the axillæ and nates, and in the flexures of the upper and lower limbs, they are at all periods most numerous, and often intermixed with a few phlyzacious pustules containing a thick yellow matter.

2. The scabies lymphatica, or watery itch, is distinguished by an eruption of transparent vesicles, of a considerable size, and without any inflammation at their base. They arise in succession, with intense itching, chiefly round the wrists, between the fingers, on the back of the hands, and on the feet and toes: they often occur also about the axillæ, the hams, the bend of the elbows, and fossa of the nates, where they are intermixed with pustules: but they do not frequently appear, like the papuliform species, over the breast and epigastrium, nor on the thighs and upper parts of the arms.

3. The scabies purulenta, or pocky itch, is, I believe, often mistaken by those who confine their notion of the disease to the ordinary small and ichorous vesicle of the two former species. The eruption consists of distinct, prominent, yellow, pustules, which have a moderate inflammation round their bases, and which mature and break in two or three days, and then ulcerate, with increasing pain and inflammation. These pustules commonly appear first, and attain the largest size, on the hands and feet, especially about the knuckles and roots of the toes, between the fingers, and particularly between the forefinger and thumb, and round the wrists. In these situations the pustules often exceed two lines in diam-

ter, and assume a prominent globular form : whence, from their general resemblance to the large well matured pustules of small pox (and not from any allusion to syphilis, as some have erroneously supposed), the popular term *pocky* has been applied to them.

4. Scabies cachectica. This variety of scabies exhibits, in different parts of the body, all the appearances which belong to the three foregoing species. It is occasionally also combined with patches resembling lichen, psoriasis, or impetigo, especially in adults, or young persons approaching the term of puberty; whence it assumes an ambiguous character.

Order V.—VESICULÆ.

In this order *varicella* and *vaccinia* being generally understood, we shall proceed to

i. *Herpes* (ερω, to creep). This appellation is here limited to a vesicular disease, which, in most of its forms, passes through a regular course of increase, maturation, and decline, and terminates in about ten, twelve, or fourteen days. The vesicles arise in distinct but irregular clusters, which commonly appear in quick succession, and they are set near together, upon an inflamed base, which extends a little way beyond the margin of each cluster.

1. *Herpes phlyctænodes*.—This species of the eruption, including the miliary variety above-mentioned, is commonly preceded by a slight febrile attack for two or three days. The small transparent vesicles then appear in irregular clusters, sometimes containing colorless, and sometimes a brownish, lymph; and, for two or three days more, other clusters successively arise near the former.

2. *Herpes zoster*.—Shingles.

3. *Herpes circinatus*.—This form of the herpes is vulgarly termed a ringworm, and is, in this country, a very slight affection, being unaccompanied with any disorder of the constitution. It appears in small circular patches, in which the vesicles arise only round the circumference: these are small, with moderately red bases, and contain a transparent fluid, which is discharged in three or four days, when little prominent dark scabs form over them. The central area, in each vesicular ring, is at first free from any eruption; but the surface becomes somewhat rough and of a dull red color, and throws off an exfoliation as the vesicular eruption declines, which terminates in about a week with the falling off of the scabs, leaving the cuticle red for a short time.

4. *Herpes labialis*.—A vesicular eruption upon the edge of the upper and under lip.

5. *Herpes præputialis*.—This local variety of herpes was not noticed by Dr. Willan; but it is particularly worthy of attention, because it occurs in a situation where it is liable to occasion a practical mistake of serious consequence to the patient. The resemblance alluded to is that of chancre on the prepuce, which has been already explained when treating of diseases of the penis.

iv. *Rupia*.—The *rupia* (*rumporupi*) is characterised by an appearance of broad and flattish vesicles, in different parts of the body, which do not become confluent: they are slightly inflamed at the base, slow in their progress, and succeeded by an ill-conditioned discharge, which concretes into thin and superficial scabs that are easily

rubbed off and presently regenerated. It appears under some varieties of form which may be included under the following heads:—

1. *Rupia simplex* consists of little vesications, containing, on their first appearance, a clear lymph, and appearing on many parts of the body. In a short time the fluid included in them begins to thicken, and becomes at length opaque and somewhat puriform: a slight ulceration of the skin takes place, with a sanious discharge, followed by scabbing; and when this heals it leaves the surface of a livid or blackish color, as if from a thickening of the rete mucosum.

2. *Rupia prominens* is distinguished by elevated conical scabs, which are gradually formed upon the vesicated bases. A fluted scab is first generated, and with some rapidity (e. g. in the course of the night), as the fluid of the vesication concretes.

v. *Miliaria*.—The *miliaria* (*milium*) is characterised by a scattered eruption of minute round vesicles, about the size of millet seeds, surrounded by a slight inflammation, or rash, and appearing at an uncertain period of febrile disorders. The eruption is immediately preceded by unusual languor and faintness, by profuse perspiration, which often emits a sourish odor, and by a sense of great heat, with a prickling and tingling in the skin. It appears most abundantly upon the neck, breast, and back, sometimes in irregular patches, and sometimes more generally diffused, and remains on those parts during several days: on the face and extremities it is less copious, and appears and disappears several times without any certain order. The vesicles, on their first rising, being extremely small and filled with a perfectly transparent lymph, exhibit the red color of the inflamed surface beneath them; but, in the course of thirty hours, the lymph often acquires a milky opacity, and the vesicles assume necessarily a white or pearly appearance.

vi. *Eczema*.—The *eczema* (ζεω, to boil) is characterised by an eruption of small vesicles on various parts of the skin, usually set close or crowded together, with little or no inflammation round their bases, and unattended by fever. It is not contagious.

This eruption is generally the effect of irritation, whether internally or externally applied, and is occasionally produced by a great variety of irritants in persons whose skin is constitutionally very irritable.

vii. *Aphtha*, thrush. The *aphthæ* (απτω, to kindle), are small, whitish, or pearl-colored vesicles, appearing on the tongue, lips, and the interior surface of the mouth and throat, generally in considerable numbers, proceeding to superficial ulceration, and terminating by an exfoliation of whitish crusts.

Order VII.—TUBERCULÆ.

i. *Phyma*
ii. *Verruca*
iii. *Mollusca* } have been treated of in an earlier part of this article.

iv. *Vitiligo*.—This is an uncommon disease, and defined to be an appearance of smooth white shining tubercles, which gradually subside to the level of the skin, creeping along and chequering the whole superficies with a veal like appearance. Wherever the disease passes all the hairs drop

out, and never sprout again, leaving a smooth polished appearance of the skin during life.

v. *Acne*.—This genus is characterised by an eruption of distinct, hard, inflamed tubercles, which are sometimes permanent for a considerable length of time, and sometimes suppurate very slowly and partially. They usually appear on the face, especially on the forehead, temples, and chin, and sometimes also on the neck, shoulders, and upper part of the breast; but never descend to the lower parts of the trunk, or to the extremities. As the progress of each tubercle is slow, and they appear in succession, they are generally seen at the same time in the various stages of growth and decline; and, in the more violent cases, are intermixed likewise with the marks or vestiges of those which have subsided. The eruption occurs almost exclusively in persons of the sanguine temperament, and in the early part of life, from the age of puberty, to thirty or thirty-five; but, in those of more exquisite temperament, even later. It is common to both sexes; but the most severe forms of it are seen in young men. There are four varieties of this eruption, which may be designated by the titles of *acne simplex*, *punctata*, *indurata*, and *rosacea*.

vi. *Sycosis* (*συκη*, a fig), consists of an eruption of inflamed but not very hard tubercles, occurring on the bearded portion of the face and on the scalp, in adults, and usually clustering together in irregular patches. Celsus has correctly stated that some difference takes place in the appearance and progress of the eruption, when it is seated in the chin, and in the scalp; whence he divides it into two species.

In the *sycosis menti* the tubercles arise first on the under lip, or on the prominent part of the chin, in an irregularly circular cluster; but this is speedily followed by other clusters, and by distinct tubercles, which appear in succession, along the lower part of the cheeks up to the ears, and under the jaw towards the neck, as far as the beard grows. The tubercles are red and smooth, and of a conoidal form, and nearly equal to a pea in magnitude. Many of them continue in this condition for three or four weeks, or even longer, having attained their full size in seven or eight days; but others suppurate very slowly and partially, discharging a small quantity of thick matter, by which the hairs of the beard are matted together, so that shaving becomes impracticable, from the tender and irregular surface of the skin. This condition of the face, rendered rugged by tubercles from both ears round to the point of the chin, together with the partial ulceration, and scabbing, and the matting together of the unshaven beard, occasions a considerable degree of deformity; and it is accompanied also with a very troublesome itching.

vii. *Lupus*, treated like ulceration in general.

viii. *Elephantiasis*.—The elephantiasis, as described by the Greeks, is principally characterised by the appearance of shining tubercles, of different sizes, of a dusky red or livid color, on the face, ears, and extremities; together with a thickened and rugous state of the skin, a diminution or total loss of its sensibility, and a falling off of all the air, except that of the scalp.

But at present by this term we understand to be meant what is vulgarly called Barbadoes' leg, and constitution, a remarkable thickening of the integuments of the legs, unattended with any pain or any appearance of disease. This inconvenient disorder affects the natives of the Society Islands, and even some of the missionaries who have been resident there many years.

ix. *Frambæsia*.—The eruption of the yaws sometimes commences without any precursory symptoms of ill-health; but it is generally preceded by a slight febrile state, with languor, debility, and pains of the joints, resembling those of rheumatism. After several days minute protuberances appear on various parts of the skin, at first smaller than the head of a pin, but gradually enlarging, in some cases to the diameter of a sixpence, and in others even to a greater extent: they are most numerous, and of the largest size, in the face, groins, axillæ, and about the anus and pudenda. But the crop is not completed at once; new eruptions appear in different places, while some of the earlier ones dry off. When the cuticle is broken a foul crust is formed on the surface, from under which, on the larger protuberances, red fungous excrescences often spring up, which attain different magnitudes, from that of a small raspberry to that of a large mulberry, which fruit they somewhat resemble from their granulated surfaces.

Order VIII.—MACULÆ.

i. *Ephelis*, *ἠλιος*, the sun. The term *epheles* denotes not only the freckles, or little yellow lentigines, which appear on persons of fair skin, and the larger brown patches which likewise arise from exposure to the direct rays of the sun, as the name imports; but also those large dusky patches, which are very similar in appearance, but occur on other parts of the surface, which are constantly covered.

ii. *Nævus* comprises various congenital excrescences and discolorations of the skin. These are composed of a tissue of small veins and arteries, which communicate freely with each other, and are apt at times to enlarge even to an alarming extent. The only mode of cure is complete extirpation, as recommended by John Bell in his surgical works.

iii. *Spilus*, moles. These occur in most cases at the time of birth, but have been known to supervene afterwards. It is in general not safe to meddle with them, as we reap no advantage from any kind of treatment, and they seldom occasion any trouble to the individual whom they affect.

We have thus given a brief sketch of the diseases of the skin, preserving the classification of Drs. Willan and Bateman, to which works, not forgetting also the later and more splendid publication of Alibert, we must refer those who wish to render their knowledge of this department more perfect and satisfactory. It must be lamented that more light has not been hitherto thrown on this interesting though obscure class of maladies; but we may confidently anticipate a near approach to the period when this will receive its share of that improvement which is now making such rapid strides in every other department of science.

SURINAM, a colony of Guiana in South America, settled by the Dutch. It is bounded on the north by the Atlantic, on the east by the river Marawina, on the south by a country of Indians, and on the west by the river Corentin; about 150 miles from east to west, and sixty from north to south. The rivers that belong to this settlement are the Surinam (from which the colony takes its name), Corentin, Copename, Seramica, and Marawina. The first only is navigable; the rest, not excepting the Marawina, being, though very long and broad, so shallow and beset with rocks and islands that they are of little consequence. The other branch of this large river is named Commewina, and keeps due east for about sixteen miles, with a depth of about three or four fathoms at high-water mark; but, as the tide makes a difference of twelve feet, it is not considered as navigable for any ships of burden, though its breadth may be computed at about two miles. The banks, though later cultivated than those of the Surinam, are in a more flourishing condition, and considered more healthy. Coffee is mostly planted on the estates which lie on the side of this river; and the plantations have a respectable appearance. At the distance of sixteen miles the Commewina is again divided into two branches, one of which bears the same name to the south-east for above fifty miles, and that of Coticca to the E. S. E. for more than forty miles, when this last takes a meandering course to the S. S. W. Into all these rivers, the courses of which are serpentine, are discharged a number of large creeks or rivulets, the banks of which are inhabited by Europeans, and cultivated with sugar, cocoa, cotton, and indigo; but in some places the woods, &c., are absolutely impenetrable, a small path of communication between Paramaribo and the river Seramica being the only passable road in the settlement. The rivers whose banks are uncultivated, such as the Corentin, Copename, Seramica, and Marawina, afford but little matter for description. It is therefore only necessary to remark that they are generally from two to four miles in breadth, exceedingly shallow and crowded with quicksands, islands, and rocks, which form very beautiful cascades. In the Marawina is frequently found a curious stone or pebble, which is known by the name of the Marawina diamond, and which being polished bears a very near resemblance to that most valuable gem, and is consequently often set in rings, &c. A full description of this coast will be found in our article AMERICA, SOUTH, § 208. Paramaribo is the chief town.

SURLY, *adj.* } Sax. *sur*, sour; Swed. *sur-*
SURLING, *n. s.* } *ley*. Morose; rough; un-
civil; sour; silently or gloomily; angry: a
sour morose fellow.

'Tis like you'll prove a jolly *surlly* groom,
That take it on you at the first so roundly. *Shakespeare.*

That *surlly* spirit melancholy,
Had baked thy blood, and made it heavy thick,
Which else runs tickling up and down the veins,
Making that idiot laughter keep men's eyes,
And strain their cheeks to idle merriment.

Id. King John.

Against the capitol I met a lion,
Who glared upon me, and went *surlly* by,
Without annoying me. *Id.* Julius Cæsar.

These sour *surlings* are to be commended to sieur Gaulard. *Camden.*

Thus pale they meet; their eyes with fury burn;
None greets; for none the greeting will return;
But in dumb *surliness*, each armed with care
His foe protest, as brother of the war. *Dryden*

Repulsed by *surlly* grooms, who wait before
The sleeping tyrant's interdicted door. *Id.*

What if among the courtly tribe
You lose a place, and saved a bribe?
And then in *surlly* mood came here
To fifteen hundred pounds a year,
And fierce against the whigs harangued? *Swift.*

The zephyrs floating loose, the timely rains,
Now softened into joy the *surlly* storms. *Thomson.*

SURMISE, *v. a.* & *n. s.* Fr. *surmise*. To suspect; image imperfectly; to imagine without certain knowledge: the noun substantive corresponding.

Of questions and strifes of words cometh envy,
railings, and evil *surmisings*. *1 Tim.* vi. 4.

They were by law of that proud tyranness,
Provoked with wrath, and envy's false *surmise*,

Condemned to that dungeon merciless,
Where they should live in woe, and die in wretch-
edness. *Spenser.*

Man coveteth what exceedeth the reach of sense,
yea somewhat above capacity of reason, somewhat
divine and heavenly, which with hidden exultation it
rather *surmiseth* than conceiveth. *Hooker.*

To let go private *surmises*, whereby the thing itself
is not made better or worse; if just and allowable
reasons might lead them to do as they did, then are
these censures frustrate. *Id.*

My thought, whose murdering yet is but fantasti-
cal,

Shakes so my single state of man, that function
Is smothered in *surmise*. *Shakespeare. Macbeth.*

No sooner did they espy the English turning from
them, but they were of opinion that they fled towards
their shipping; this *surmise* was occasioned, for that
the English ships removed the day before.

Hayward.

We double honour gain
From his *surmise* proved false. *Milton.*

Surmise not

His presence to these narrow bounds confined. *Id.*

It wafted nearer yet, and then she knew
That what before she but *surmised*, was true.

Dryden.

This change was not wrought by altering the
form or position of the earth, as was *surmised* by
a very learned man, but by dissolving it.

Woodward.

Hence guilty joys, distastes, *surmises*,
False oaths, false tears, deceits, disguises. *Pope.*

No man ought to be charged with principles he
actually disowns, unless his practices contradict his
profession; not upon small *surmises*. *Swift.*

SURMOUNT, *v. a.* Fr. *surmonter*. To rise
above; conquer; overcome; surpass.

The mountains of Olympus, Atho, and Atlas
over-reach and *surmount* all winds and clouds.

Raleigh.

What *surmounts* the reach
of human sense, I shall delineate so,
By likening spiritual to corporeal forms,
As may express them best. *Milton's Paradise Lost.*

He hardly escaped to the Persian court; from
whence, if the love of his country had not *sur-*
mounted its base ingratitude to him, he had many
invitations to return at the head of the Persian fleet;
but he rather chose a voluntary death. *Swift.*

Though no resistance was made, the English had much ado to *surmount* the natural difficulties of the place the greatest part of one day. *Hayward.*

SURMULLET, in ichthyology, a name used both by French and English naturalists for the mullus major, a fish of the cuculus kind, and in the Linnean system the mullus cirris geminis, &c., in many things resembling the mullus barbatus, or ruber, but differing from it in that it is twice as big, being often caught of twelve or fourteen inches in length. Its fins also are yellowish, and have a slight blush of red mixed with that color. Its scales are large, and broad, and thick, and are more firmly joined to the flesh. It has also three or four straight yellow lines running parallel with one another down its sides. It is caught in the Mediterranean and in the British seas, especially on the coast of Cornwall, and is every where esteemed a very delicate fish. Pennant calls this species of mullus the striped surmullet; but he expresses a doubt whether this is not a variety, as Gronovius apprehends, of the red surmullet, or mullus barbatus. This last, he observes, was highly esteemed by the Romans, and bore a very high price. They presented it alive to their guests in a glass vessel that they might observe the beautiful changes of its evanescent colors during its expiration. Plin. l. ix. c. 17. See Hor. Sat. lib. ii. § 2. 33., and Juvenal, sat. iv. See **MULLUS**.

SURNAME, *n. s. & v. u. Fr. surnom.* The name of a family; name which one has over and above what is called the Christian name. See below. The verb active corresponding.

Another shall subscribe with his hand unto the Lord, and *surname* himself by the name of Israel.

Isaiah xlv. 5.

Many which were mere English joined with the Irish against the king, taking on them Irish habits and customs, which could never since be clean wiped away; of which sort be most of the *surnames* that end in *an*, as Hernan, Shinan, and Mungan, which now account themselves natural Irish. *Spenser.*

He, made heir not only of his brother's kingdom, but of his virtues and haughty thoughts, and of the *surname* also of Barbarossa, began to aspire to the empire. *Knolles's History.*

Witness may

My *surname* Coriolanus: the painful service,
The extreme dangers, and the drops of blood
Shed for my thankless country, are requited

But with that *surname.* *Shakspeare. Coriolanus.*

Pyreicus, only famous for counterfeiting earthen pitchers, a scullery, rogues together by the ears, was *surnamed* Rupographus. *Peacham on Drawing.*

How he, *surnamed* of Africa, dismissed
In his prime youth the fair Iberian maid. *Milton.*

God commanded man what was good; but the devil *surnamed* it evil, and thereby baffled the command. *South.*

The epithets of great men, monsieur Boileau is of opinion, were in the nature of *surnames*, and repeated as such. *Pope.*

SURNAME is that which is added to the proper name for distinguishing persons and families. It was originally distinguished from surname, which denotes the name of the sire or progenitor; thus Macdonald and Robertson are surnames expressing the son of Donald, the son of Robert. The word surname, again from Fr. sur, above or upon, and nom, name, signified some name

superadded to the proper name to distinguish the individual, as Artaxerxes Longimanus, Harold Harefoot, Malcolm Canmore. From this it is evident that every surname was a surname, but every surname was not a surname. In modern times they are nearly confounded; and, as there is now little occasion to preserve the distinction, Dr. Johnson has rejected the word surname altogether; in which he certainly was premature, for he has retained words much more obsolete. See **NAME**. Surnames have been introduced among most nations, but among many not at a very early period. They seem to have been formed at first by adding the name of the father to that of the son. Among the Hebrews Caleb is denominated the son of Jephunneh, and Joshua the son of Nun. But it is evident that these were not used as surnames. Even so late as our Saviour's time the Jews had no regular family surnames. Some had personal epithets from accidental or characteristical circumstances, as Simon Peter, Judas Lebbaeus, Joseph Barsabas Justus, Judas Iscariot, &c. But none of these were hereditary, as all surnames properly are. Iscariot is thought by some commentators to have been a name taken by Judas from his landed property. We admit that in all nations, while men had but one name, it was usual to distinguish them by mentioning the name of their fathers. That the ancient Greeks as well as the Jews did so is evident from the very first line of the Iliad: *Ἀχιλλῆος Πηληϊάδης*, Achilles the son of Peleus. This perhaps gave rise to surnames, which at last became common among most nations. The old Normans used Fitz, which signifies son; as Fitzherbert, Fitzsimmons, the son of Herbert, the son of Simon. The Irish used O, or Oy, for grandson, which is still used in many parts of Scotland; the compiler's maternal great-grandmother boasted that she had 100 oyes: O'Neal, O'Donnel, &c., therefore signify the grandson of Neal and of Donald. The Scottish Highlanders employed Mac; as Macdonald, the son of Donald. The Saxons added the word son to the end of the father's name, as Williamson. The Romans generally had three names, often four or five. The first, called prænomen, answered to our Christian name, and was intended to distinguish the individuals of the family; the second, called nomen, corresponded to the word clan in Scotland, and was given to all those who were sprung from the same stock; the third, called cognomen, expressed the particular branch of the tribe or clan from which an individual was sprung. Thus Publius Cornelius Scipio: Publius corresponded to our names John, Robert, and William: Cornelius was the name of the clan or tribe, as Campbell was formerly the name of all the duke of Argyll's clients, and Douglas of the retainers of the duke of Hamilton's progenitors: Scipio being added conveyed this information, that Publius, who was of the tribe of the Corneli, was of the family of that Scipio who led about his aged blind father, and became a scipio or staff to him. But they had also the Agnomen, which was generally personal, though sometimes hereditary; and was derived from some particular circumstance or accident happening to individuals. See **AGNO-**

MEN and COGNOMEN. Du Chesne observes that surnames were unknown in France before 987, when the lords began to assume the names of their demesnes. Camden relates that they were first taken up in England a little before the conquest, under king Edward the Confessor; but he adds that they were never fully established among the common people till the time of Edward II. Till then they were varied with the father's name: if the father, e. g., was called Richard or Roger, the son was called Richard-son or Hodgson; but from that time they were settled, some say, by act of parliament. The oldest surnames are those we find in Domesday-book, most of them taken from places, with the addition of *de*; as Godefridus de Mannevilla, Walterus de Vernon, Robert de Olyly, &c. Others from their fathers, with *filius*; as Gulielmus filius Osberni: others from their offices; as Eudo Dapifer, Gulielmus Camerarius, Gislebertus Cocus, &c. But the inferior people are noted simply by their Christian names, without any surnames. Some think they were first introduced into Scotland in the time of William the Conqueror by the English, who accompanied Edgar Atheling when he fled into that kingdom. These had their proper surnames, as Moubray, Lovell, Lisle, &c., using the particle *de* before them; which makes it probable that these surnames had been derived from the lands which their ancestors or they themselves had possessed. But Scottish historians mention some surnames in Scotland at much earlier periods; and trace the surname of Macalpine from a natural son of king Alpine, and that of Macgregor from another bastard of king Gregory the Great, who both reigned in the ninth century. See SCOTLAND. Some antiquaries date the origin of the surname of Graham so early as the fifth century from one Graham, a Scottish hero, who leaped over and demolished part of Antoninus's wall, thence called Graham's Dyke. And it is certain that in Kenneth II.'s time, in 800, the great men had begun to call their lands by their own names; and soon after the various branches of their families took their surnames from these estates. Others, as surnames increased, took their names from their offices, as Stewart; from their business, as Smith, Taylor, &c.; others from their complexion or stature, as Black, White, Red, Brown, Long, Short, &c. It was long before any surnames were used in Wales, except that of son; as Evan ap Rice, Evan the son of Rice; David ap Howel, David the son of Howel: but many of them have at length formed separate surnames, as the English and Scots by leaving out the *a* in *ap*, and joining the *p* to the father's name: thus Evan ap Rice becomes Evan Price; Griffin ap Howel, Griffin Powel.

We are told surnames were unknown in Sweden till 1314, and that the common people of that country use none to this day, and that the same is the case with the vulgar Irish, Poles, and Bohemians. Many surnames were doubtless originally bestowed on account of the qualities of mind, as Bold, Hardy, Meek; some for the qualities of body, as Strong, Low, Short, &c. But the greatest number of surnames were borrowed from the names of places, and not a few from the

country at large; as Scott, Scotland, English, Inglis, England, Wales, Welsh, Ireland, &c. Camden says that there is not a village in Normandy but has given its name to some family in England. He mentions as examples Percy, Devereux, Tankerville, Mortimer, Warren, &c. They were introduced with William I. Several have been derived from places in the Netherlands, as Gaunt, Tournay, Grandison; and many from the names of towns and villages in England and Scotland, as Wentworth, Markham, Murray, Aberdeen. Many have been formed from the names of animals, as Lion, Dog, Hog, Cock, Salmon, &c.; many from vegetables and minerals, &c. Others are formed from such a variety of accidents that it would be trifling to particularise them. After the revival of learning, when most European authors wrote in Latin, it was a very general practice to Latinize their surnames, either by adding a Latin termination to them, or by a complete translation, which often disguised them entirely. Thus Francis Holyoak, author of a Latin dictionary, called himself Franciscus de Sacra Quercu; Kirkwood and Ruddiman, in their Latin grammars, called themselves Kirkwodus and Ruddimannus; and even so late as the end of last century Dr. Brown, in his *Elementa Medicinæ*, styled himself Joannes Bruno; whence the epithet Brunonian was applied to his doctrine and his followers. But surnames ought never to be translated; and Christian names always ought, except when borrowed from surnames. See LOUIS.

SURPASS', *v. a.* Fr. *surpasser*. To excel; to exceed; to go beyond in excellence.

The climate's delicate,
Fertile the isle, the temple much surpassing
The common praise it bears.

Shakespeare. Winter's Tale.

O, by what name, for thou above all these,
Above mankind, or aught than mankind higher,
*Surpass*est far my naming! how may I
Adore thee, author of this universe? *Milton.*

O thou! that, with surpassing glory crowned,
Lookest from thy sole dominion like the god
Of this new world. *Id. Paradise Lost.*

Achilles, Homer's hero, in strength and courage surpassed the rest of the Grecian army. *Dryden.*

His miracles proved him to be sent from God, not more by that infinite power that was seen in them, than by that surpassing goodness they demonstrated to the world. *Culamy.*

Under or near the line are mountains which, for bigness and number, surpass those of colder countries, as much as the heat there surpasses that of those countries. *Woodward.*

SURPLICE, *n. s.* Fr. *surpelis*, *surplis*; Lat. *superpellicium*. The white garb which the clergy wear in their acts of ministration.

It will wear the surplice of humility over the black gown of a big heart.

Shakespeare. All's Well that Ends Well.

The cinctus gabinus is a long garment, not unlike a surplice, which would have trailed on the ground, had it hung loose, and was therefore gathered about the middle with a girdle. *Addison.*

SURPLICE. By Can. 58 every minister saying the public prayers, or ministering the sacrament or other rites of the church, shall wear a decent and comely surplice with sleeves, to be provided at the charge of the parish. But by 1 Eliz. c. 2

and 13 and 14 Car. II., the garb prescribed by act of parliament, in the second year of king Edward VI., is enjoined; and this requires that in the saying or singing of matins, and even songs, baptizing and burying, the minister in parish churches and chapels shall use a surplice. And, in all cathedral churches and colleges, the archdeacon, dean, provosts, masters, prebendaries, and fellows being graduates, may use in the choir, besides their surplices, such hoods as pertain to their several degrees. But in all other places every minister shall be at liberty to use a surplice or not. For the holy communion the rubric appoints a white alb plain, which differs from the surplice in being close-sleeved, with a vestment or cope. See ALB.

SURPLUS, *n. s.* } Fr. *sur* and *plus*. A surplus. } **SURPLUSAGE**. } pernumery part; overplus; what remains when use is satisfied.

If then thee list my offered grace to use,
Take what you please of all this *surplusage*;
If thee list not, leave have thou to refuse. *Spenser*.
That you have vouchsafed my poor house to visit,
It is a *surplus* of your grace. *Shakspeare*.
The officers spent all, so as there was no *surplusage*
of treasure; and yet that all was not sufficient. *Davies*.

When the price of corn falleth, men give over *surplus* tillage, and break no more ground.

We made a substance so disposed to fluidity, that by so small an agitation as only the *surplusage* of that which the ambient air is wont to have about the middle even of a winter's day, above what it hath in the first part. *Boyle*.

Whatsoever degrees of assent one affords a proposition beyond the degrees of evidence, it is plain all that *surplusage* of assurance is owing not to the love of truth. *Locke*.

SURPRISAL, *n. s.* } Fr. *surprise*. From the }
SURPRISE. } verb. The act of taking }
unawares; the state of being taken unawares: a }
dish, explained in the extract.

The castle of Macduff I will *surprise*,
Seize upon Fife, give to the edge o' the sword
His wife, his babes. *Shakspeare. Macbeth*.
I set aside the taking of St. Jago and St. Domingo,
in Hispaniola, as *surprizes* rather than encounters. *Bacon*.

Now do our ears before our eyes,
Like men in mists,
Discover who'd the state *surprize*,
And who resists. *Ben Jonson*.
Parents should mark heedfully the witty excuses
of their children, especially at sudden *surprisals*;
but rather mark than pamper them. *Wotton*.

This let him know,
Lest willfully transgressing, he pretend
Surprisal, unadmonished, unforewarned.
Milton's Paradise Lost.
Up he starts, discovered and *surprised*. *Milton*.
The people were not so much frightened as *surprized* at
the bigness of the camel. *L'Estrange*.

This strange *surprisal* put the knight
And wrathful squire into a fright. *Hudibras*.
He whose thoughts are employed in the weighty
cares of empire is not presumed to inspect minuter
things so carefully as private persons; the laws there-
fore relieve him against the *surprizes* and machinations
of deceitful men. *Davenant*.

There is a vast difference between them, as vast as
between inadvertency and deliberation, between *sur-
prize* and set purpose. *South*.

The greatest actions of a celebrated person, how-
ever *surprising* and extraordinary, are no more than
what are expected from him. *Addison. Spectator*.

If out of these ten thousand we should take the
men that are employed in public business, the num-
ber of those who remain will be *surprisingly* little. *Addison*.

Few care for carving trifles in disguise,
Or that fantastick dish some call *surprise*.
King's Cookery.

How shall he keep, what, sleeping or awake,
A weaker may *surprise*, a stronger take? *Pope*.
Who can speak

The mingled passions that *surprized* his heart?
Thomson.

SURQUEDRY, *n. s.* Old Fr. *sur* and *cuider*,
to think. Overweening; pride; insolence. Ob-
solete.

They overcommon were deprived
Of their proud beauty, and the one moiety
Transformed to fish for their bold *surquedry*.
Spenser.

Late-born modesty
Hath got such root in easy waxen hearts,
That men may not themselves their own good parts
Extol, without suspect of *surquedry*. *Donne*.

SURRENDER, *v. a., v. n.* } Old Fr. *sur-*
SURREND'RY, *n. s.* [& *n. s.* } *rendre*. To yield }
up; deliver up: yield; give one's self up: the }
act of yielding or resigning.

Solemn dedication of churches serves not only to
make them public, but further also to *surrender* up
that right which otherwise their founders might have
in them, and to make God himself their owner. *Hooker*.

He, willing to *surrender* up the castle, forbade his
soldiers to have any talk with the enemy. *Knolles*.
If our father carry authority with such disposition
as he bears, this last *surrender* of his will but offend
us. *Shakspeare*.

Ripe age bade him *surrender* late,
His life and long good fortune unto final fate.
Fairfax.

As oppressed states made themselves homages to
the Romans to engage their protection, so we should
have made an entire *surrendry* of ourselves to God,
that we might have gained a title to his deliverances.
Decay of Piety.

That hope quickly vanished upon the undoubted
intelligence of that *surrender*. *Clarendon*.

Our general mother, with eyes
Of conjugal attraction unrepoved,
And meek *surrender*, half-embracing lean'd
On our first father. *Milton's Paradise Lost*.
This mighty Archimedes too *surrenders* now. *Glanville*.

Recal those grants, and we are ready to *surrender*
ours, resume all or none. *Davenant*.

In passing a thing away, by deed of gift, is re-
quired a *surrender* on the giver's part of all the
property he has in it; and, to the making of a thing
sacred, this *surrender* by its right owner is necessary.
South.

Juba's *surrender*
Would give up Africk unto Caesar's hands.
Addison.

Having mustered up all the forces he could, the
clouds above and the deeps below, he prepares for a
surrender; asserting, from a mistaken computation,
that all these will not come up to near the quantity
requisite. *Woodward*.

Surrender up to me thy captive breath;
My power is nature's power, my name is Death.
Harte

SURRENDER, in common law, is a deed or instrument, testifying that the particular tenant of lands and tenements, for life or years, doth sufficiently consent and agree, that he who has the next or immediate remainder or reversion thereof shall have the present estate of the same in possession; and that he hereby yields and gives up the same to him, so that the estate for life or years may merge or drown by mutual agreement of the parties. Of surrenders there are three kinds; a surrender properly taken at common law; a surrender of copyhold or customary estates; and a surrender improperly taken, as of a deed, a patent, &c. The first is the usual surrender, and it is usually divided into that in deed and that in law.

SURRENDER, in deed, is that which is really made by express words in writing, where the words of the lessee to the lessor prove a sufficient assent to surrender his estate back again.

SURRENDER, in law, is that wrought by operation of the law, and which is not actual. As if a man have a lease of a farm for life or years, and during the term he accepts a new lease; this act is, in law, a surrender of the former.

SURRENDER of a bankrupt. See **BANKRUPTCY**.

SURRENDER OF COPYHOLDS is the yielding up of the estate by the tenant into the hands of the lord, for such purposes as are expressed in the surrender: as to the use and behoof of A and his heirs, to the use of his own will, and the like. This method of conveyance is so essential to the nature of a copyhold estate that it cannot possibly be transferred by any other assurance. No feoffment, fine, or recovery (in the king's courts) hath any operation upon it. If I would exchange a copyhold with another, I cannot do it by an ordinary deed of exchange at the common law, but we must surrender to each other's use, and the lord will admit us accordingly. If I would devise a copyhold, I must surrender it to the use of my last will and testament; and in my will I must declare my intentions, and name a devisee, who will then be entitled to admission.

SURRENDER OF LETTERS PATENT AND OFFICES. A surrender may be made by letters patent to the king, so that he may grant the estate to whom he pleases, &c.; and a second patent for years to the same person for the same thing is a surrender in law of the first patent.—10 Rep. 66. If an officer for life accepts of another grant of the same office, it is in law a surrender of the first grant; but if such an officer takes another grant of the same office to himself and another, it may be otherwise.

SURREPTION, *n. s.* Lat. *surreptus*. Sudden and unperceived invasion or intrusion.

Sins compatible with a regenerate estate are sins of a sudden *surreption*. *Hammond.*

SURREPTITIOUS, *adj.* } Lat. *surreptitiosus*.

SURREPTIVOUSLY, *adv.* } Done by stealth: gotten or produced fraudulently.

Scaliger hath not translated the first; perhaps supposing it *surreptitious*, or unworthy so great an assertion. *Broune.*

The Masorites numbered not only the sections and lines, but even the words and letters of the Old Testament, the better to secure it from *surreptitious* practices. *Government of the Tongue.*

Thou hast got it more *surreptitiously* than he did, and with less effect. *Id.*

A correct copy of the Dunciad, the many *surreptitious* ones have rendered necessary.

Letter to Publisher of Pope's Dunciad.

SURREY, an inland county of England, in the southern part of the kingdom, is bounded by Sussex on the south, by Kent on the east, by Berkshire and Hampshire on the west, and on the north is separated from Middlesex and a small part of Buckinghamshire by the river Thames. This ranks below most of the other counties of England in extent; its greatest width from north to south being about twenty-six miles, and its utmost length from east to west about thirty-eight. The best authorities compute its contents at 811 square miles, or 519,000 acres.

The *surface* consists of a gentle diversity of hill and dale, the hills in some parts rising to a considerable height, and the whole presenting as great a variety of scenery as any portion of the kingdom. In some parts naked heaths impart a wildness to the prospect, strikingly contrasted with the numberless beauties occasionally scattered over the surface by the hand of art; while the hills, aspiring to the bold character and picturesque scenery of mountains, gradually decline into richly wooded dales, and highly cultivated plains. Its extensive downs also afford extensive pastures. Across the middle of the county, the downs rise with a gentle slope from the north, and are broken in their eastern division into deep and waving valleys. Towards the northern border there are several hills, which afford an extensive view. To the south of the downs, the surface of the county above rises into hills that overhang the Weald. As we approach the Western extremity, these hills cover a greater breadth; and near Womersley, Godalming, and Peperharrow, are covered with a rich foliage, and wave with a graceful line, into intermediate valleys, watered by the different branches of the Wey. On Leith Hill, to the south-west of Dorking, Tilbuster Hill near Godstone, and Gratewood Hill near Godalming, the views are very extensive.

Of the *soil* of this county the different species are much intermixed. They may be reduced to the general heads of clay, loam, and chalk. The most extensive and uniform tract is that which occupies the whole southern border, and forms what is denominated the Weald of Surrey; a district about thirty miles in length, and from three to five in breadth. This consists of a cold, retentive clay, upon a subsoil of the same nature; its surface flat, covered with wood, and its elevation less perhaps than any other vale district in the island. Proceeding northwards, the soil is loam, across the whole county. Near Godalming it runs to a great depth, and rests on a base of sandstone, veined with iron ore. Here commences the most remarkable district of the chalky downs, which lie nearly in the middle of the county, entering from Kent, into Surrey, by Croydon and Limpsfield, where their width is about seven miles. They, however, gradually decrease towards the west. Along the summit of the downs, particularly about Walton and Hedley, and between the Mole and the Wey, is a

large extent of heath, which for a considerable depth separates the chalk of the northern from the southern compartment of downs. From the eastern extremity of the downs, running northward, is a variety of soils, consisting chiefly of strong clay and sandy loam, with patches of gravel, reaching almost to Dulwich, from which place to the extremity of the county, near Rotherhithe, is a strong clay.

It is the general opinion that less rain falls in Surrey than in the metropolis; so that the climate may, upon the whole, be regarded as dry, as far as respects the quantity of rain; but the southern border and the low parts near the Thames are damp, from the nature of the soil, the flatness of the surface, and the immense number of trees which cover it. On the other hand, the atmosphere of the chalk hills, which run across the whole county from east to west, is dry, keen, and bracing. On the heaths about Bagshot, Aldershot, and Hind-head, a similar climate prevails. The spring is in general early, and vegetation is not so often checked by frosty mornings, and cold, raw, easterly winds, as in some of the more southern counties. The summers are commonly dry and warm, and the harvest generally commences in the first ten days of August. The wind blows most frequently from the west and south-west, seldom keeping long in any point between the north-west and north-east: but in the spring, and frequently towards the end of autumn, easterly winds prevail; and the weather is then cold and raw; but the greatest quantity of rain falls when the wind blows from the S. S. W. or south.

Iron ore is found in considerable quantities in the south-west part of Surrey, about Haslemere, Dunsfold, and Cranley; and in the south-east quarter, about Lingfield and Horne; but in consequence of the high price of fuel the works have been neglected. Fuller's earth is found both to the north and south of the downs, but the former is of inferior quality. Extensive quarries of stone are worked near Godstone and its vicinity. When first taken from the quarry it is incapable of bearing a damp atmosphere; but after being kept covered for a few months it becomes sufficiently firm to resist the heat of a common fire, and is called fire-stone. In consequence of this property it is much in demand for fire-places. The stones are of various sizes, from ten inches thickness to seventy-two superficial feet. There are large quarries of limestone near Dorking, particularly serviceable in the construction of works under water. Chalk is abundant and in general use as a manure. The sand is in great request for hour-glasses; and the brick-earth produces excellent fire-bricks.

The principal rivers are the Wey, Mole, and Wandle; the Thames also washes the northern border of this county. The former, after watering the county in different directions, finally discharge themselves into the Thames. A considerable branch of the Medway rises in the parishes of Godstone and Horne, and passing through Lingfield quits Surrey and enters Kent. The Loddon also skirts Surrey on its west side, and is used for the supply of the Basingstoke canal. In the western and south-eastern parts of the

county are ponds, preserved as stew-ponds, to keep fish to supply the London market. The mineral waters of Surrey were at one period in high repute, but are now wholly neglected. This county is in general well furnished with springs.

As to *agricultural* improvement, the drill husbandry has not found many followers, except in the west part of the county, in some parts of which it is general. The produce of wheat is from two to five, and sometimes six quarters an acre, and that of barley, which is here a fine crop, from four to seven and a half. The climate of Surrey seems to be less favorable to oats, the produce of which is sometimes very low, not exceeding three quarters per acre. Garden peas and beans are cultivated in the neighbourhood of the metropolis, and the sandy loams near the Thames, about Mortlake; while the field varieties of both are extensively grown in most other parts, and especially on the chalk hills. Turnips are raised in large crops; and hops are largely cultivated about Farnham. Carrots, clover, sainfoin, and hops, are also extensively cultivated; and a greater quantity of land is employed in raising physical herbs, we are told, than in any other county in Britain. Those which are chiefly reared are peppermint, lavender, camomile, aniseed, liquorice, and poppy. The whole quantity of garden ground employed for the London market in this county amounts to about 3500 acres. Surrey is not celebrated for any particular breed of cattle. The Holderness, or short-horned breed of cows, is preferred; and the rearing of calves for the metropolis was once a common employment, but is now almost disused. The cattle chiefly bred are sheep, oxen, and hogs; many geese are also kept. Within the last ten years large tracts of the heath-lands have been enclosed and cultivated; before which period it was calculated that nearly one-sixth part of Surrey was in a very unprofitable state: the whole amount of waste lands is still computed at 70,000 acres. This county contains the Basingstoke canal, which runs from that place to the Wey; the Wey and Arun junction canal, which falls into the Wey about a mile above Guildford, thus opening a direct communication with the sea; the Surrey, which communicates with the Thames at Rotherhithe; and the Croydon, which commences there and enters the Surrey canal at Deptford. On the Wey the first locks used in England were erected.

According to the Roman division of England, Surrey formed a part of the province of *Britannia Prima*. At the Saxon heptarchy it constituted, with Sussex, a distinct state, under the title of *Suth-Seaxna-ric*; and on the division into shires, this district, from its southern situation, was called *Suthrea*, since modulated to Surrey. On the Danish invasion, and the Norman conquest, the landed property was divided and given to the followers of the victorious monarchs. In later times the history of Surrey is trivial. During the civil wars it adhered to the parliament, and petitioned them for the removal of the 'evil counsellors' who were around the king. As early as the time of the Saxons it conferred the title of earl; and Huda, the first who bore that distinction, was slain, in 853, in battle with

the Danes. Surrey is divided into thirteen hundreds, which contain one county town, four-teen boroughs and market towns, and 140 parishes, all in the diocese of Winchester, with the exception of nine parishes peculiar to the see of Canterbury. It is represented in parliament by eleven members, four for the county, and two for each of the boroughs of Southwark, Guildford, and Lambeth, and one for Reigate.

SURROGATE, *SURROGATUS*, a person substituted or appointed in room of another; most commonly of a bishop, or bishop's chancellor.

SURROUND, *v. a.* Fr. *surronder*. To environ; encompass; enclose on all sides.

Cloud and ever-during dark
Surrounds me, from the cheerful ways of men
Cut off.

As the bodies that surround us diversely effect our organs, the mind is forced to receive the impressions.

SURSOLID, *n. s.* In algebra. The fourth multiplication or power of any number whatever taken as the root. A sursolid problem is that which cannot be resolved but by curves of a higher nature than a conic section.

SURTOUT, *n. s.* Fr. *surtout*. A large coat worn over all the rest.

The *surtout*, if abroad you wear,
Repels the rigor of the air;
Would you be warmer, if at home
You had the fabrick, and the loom?

Sir Roger she mortally hated, and used to hire fellows to squirt kennel-water upon him, so that he was forced to wear a *surtout* of oiled cloth, by which means he came home pretty clean, except where the *surtout* was a little scanty.

SURVENE, *v. a.* Fr. *survenir*. To supervene; to come as an addition.

Hippocrates mentions a supuration that *survenes* lethargies, which commonly terminates in a consumption.

SURVEY, *v. a. & n. s.* } Old Fr. *surveoir*.
SURVEYOR, *n. s.* } To overlook; have under the view; examine: a view; prospect; superintendence: a surveyor is an overseer; one placed to superintend; a measurer of land.

The husbandmen's self came that way,
Of custom to survey his ground.

Should we survey
The plot of situation, and the model;
Question surveyors, know our own estate,
How able such a work to undergo,
To weigh against his opposite.

Wer't not madness, then
To make the fox surveyor of the fold?

Bishop Fox was not only a grave counsellor for war or peace, but also a good surveyor of works.

Though with those streams he no resemblance hold,
Whose form is amber, and their gravel gold;

His genuine and less guilty wealth t' explore,
Search not his bottom, but survey his shore.

Under his proud survey the city lies,
And like a mist beneath a hill doth rise.

Her stars in all their vast survey
Useless besides!

With altered looks,
All pale and speechless, he surveyed me round.

Early abroad he did the world survey
As if he knew he had not long to stay.

SURVEYING OF LAND is the art of measuring, planning, and computing the contents of fields and estates. In England the unit of land measure is the acre, which contains 4840 square yards; and it is subdivided into roods and perches, or poles; four roods making an acre, and forty perches a rood.

Land is measured with a chain, called Gunter's chain, from its inventor. It is twenty-two yards long, and is divided into 100 equal links, each 7·92 in length. An acre therefore contains 100,000 square links.

The lines measured, for ascertaining the dimensions and determining the contents of fields, are generally set down, and their contents computed in links; and, five figures on the right of the contents in links being pointed off for decimals, the figures on the left are acres, and the decimals being reduced to roods and perches, the content is exhibited in the usual denominations of acres, roods, and perches.

In measuring distances with a chain, provide ten small arrows, and give them to the person who is to lead the chain, and, holding one end of the chain in your left hand at the point at which you are to begin to measure, let the leader go forward in the required direction, holding the other end of the chain and one of the arrows in his right hand; you pointing with your right hand to the right or the left, according to the direction in which you wish him to move. When he is exactly in a line with the object which you wish to measure to, point towards the ground, to indicate that the leader must there stick an arrow in the ground at the end of the chain. The leader must then move forward another chain length, keeping the follower in a line with the object departed from, and the follower keeping him in a line with the object to be measured to; the leader and follower thus mutually checking each other, and the leader leaving an arrow at the end of each chain, which is taken up by the follower when the leader has pricked in the next. When all the ten arrows are used, they are returned to the leader to use over again, being changed at the end of every ten chains till the line to be measured is finished; and the number of changes shows the number of tens; to which the arrows in the hands of the follower, and the odd links over from the end of the last chain to the end of the line being added, the length of the line in chains and links is obtained. Thus, if there should be six changes of arrows, and the follower should have eight arrows in his hand, and there be twenty-three links over from the last chain to the mark or end of the line, then the line is in length 6823 links.

In measuring a sloping line, a small pocket level is useful to show how many links ought to be deducted from each chain to reduce the line to its horizontal length, to be used in mapping or plotting the figure; for, though the area of the surface with all its undulations is the content which it is required to exhibit in figures for the content, it is only its surface reduced to a horizontal plane that can be represented on a plan.

SURVEYING.

A staff of ten links long, called an offset staff, is useful in measuring short distances from the main lines.

The cross staff too is a very useful and simple instrument for determining the places from which perpendiculars are to be measured from the main or diagonal lines, to the angles of the field or estate. It consists of two pair of sights at right angles to each other, set on a staff, with a sharp point to fix in the ground. In measuring along the line, when nearly opposite a point of which the perpendicular distance is required, the cross staff is fixed up, and turned round till both ends of the line can be seen through one pair of sights; and it is then moved backward and forward along the line, till, while both the ends of the line are seen through one pair of sights, the object whose perpendicular distance is required, is seen through the other pair; and the distance from the cross staff to the object is its perpendicular distance from the line.

In extensive surveys a theodolite is used to measure angles, and from them, conjoined with a measured base, the lengths of the leading lines are computed trigonometrically, and thus the relative positions of the more distant and principal points in the survey are determined.

But, with whatever instruments the survey may be made, a field book must be kept to register all that is necessary for computing the area, and making a plan of the field or estate surveyed.

The following is a specimen of the form commonly used in measuring along AB in fig. 1, Plate SURVEYING.

Example.—Suppose AB = 1084, AC 896, and BC 738 links, the angle B 55° 2', and CD = 605: required the area by each of the three methods?

A. R. P.

By method first, the area = $\frac{1084 \times 605}{2} = 327910$ links = 3 1 4·6

A. R. P.

By the second, the area = $\sqrt{1359 \times 275 \times 463 \times 621} = 327803$ links = 3 1 4·4

A. R. P.

By the third, the area = $\frac{1084 \times 738 \times A \text{ at } \sin. 55^\circ 2'}{2} = 327790$ links = 3 1 4·4.

These calculations will be considerably facilitated by the use of logarithms. Thus the computation by the second method will stand thus:

AB	1084	
AC	896	
BC	738	
	2)2718	
	1359	Log. 3·133219
	275	2·439333
	463	2·665581
	621	2·793092
		2)11·031225
Area	Links	Log. 5·515612
	327803	

Acres	3·27803
	4
Rods	1·11212
	40
Perches	4·42480

Offsets on the left.	A B.	Offsets on the right.
m 38 . .	120	67 Well.
	156	
n 19 . .	170	
	304	59 o
	320	64 p
q 50 . .	330	
r 43 . .	380	
	402	37 s
	422	18 t
	460	
	B	

In small surveys, such as the preceding is a specimen of, a good way of setting down the work is to sketch on a piece of paper a figure resembling that which is to be measured, and writing the dimensions as they are found against or upon the corresponding parts of the figure.

To survey a triangular field, as A B C, fig. 2, measure one of the sides, as A B, and, by means of the cross staff, find at what point the perpendicular C D will meet the ease, and measure that perpendicular. Or measure the three sides of the triangle; or two of its sides and the angle which they include.

Then in the first case the area of the triangle = $\frac{AB \times CD}{2}$; in the second the area =

$\sqrt{S \cdot S - A B \cdot S - B C \cdot S - A C}$, where S = half the sum of the three sides; and in the third case, supposing A B, B C, and the angle B measured, the area = $\frac{A B \cdot B C \cdot \sin. B}{2}$.

To measure a four sided field as A B C D, fig. 3.

First method.—Measure all the sides, and the diagonal, and the figure will then be divided into two triangles, the area of each of which may be computed by the second of the preceding methods.

Second method.—Measure the diagonal A C, and find by means of the cross staff where the perpendiculars D E and B F from the angles D and B meet the diagonal, and measure D E and B F, and the area will be = $\frac{A C \times D E + B F}{2}$.

Third method.—Measure the longest side, fig. 4, as A B, the several distances A E, E F, and F B; and the perpendicular C E and D F; then find the area of each of the parts, A E C, E F D C, and F D B, and their sum will be the area of the whole.

The area of the triangle A E C is = $\frac{A E \times E C}{2}$;

that of the trapezoid C E F D is

$$\frac{EF \times EC + DF}{2}; \text{ and that of the triangle BFD is } \frac{BF \times FD}{2}.$$

In the preceding figure the area is

$$\frac{AC \times DE + BF}{2}$$

Thus if AC = 1284, DE = 326, and BF = 290 links; then the area = $\frac{1284 \times 326 + 290}{2}$

$$= \frac{1284 \times 616}{2} = \frac{790944}{2} = 395472 \text{ links} =$$

A. R. P.

$$3.95472 \text{ acres} = 3 : 3 : 32.7.$$

In the last figure suppose the annexed the field book of the admeasurements:—

Offsets left.	A B.
C 245 .	267
D 289 .	612
	843
	B

Then 612—267 = 345 = EF, and 843—612 = 231 = FB, and $\frac{267 \times 245}{2} = 32707$ links,

the area of A E C; $\frac{345 \times 245 + 289}{2} = 92115$

links, the area of E F D C; and $\frac{231 \times 289}{2} =$

33379 links, the area of B F D.

Hence	32707
	92115
	33379

A. 1.58201

4

R. 2.32804

40

A. R. P.

P. 13.12160, or the area is 1 2 13.1

Any field of which the sides are straight lines may be divided into triangles, the sides of which being measured, the area of each may be computed, according to the second method above given, for finding the area of a triangular. But they may in general be more advantageously surveyed in the following manner, which we shall give in the words of Dr. Hulton:

‘Having set up marks at the corners where necessary of the proposed field ABCDEFG, fig. 5, walk over the ground and consider how it can be best divided into triangles and trapeziums, and measure them separately. Thus the annexed figure is divided into the two trapeziums, ABCD, GDEF, and the triangle G C D. Then in the first trapezium, beginning at A, measure the diagonal AC, and the two perpendiculars G m, B n. Then the base G C and the perpendiculars D q. Lastly, the diagonal D F, and the two perpendiculars p E, and o G. All which measures write against the corresponding parts of a rough figure drawn to resemble the figure to be surveyed, or set them down in any other form you choose.’ Thus

Offsets Left	A C	Offsets Right
	135	130 G
B 180	410	
	550	
	C	
	C G	
D 230	152	
	440	
	G	
	F D	
120	237	
	288	80
	520	
	D	

Or the figure might have been measured by means of a diagonal from BE, and perpendiculars upon it from the angles on each side. Or, supposing the dimensions of the trapezium ABCG taken as above, the remaining part CGFED might have been measured by means of a diagonal from C to F, and perpendicular upon it from D, E, and G.

From the above field book to compute the area of the figure:—Area of A B C G = $\frac{AC \times B n + G m}{2} = 85250$ links; area of

G D C = $\frac{G C \times q D}{2} = 50600$ links; area of

D E F G = $\frac{F D \times G o + E p}{2} = 52000$ links

Then 85250 + 50600 + 52000 = 187850 links, = 1 A. 3 R. 20.5 P.

Many pieces of land may be very well surveyed by measuring any base line, either within or without them, together with the perpendiculars let fall on it from every corner of them. For they are thus divided into several triangles and trapezoids, all of whose parallel sides are perpendicular to the base line; and the sum of these triangles and trapeziums will be equal to the figure proposed, if the base line fall within it, if not the sum of the parts without being taken from the sum of the whole within and without, the remainder will be the area of the figure.

In pieces that are not very large it will be sufficiently exact to find the points in the base line, where the several perpendiculars will fall by means of the cross, or even by estimating by the eye, and measuring thence to the corners for the lengths of the perpendiculars; and it will be generally better when practicable to have the diagonal within the figure, as the measuring over hedges is attended with inconvenience.

The computing of the contents of very irregular fields may often be greatly simplified, by reducing the crooked sides to straight ones upon the plan; an operation which may be easily and accurately enough performed thus:—

‘Stretch a hair over the crooked sides of the figure, so that the small parts cut off by it may be equal to those taken in, an equality which by a little practice may be judged of with great nicety; then mark the ends of the hair with two points, and proceed in the same manner with the other sides till the whole is reduced to

a straight lined figure, of which the content may be found as above.

Thus, in fig. 6, let the dotted lines AB, BC, CD, DA, represent the lines which reduce the curvilinear area to an equivalent rectangular one; then if AC, measured on the scale from which the figure is laid down, be 843 links, and the perpendiculars De and Bf be 424 and 518 respectively, we have the area = $AC \frac{De + Bf}{2} = 3 A. 3 R. 35-28 P.$

On dividing lands.—In the division of commons, after the whole is surveyed and the area cast up, the quantity due to each claimant must be assigned in proportion to the value of his claim; and, if the land be of different qualities, the quantity to be assigned to each claimant will be inversely proportional to the quality of the land assigned to him. Thus if a, b, c, and d represent the claims of A, B, C, and D to a common whose area is x, and a', b', c', and d' represent respectively the value per acre of the land, from which the allotments to A, B, C, and D are respectively to be made; then $\frac{a}{a'} + \frac{b}{b'} + \frac{c}{c'} + \frac{d}{d'} : x$
 $\therefore \frac{a}{a'} : A$'s share; and $\therefore \frac{b}{b'} : B$'s share, &c.

To cut off from a plan a given quantity by a line drawn from any proposed point in the side of it.

Let A, fig. 7, be the proposed point. Draw any line AB, and measure the space ABQ by the method indicated above. Let us suppose that this is found in defect by a quantity a, then erect at B a perpendicular BD, and make $A = \frac{2a}{AB}$, and through D draw DC parallel to AB, and join AC; then ACBQ will be the part required to be cut off.

To divide a triangle into two parts, having a given ratio, m : n. 1st. By a line drawn from one angle of the triangle.—Make AD : AB :: m : m + n (fig. 8), and join CD; then ADC and BDC will be the parts required. Here it is

plain that $AD = \frac{m}{m+n} AB$; and $DB =$

$\frac{n}{m+n} AB$. 2d. By a line parallel to one of

its sides. Let ABC (fig. 9) be the given triangle, to be divided into two parts, in the ratio of m to n, by a line parallel to the base AB. Make CE to EB as m to n; and at E draw the perpendicular ED meeting a semicircle described on CB as a diameter in D. Make CF = CD, and through F draw FG parallel to AB, and FG will divide the triangle in the given ratio. For CB : CE :: m + n : n; but CB : CE :: CB² : CD² :: CB² : CF², whence the triangle ABC : triangle CGE :: m + n :

n. It is obvious that $CF = CB \sqrt{\frac{m}{m+n}}$

and $CG = CA \sqrt{\frac{m}{m+n}}$. 3d. By lines

drawn from a given point in one of the sides.—

Let P, fig. 9, be the given point, D the point which divides the side AB, n the given ratio;

join DP, and through C draw CE parallel to DP, and join PE, which will divide the triangle as required. For ACD : BCD :: m : n. But the triangles PCD and PDE are equal; therefore the triangles APE and ACD are equal; therefore APE : ABCD :: m : m + n.

On geodetic surveying.—The extensive processes usually termed geodetic, or trigonometrical surveying, are usually undertaken either to determine the differences of longitude between two moderately distant and noted meridians, to give greater accuracy to maps, or to determine from the lengths of degrees of the meridian, in different latitudes, the figure of the earth.

As the foundation of the operations, a line of a few miles in length is carefully measured on some plain, so nearly level as to facilitate the determination of an actually horizontal line; and this being done upon such hills and elevated spots as are suitably situated, and visible from each other, signals are placed; and the straight lines joining those points constitute a series of triangles, of which the measured base forms a side of the first. The angles of these triangles are carefully measured by a theodolite, which is carried from one station to another; and in such a series of triangles care is taken that one side is always common to two of them; so that by the principles of trigonometry the lengths of all the sides of the triangles can be determined in terms of the measured base; and the bearing of any one of the sides, with respect to the meridian, being determined, the bearing of any other side may be found by computation. As a check on operations of this kind towards the end of the survey, another base line, called a base of verification, is generally measured, and determined also from the survey as one of the sides of the chain of triangles; and the agreement of the results is a test of the accuracy with which the operations in the survey, have been performed.

In every such series of triangles, when each angle is to be determined by the same instrument, it is desirable that, as nearly as circumstances will admit, they should be equilateral. For, if it were possible to choose the stations in such a manner that each angle should be exactly 60°, half the number of triangles in the series, multiplied by the length of one of the sides, would (as in fig. 10) give the total distance; and then also the sides of the scale or ladder constituting the series of triangles would be parallel to each other, and so also would the diagonal steps marking the progress from one extremity of the survey to another; and the first side might be found by a base crossing it perpendicularly as at H, and the last side verified by such another base as R at the other extremity.

If the earth were a sphere the length of the degrees of the meridian would be every where the same; but if it be an oblate spheroid, the degrees in receding from the equator to the poles would increase in length, and this increase would be proportionate to the square of the sine of the latitude; and the ratio of the earth's axes, as well as their actual lengths, may be ascertained by comparing the lengths of degrees in different latitudes.

Instead however of actually tracing out a me-

meridian on the surface of the earth, a construction is employed which gives the same result. Let $A, B, C, D, E, F, \&c.$, be a series of triangles carried on as nearly as may be in the direction of the meridian; these triangles are spherical or spheroidal triangles, but their curvature being extremely small they are treated as rectilinear triangles, either by reducing them to the chords of the respective terrestrial arcs, or by subtracting from each angle one-third of the excess of the sum of the three angles above two right angles, and working with the remainder and the three sides as the parts of a plain triangle, the proper reduction for the horizon and the level of the sea having been previously made. These computations being made throughout the series, the sides of the successive triangles are contemplated as arcs of the terrestrial spheroid. Suppose we know by observation and computation the inclination of $A C$ to the first portion $A M$ of the measured meridian, and that we find by trigonometry the point M where that curve will act the side $B C$. The points A, B, C , and the line $A M$, will be in the same horizontal plane, but the prolongation $M M'$ of that line will be above the plane of the second horizontal triangle $B C D$. If therefore, without changing the triangle $C M M'$, the line $M M'$ be brought down to coincide with the plane of this second triangle, the point M' will describe a small arc of a circle which may be regarded as a line perpendicular to the plane $B C D$. Hence the operation is reduced to bending down the side $M M'$ in the plane of the meridian, and calculating the distance $A M M'$ to find the position of M' . By bending down thus in imagination one after another, and in points of the meridian, the corresponding horizontal triangles, we obtain by computation the direction and length of the meridian from one extremity of the triangles to the other.

When all the triangles which constitute such a series have been computed, the respective positions of their angular points, with respect to each other, may be determined thus:—

Let the triangles $A B C, B C D, \&c.$, make parts of a chain of triangles of which the sides are arcs of the sphere; and as we know from observation the angle $C A x$ which measures the inclination of $A C$ to the meridian $A x$; then, having found the excess e of the three angles of the triangle $A C c$ ($C e$ being perpendicular to the meridian) above two right angles, deduct a third of E from each angle of the triangle, and by means of the following proportion find $A c$ and $C e$.

$$\sin. \left(90^\circ - \frac{E}{3}\right) : \cos. \left(C A c - \frac{2E}{3}\right) :: A C : A c$$

$$\sin. \left(90^\circ - \frac{E}{3}\right) : \sin. \left(C A c - \frac{1}{3} E\right) :: A C : A c.$$

The azimuth of $A B$ is given at once; for $B A X = C A B - C A X$; and, if the spherical excess proper to the triangle $A B M'$ be computed, we shall have $A M' B = 180^\circ - M' A B - A B M' + E$.

To determine the sides $A M', B M'$, a third of E must be taken from each of the angles of the triangle $A B M'$, and then

$$\sin. \left(180^\circ - M' A B - A B M' + \frac{2}{3} E\right) : \sin. \left(A B M' - \frac{1}{3} E\right) :: A B : A M'.$$

$$\sin. \left(180^\circ - M' A B - A B M' + \frac{2}{3} E\right) : \sin. \left(M' A B - \frac{1}{3} E\right) :: A B : B M'.$$

In each of the right-angled triangles $A b B, M' d D$, are known two angles and the hypotenuse, whence $A b, b B$, and $M' d, d D$, are readily determined; and consequently the distances of B, D , from the meridian and from the perpendicular, are known.

Proceeding in the same manner with the triangle $A C N$, or $M' D N$, to obtain $A N$ and $D N$, the prolongation of $C D$; and then with the triangle $D N F$ to find the side $N F$, and the angles $D N F$ and $D F N$ it will be easy to complete the rectangular co-ordinate of F .

The distance $f F$, and the angles $D E N, N F f$, being thus known, we have by geometry $f F P = 180^\circ - E F D - D F N - N F f$. So that in the right-angled triangle $f F P$ two angles and one side are known, and hence the spherical excess may be computed, and thence the angle $F P f$, and the sides $f P, P P$. Resolving next the right-angled triangle $e E P$ we obtain the position of the point E with respect to the meridian $A X$, and to its perpendicular $A Y$; and thus we may proceed through the whole series.

Such is a concise sketch of the method to be pursued in determining the length of an arc of the meridian comprised between two points A and X ; the corresponding arc of the celestial meridian is found by determining the latitudes of each of the extremities of the meridian measured; or more commonly by finding the difference of the zenith distances of some known fixed star observed at each extremity.

To deduce from angles measured near one of the stations the true angle at the station.—When the centre of the instrument cannot be placed in the vertical line occupied by the axis of the signal, the angles observed must undergo a reduction. Let C , fig. 12, be the centre of the station, P the place of the centre of the instrument, it is required to find $A C B$, supposing them to be known $A P B = P, B P C = p, C P = d, B C = L, A C = R$.

We have here $A I B = P + I A P$; and $A I P = C + C B P$; whence $C = P + I A P - C B P$. But $\sin. C A P = \frac{d \cdot \sin. (P + p)}{R}$;

$$\sin. C B P = \frac{d \cdot \sin. p}{L}, \text{ and, as the angles } C A P, C B P, \text{ are necessarily very small, we may take}$$

$$C - P = \frac{d \cdot \sin. P + p}{R} - \frac{d \cdot \sin. p}{L}; \text{ or, to}$$

have the reduction in seconds, $C - P = \frac{d}{\sin. 1''}$

$$\left(\frac{\sin. \overline{P + p}}{R} - \frac{\sin. p}{L} \right).$$

The space to which we are limited compels us to omit the investigation of many formulæ connected with the interesting and important application of science to practice. The following are a few of the most important of these formulæ:—

To reduce angles measured in a plane inclined to the horizon to the corresponding angles in the horizontal plane.

Let h, h' , represent the altitudes of the objects, C the angle measured on the oblique plane, and

C' the required corresponding one on the horizontal plane; then $\sin. \frac{C'}{2} =$

$$\sqrt{\frac{\sin. C + h + h'}{2} - h' \sin. \frac{C + h + h'}{2} - h' \text{sect. } h' \text{sect. } K'}.$$

rad. 2.

In a spherical triangle knowing two sides and the included angle to determine the angles comprehended by the chords of those two sides.

Let A, B, C, represent the angles of the triangle; A', B', C', the corresponding angles made by the chords; the spherical sides opposite A, B, C, being a, b, c, and the chords α, β, γ .

Then $\cos. A' = \cos. \frac{b}{2} \cdot \cos. \frac{c}{2} \cdot \cos. A + \frac{\beta}{2} + \frac{\gamma}{2}$.

Or $\cos. A' = \cos. \frac{b}{2} \cdot \cos. \frac{c}{2} \cos. A + \sin. \frac{b}{2}$

$\sin. \frac{\epsilon}{2}$.

Given two sides and the included angle of a rectilinear triangle, it is required to find the spherical angle of the two arcs of which these two sides are the chords?

Let β and γ be the chords, A' the angle which they include, and A the required spherical angle. Then

$$\frac{d}{c} = \sqrt{\frac{(M \frac{1}{2} \cdot \sin. L + m \frac{1}{2} \sin. l) \cdot (M \frac{1}{2} \cdot \sin. L - M \frac{1}{2} \cdot \sin. l)}{(m \frac{1}{2} \cdot \cos. l + M \frac{1}{2} \cos. L) \cdot (n \frac{1}{2} \cdot \cos. l - M \frac{1}{2} \cdot \cos. L)}}$$

$\frac{d}{c} - 1 = \frac{d-e}{c}$ is called the compression of the terrestrial spheroid, and it is evidently given when $\frac{d}{c}$ is determined.

Surveying of harbours.—The method of surveying harbours, and forming maps of them, depends on the same principles, and is in general conducted in the same manner as common surveying. A base line if possible is measured on shore, and, signals being erected at the principal points round the harbour, the angles which they make with the base line are determined, and then their position with respect to each other found either by computation or projection. The best instrument for measuring such angles is Hadley's reflecting quadrant or sextant, as it is the only instrument in which neither the exactness of the observation nor the ease with which they may be made is sensibly affected by the motion of the vessel, and in this department of surveying it will often be necessary to measure angles afloat. Let it be proposed to take the necessary measures for making a plan of the harbour C G D, fig. 13.

Select some convenient place, as AB, to measure a base line, and set up signals at C, D, G, &c. At A measure the angle C' A D, and at B measure the angle C B A; then these angles with A B will give the position of C with respect to A B. At B measure the angle C B D, and at C measure the angle B C D; or going to D measure the angle B D C; these measures with C B, determined by the triangle A B C, will give the position of D. At C' and D take the G C' D and G D C', which with C D' already determined will

$$\cos. A = \frac{\cos. A' - \frac{1}{2} \beta \gamma}{\sqrt{1 - \frac{1}{2} \beta \cdot 1 + \frac{1}{2} \beta \cdot 1 - \frac{1}{2} \gamma \cdot 1 + \frac{1}{2} \gamma}}$$

To compute the spherical excess, E:—

Let S=the arc of the triangle, R'=206264.8', the seconds in an arc equal to the radius, and r the radius of the earth; then $E = \frac{R' \cdot S}{r}$. Hence

it may be noted that $S = \frac{b \cdot c \cdot \sin. A}{2}$.

Given a base, B, measured at an elevation, I, above the level of the sea, to find the corresponding base, b, when reduced to the level of the sea!

Let r = the radius of the earth, then

$$B - b, \text{ or the reduction} = B \cdot \left(\frac{h}{r} - \frac{h^2}{r^2} + \frac{h^3}{r^3} - \frac{h^4}{r^4} + \&c. \right)$$

From the measures M and m of a degree, or like small portions of the meridian in different latitudes L and l, to find the ratio of the polar axis c to the equatorial axis d.

give the position of C. Proceed in this manner till the situation of all the principal points are determined, and then either sketch in the intermediate spaces by the eye or lay them down from particular admeasurements. To find the situation of anchoring places, such as E; or rocks or sands such as F; row off to those places in a boat; and when at E measure the angles A E B and B E D, and segments of circles described in A B and B D respectively, to contain those angles will give the position of the point E. Or with a compass take the bearing of any two points as B and D, and the intersection of those lines of bearing will give the position of E, the relative bearing of the principal point on shore being previously determined. Thus may the situation of F, or any other point in the harbour, be determined and inserted in the plan.

SURVIEW', v. a. Old Fr. *surveoir*. To overlook; to have in view; to survey. Not in use

That turret's frame most admirable was,
Like highest heaven compassed round,
And lifted high above this earthly mass,
Which it *surviewed*, as hills do lower ground.

Spenser.

SURVIVE', v. n. & v. a. } Lat. *supervivo*;
SURVIVOR, n. s. } Fr. *survivre*. To
SURVIVORSHIP. } live after the death
of another: survive any person or thing: the noun substantives corresponding.

Now that he is dead, his immortal fame *surviveth*, and flourisheth in the mouths of all people.

Spenser.

Your father lost a father,
That father his; and the *survivor* bound,
In filial obligation, for some term,
To do obsequious sorrow. *Shakespeare Hamlet*.

Try pleasure,
Which, when no other enemy survives,
Still conquers all the conquerors. *Denham.*
I did discern
From his survivors, I could nothing learn. *Id.*

Although some died, the father beholding so many
descents, the number of survivors must still be very
great. *Browne.*

The love of horses which they had alive.
And care of chariots, after death survive. *Dryden.*
Her majesty is heir to the survivor of the late king.
Swift.

No longer now that golden age appears,
When patriarch-wits survived a thousand years,
Now length of fame, our second life, is lost,
And bare threescore is all even that can boast;
Our sons their fathers' failing language see,
And such as Chaucer is, shall Dryden be. *Pope.*

Such offices granted in reversion were void, unless
where the grant has been by survivorship.

Ayliffe's Parergon.
The rapsodies, called the Characteristics, would
never have survived the first edition, if they had not
discovered so strong a tincture of infidelity. *Watts.*

SURVIVORSHIP is that branch of mathematics which treats of reversions payable, provided one or more particular persons survive certain others. By reversions are meant payments not to take place till some future period. Survivorship forms one of the most difficult and complicated parts of the doctrine of reversions and life annuities. It has been very fully treated of by Simpson in his *Select Exercises*; and brought to a state of comparative perfection by Dr. Price and Mr. Morgan, who bestowed a great deal of attention on this subject. See ANNUITIES.

The calculations are founded on the expectation of lives at different ages, deduced from tables formed from bills of mortality, of which see examples under the article MORTALITY. By the expectation of life is meant the mean time that any single or joint lives at a given age is found to continue; that is, the number of years which, taken one with another, they actually enjoy, and may be considered as sure of enjoying; those who survive that period enjoying as much more time in proportion to their number as those who fall short of it enjoy less. Thus, supposing forty-six persons alive all forty years of age, and that one will die every year till they are all dead in forty-six years, half forty-six or twenty-three will be the expectation of each of them. If M. de Moivre's hypothesis were true, that men always decrease in an arithmetical progression, the expectation of a single life is always half its complement, and the expectation of two joint lives one-third of their common complement. By the complement of a life is meant what it wants of eighty-six, which M. de Moivre makes the boundary of human life. Thus if a man be thirty, the complement of his life is fifty-six. Thus, supposing a man forty, his expectation would be twenty-three, the half of forty-six, his complement: the expectation of two joint lives, each forty, would be fifteen years four months, or the third part of forty-six. The number expressing the expectation, multiplied by the number of single or joint lives (of which it is the expectation), added annually to a society, gives the

whole number living together, to which such an annual addition would in time grow. Thus, since nineteen, or the third of fifty-seven, is the expectation of two joint lives, whose common age is twenty-nine, twenty marriages every year between persons of this age would in fifty-seven years grow to twenty times nineteen, or 380 marriages, always existing together. And, since the expectation of a single life is always half its complement, in fifty-seven years twenty single persons added annually to a town will increase to twenty times 28.5, or 570; and when arrived at this number the deaths every year will just equal the accessions, and no farther increase be possible. Hence it appears that the particular proportion that becomes extinct every year, out of the whole number constantly existing together of single or joint lives, must, wherever this number undergoes no variation, be exactly the same with the expectation of those lives, at the time when their existence commenced. Thus was it found that one-nineteenth part of all the marriages among any bodies of men, whose numbers do not vary, are dissolved every year by the deaths of either the husband or wife, it would appear that nineteen was, at the time they were contracted, the expectation of these marriages. In like manner was it found in a society, limited to a fixed number of members, that one twenty-eighth part dies annually out of the whole number of members, it would appear that twenty-eight was their common expectation of life at the time they entered. So likewise, were it found in any town or district, where the number of births and burials are equal, that a twentieth or thirtieth part of the inhabitants die annually, it would appear that twenty or thirty was the expectation of a child just born in that town or district. These expectations, therefore, for all single lives, are easily found by a table of observations, showing the number that die annually at all ages out of a given number alive at those ages; and the general rule for this purpose is to divide the sum of all the living in the table, at the age whose expectation is required, and at all greater ages, by the sum of all that die annually at that age and above it; or, which is the same, by the number (in the table) of the living at that age; and half unity subtracted from the quotient will be the required expectation. Thus, in Dr. Halley's table, the sum of all the living at twenty and upwards is 20724, which, divided by 598, the number living at the age of twenty, and half unity subtracted from the quotient, gives 34.15 for the expectation of twenty. In calculating the value or expectation of joint lives, M. De Moivre fell into various mistakes, which we need not enumerate; as Dr. Price and Mr. Morgan have given tables of the value of lives, not founded on any hypothesis, but deduced from bills of mortality. Mr. Morgan has likewise given rules for calculating values of lives in this manner. Dr. Price, in the third essay of the first volume of his *Treatise on Reversionary Payments*, has also given proper rules for calculating these values, the most important of which are comprehended in the following paragraphs.

I. Suppose a set of married men to enter into

a society in order to provide annuities for their widows, and that it is limited to a certain number of members, and constantly kept up to that number by the admission of new members as the old ones are lost; it is of importance, in the first place, to know the number of annuitants that after some time will come upon the establishment. Now, since every marriage produces either a widow or a widower, and since all marriages taken together would produce as many widows as widowers, were every man and his wife of the same age, and the chance equal which shall die first; it is evident that the number of widows that have ever existed in the world, would in this case be equal to half the number of marriages. And what would take place in the world must also, on the same suppositions, take place in this society. In other words, every other person in such a society leaving a widow, there must arise from it a number of widows equal to half its own number. But this does not determine what number, all living at one and the same time, the society may expect will come to be constantly upon it. It is, therefore, necessary to determine how long the duration of survivorship between persons of equal ages will be, compared with the duration of marriage. And the truth is, that, supposing the probabilities of life to decrease uniformly, the former is equal to the latter; and, consequently, that the number of survivors (or, which is the same, supposing no second marriages), of widows and widowers alive together which will arise from any given set of such marriages constantly kept up, will be equal to the whole number of marriages; or half of them (the number of widows in particular) equal to half the number of marriages. Now it appears that in most towns the decrease in the probabilities of life is in fact nearly uniform. According to the Breslaw Table of Observation, almost the same numbers die every year from twenty years of age to seventy-seven. After this, indeed, fewer die, and the rate of decrease in the probabilities of life is retarded. But this deviation from the hypothesis is inconsiderable; and its effect, in the present case, is to render the duration of survivorship longer than it would otherwise be. According to the London Table of Observations, the numbers dying every year begin to grow less at fifty years of age; and hence to extreme old age there is a constant retardation in the decrease of the probabilities of life. Upon the whole, therefore, it appears that, according to the Breslaw Table, and supposing no widows to marry, the number enquired after is somewhat greater than half the number of the society; but according to the London Table a good deal greater. This, however, has been determined on the supposition that the husbands and wives are of equal ages, and that then there is an equal chance who shall die first. But in reality husbands are generally older than wives, and males have been found to die sooner than females, as appears incontestably from several of the tables in Dr. Prie's Treatise on Reversions. It is therefore more than an equal chance that the husband will die before his wife. This will increase considerably the duration of survivorship on the part of the women, and consequently the

number which we have been enquiring after. The marriage of widows will diminish this number, but not so much as the other causes will increase it. II. If the society comprehends in it from the first all the married people of all ages in any town, or among any class of people where the numbers always continue the same, the whole collective body of members will be at their greatest age at the time of the establishment of the society; and the number of widows left every year will at a medium be always the same. The number of widows will increase continually on the society, till as many die off every year as are added. This will not be till the whole collective body of widows are at their greatest age, or till there are among them the greatest possible number of the oldest widows; and therefore not till there has been time for an accession to the oldest widows from the youngest part. Let us, for the sake of greater precision, divide the whole medium of widows that come on every year into different classes according to their different ages, and suppose some to be left at fifty-six years of age, some at forty-six, some at thirty-six, and some at twenty-six. The widows, constantly in life together, derived from the first class, will come to their greatest age, and to a maximum, in thirty years, supposing, with M. de Moivre, eighty-six to be the utmost extent of life. The same will happen to the second class in forty years, and to the third in fifty years. But the whole body composed of these classes will not come to a maximum till the same happens to the fourth or youngest class; that is, not till the end of sixty years. After this, the affairs of the society will become stationary, and the number of annuitants upon it of all ages will keep always nearly the same. III. If a society begins with its complete number of members, but at the same time admits none above a particular age; if, for instance, it begins with 200 members all under fifty, and afterwards limits itself to this number and keeps it up by admitting every year at all ages between twenty-six and fifty, new members as old ones drop off; in this case, the period necessary to bring the maximum of annuitants will be just doubled. To determine the sum that every individual ought to pay in a single present payment, in order to entitle his widow to a certain annuity for her life, let us suppose the annuity £3 per annum, and the rate of interest four per cent. It is evident that the value of such an expectation is different, according to the different ages of the purchasers, and the proportion of the age of the wife to that of the husband. Let us then suppose that every person in such a society is of the same age with his wife, and that, one with another, all the members when they enter may be reckoned forty years of age, as many entering above this age as below it. It has been demonstrated by M. de Moivre and Mr. Simpson that the value of an annuity on the joint continuance of any two lives, subtracted from the value of an annuity on the life in expectation, gives the true present value of annuity on what may happen to remain of the latter of the two lives after the other. In the present case, the value of the annuity to be enjoyed during the joint continuance of two lives, each

forty years of age, is by Table II. 9·826, according to the probabilities of life in the Table of Observations, formed by Dr. Halley from the bills of mortality of Breslaw in Silesia. The value of a single life forty years of age, as given by M. de Moivre, agreeably to the same table, is 13·20; and the former subtracted from the latter, leaves 3·37, or the true number of years' purchase, which ought to be paid for any given annuity, to be enjoyed by a person forty years of age, provided he survives another person of the same age, interest being reckoned at four per cent. per annum. The annuity therefore being £30, the present value of it is 30 multiplied by 3·37, or £101 2s. IV. If, instead of a single present payment, it is thought preferable to make annual payments during the marriage; what these annual payments ought to be, is easily determined by finding what annual payments during two joint lives of given ages are equivalent to the value of the reversionary annuity in present money. Suppose, as before, that the joint lives are each forty, and the reversionary annuity £30 per annum. An annual payment during the continuance of two such lives is worth 9·82 years' purchase. The annual payment ought to be such as, being multiplied by 9·82, will produce £101 the present value of the annuity in one payment. Divide then 101 by 9·82, and 10·3 the quotient will be the annual payment. This method of calculation supposes that the first annual payment is not to be made till the end of a year. If it is to be made immediately, the value of the joint lives will be increased one year's purchase; and, therefore, in order to find the annual payments required, the value of a present single payment must be divided by the value of the joint lives increased by unity. If the society prefer paying part of the value in a present single payment on admission, and the rest in annual payments; and if they fix these annual payments at a particular sum, the present single payment paid on admission is found by subtracting the value of the annual payment during the joint lives from the whole present value of the annuity in one payment. Suppose, for instance, the annual payments to be fixed at five guineas, the annuity to be £30, the rate of interest four per cent., and the joint lives each forty: the value of the annuity in one present single payment is £101·1. The value of five guineas or 5·25 per annum, is (5·25 multiplied by 9·82, the value of the joint lives) 51·55; which, subtracted from £101·1, gives 49·5, the answer. V. If a society takes in all the marriages among persons of a particular profession within a given district, and subjects them for perpetuity to a certain equal and common tax or annual payments, in order to provide life annuities for all the widows that shall result from these marriages; since, at the commencement of such an establishment, all the oldest, as well as the youngest, marriages are to be entitled equally to the proposed benefit, a much greater number of annuitants will come immediately upon it than would come upon any similar establishment which limited itself in the admission of members to persons not exceeding a given age. This will check that accumulation of given money which should take place at first, in order

to produce an income equal to the disbursements at the time when the number of annuitants comes to a maximum; and therefore will be a particular burden upon the establishment in its infancy. For this some compensation must be provided; and the equitable method of providing it is, by levying fines at the beginning of the establishment on every member exceeding a given age, proportioned to the number of years which he has lived beyond that age. But if such fines cannot be levied, and, if every payment must be equal and common, whatever disparity there may be in the value of the expectations of different members, the fines must be reduced to one common one, answering as nearly as possible to the disadvantage, and payable by every member at the time when the establishment begins. After this, the establishment will be the same with one that takes upon it all at the time they marry; and the tax or annual payment of every member adequate to its support, will be the annual payment during marriage due from persons who marry at the mean age at which, upon an average, all marriages may be considered as commencing. The fines to be paid at first are, for every particular member, the same with the difference between the value of the expectation to him at his present age, and what would have been its value to him had the scheme begun at the time he married. Or, they are, for the whole body of members, the difference between the value of the common expectation, to persons at the mean age of all married persons taken together as they exist in the world, and to persons at that age which is to be deemed their mean age when they marry. VI. Suppose we wish to know the present value of an annuity to be enjoyed by one life, for what may happen to remain of it beyond another life, after a given term; that is, provided both lives continue from the present time to the end of a given term of years; the method of calculating is this:—Find the value of the annuity for two lives, greater by the given term of years than the given lives; discount this value for the given term; and then multiply by the probability that the two given lives shall both continue the given term; and the product will be the answer. Thus, let the two lives be each thirty, the term seven years, the annuity £10 interest for four per cent. The given lives, increased by seven years, become each thirty-seven. The value of two joint lives, each thirty-seven, is (by Table II.) 10·25. The value of a single life at thirty-seven is 13·67. The former subtracted from the latter is 3·42, or the value of an annuity for the life of a person thirty-seven years of age, after another of the same age, as has been shown above: 3·42 discounted for seven years (that is, multiplied by 0·76 the value of £1 due at the end of seven years) is 2·6. The probability that a single life at thirty shall continue seven years is $\frac{1}{3}$.* The

* The probability that a given life shall continue any number of years, or reach a given age, is (as is well known) the fraction whose numerator is the number of the living in any table of observations opposite to the given age, and denominator the number opposite to the present age of the given life.

probability, therefore, that two such lives shall continue seven years, is $\frac{301}{315}$ or in decimals 0.765; and, 2.6 multiplied by 0.765 is 1.989, the number of years' purchase which ought to be given for an annuity to be enjoyed by a life now thirty years of age, after a life of the same age, provided both continue seven years. The annuity then being £10, its present value is £19.89. Suppose the value is required of an annuity to be enjoyed for what may happen to remain of one life after another, provided the life in expectation continues a given time. 1. Find the present value of the annuity for the remainder of the life in expectation after the given time, which is done in this manner:—Multiply the present value of the life at the given time by the present value of £1 to be received at that time, and multiply the product again by the probability that the life in expectation will continue so long. Let the given time which the life in expectation is to continue be fifteen years, and let the person then be arrived at fifty years of age. A life at fifty according to M. de Moivre's valuation of lives, and reckoning interest at four per cent., is worth 11.34 years' purchase. The present value of £1, to be received at the end of fifteen years, is 0.5553, and the probability that a life at thirty-five will continue fifteen years is $\frac{146}{150}$. These three values multiplied into one another give £4.44 for the present value of the life in expectation. 2. Find the value of the reversion, provided both lives continue the given time, by the rule given above. 3. Add these values together, and the sum will be the answer in a single present payment. We shall now illustrate this rule by an example. An annuity of £10, for the life of a person now thirty, is to commence at the end of eleven years, if another person now forty should be then dead; or, if this should not happen at the end of any year beyond eleven years in which the former shall happen to survive the latter: What is the present value of such an annuity, reckoning interest at four per cent., and taking the probabilities of life as they are in Dr. Halley's table given in the article MORTALITY? The value of £10 per annum, for the remainder of the life of a person now thirty, after eleven years is £69.43. The probability that a person forty years of age shall live eleven years, is, by Dr. Halley's table, $\frac{315}{315}$. The probability, therefore, that he will die in eleven years, is $\frac{4}{315}$ subtracted from unity*, or $\frac{146}{315}$; which multiplied by £69.43, gives £17.16.—The value of the reversion, provided both live eleven years, is £17, and this value added to the former makes £34.16, the value required in a single present payment; which payment divided by £11.43, the value of two joint lives, aged thirty and forty, with unity added gives £3; or the value required in annual payments during the joint lives, the first payment to be made immediately.

The values of joint lives in these tables have been computed for only one rate of interest; and of single lives in Table III. for only two

rates of interest. The following rules will show that it would be a needless labor to compute these values (in strict conformity to the observations) for any other rates of interest. Account of a method of deducing, from the correct values (according to any observation) of any single or joint lives at one rate of interest, the same values at other rates of interest.

PRELIMINARY PROBLEMS.

PROB. I.—The expectation given of a single life by any table of observations, to find its value, supposing the decrements of life equal, at any given rate of interest. *Solution*.—Find the value of an annuity certain for a number of years equal to twice the expectation. Multiply this value by the perpetuity increased by unity, and divide the product by twice the expectation: the quotient subtracted from the perpetuity will be the value required. *Example*.—The expectation of a male life aged ten, by the Sweden observations, is 43.94. Twice this expectation is 87.88. The value of an annuity certain for 87.88 years is (reckoning interest at four per cent.) 24.200. The product of 24.200 into 26 (the perpetuity increased by unity) is 629.2 which divided by 87.88 gives 7.159. And this quotient subtracted from 25 (the perpetuity) gives 17.84 years' purchase, the value of a life aged ten, deduced from the expectation of life at that age according to the Sweden observations. (See the tables in Dr. Price on Reversions, v. iii.)

PROB. II.—Having the expectations given of any two lives, by any table of observations, to decide thence the value of the joint lives at any rate of interest, supposing an equal decrement of life. *Solution*.—Find the difference between twice the expectation of the youngest life and twice the expectation of the oldest life, increased by unity and twice the perpetuity. Multiply this difference by the value of an annuity certain for a time equal to twice the expectation of the oldest life; and by twice the same expectation divide the product, reserving the quotient. From twice the perpetuity subtract the reserved quotient, and multiply the remainder by the perpetuity increased by unity. This last product, divided by twice the expectation of the youngest life, and then subtracted from the perpetuity, will be the required value. When twice the expectation of the youngest life is greater than twice the expectation of the oldest life increased by unity, and twice the perpetuity, the reserved quotient, instead of being subtracted from twice the perpetuity, must be added to it, and the sum, not the difference, multiplied by the perpetuity increased by unity. *Example*.—Let the joint lives proposed be a female life aged ten, and a male life aged fifteen; and let the table of observations be the Sweden table for lives in general, and the rate of interest four per cent. Twice the expectations of the two lives are 90.14 and 83.28. Twice the expectation of the oldest life, increased by unity, and twice the perpetuity, is 134.28, which lessens by 90.14 (twice the expectation of the youngest life), leaves 44.14 for the reserved remainder. This remainder, multiplied by 24.045 (the value of an annuity certain for 83.28 years), and the

* For the difference between unity and the fraction expressing the probability that an event will happen, gives the probability that it will not happen.

product divided by 83·28 (twice the expectation of the oldest life), gives 12·744, the quotient to be reserved; which, subtracted from double the perpetuity, and the remainder (or 37·255) multiplied by the perpetuity increased by unity (or by 26) gives 968·630, which, divided by 90·14 (twice the expectation of the youngest life), and the quotient subtracted from the perpetuity, we have 14·254 for the required value. The value of an annuity certain, when the number of years is a whole number with a fraction added (as will be commonly the case) may be best computed in the following manner:—In this example the number of years is 83·28. The value of an annuity certain for eighty-three years is 24·035. The same value for eighty-four years is 24·072. The difference between these two values is 0·37; which difference, multiplied by ·28 (the fractional part of the number of years), and the product (·0103) added to the least of the two values, will give 24·045 the value for 83·28 years. *General Rule.*—Call the correct value (supposed to be computed for any rate of interest) the first value. Call the value deduced (by the preceding problems) from the expectations at the same rate of interest the second value. Call the value deduced from the expectations for any other rate of interest the third value. Then the difference between the first and second values added to or subtracted from the third value, just as the first is greater or less than the second, will be the value at the rate of interest for which the third value has been deduced from the expectations. The following examples will make this perfectly plain. *Example I.*—In the two last tables the correct values are given of two joint lives among mankind at large, without distinguishing between males and females, according to the Sweden observations, reckoning the interest at four per cent. Let it be required to find from these values the values at three per cent. and let the ages of the joint lives be supposed 10 and 10. The correct value, table IV. (reckoning interest at four per cent.), is 16·141. The expectation of a life aged ten is 45·07. The value deduced from this expectation at four per cent. by prob. II. is 14·539. The value deduced by the same problem from the same expectation at three per cent. is 16·808. The difference between the first and second values is 1·602, which, added to the third value (the first being greater than the second), makes 18·410, the value required. *Example II.*—Let the value be required of a single male life aged ten, at three per cent. interest, from the correct value at four per cent. according to the Sweden observations. First, or correct value, at four per cent. (by table III.) is 18·674. The expectation of a male life aged ten is 43·94. The second value (or the value deduced from this expectation by prob. I.) is 17·838. The third value (or the value deduced from the same expectation at three per cent.) is 21·277. The difference between the first and second is ·836; which (since the first is greater than the second) must be added to the third; and the sum (that is, 22·113) will be the value required. The third value at five per cent. is 15·286; and the difference added to 15·286 makes 16·122 the value of a male life

aged ten at five per cent. according to the Sweden observations. The exact value at five per cent. is (by table III.) 16·014. Again: the difference between 16·014 (the correct value at five per cent.) and 15·286 (the value at the same interest deduced from the expectation), is ·728; which, added (because the first value is greater than the second) to 13·335 (the value deduced at six per cent. from the expectation) gives 14·063, the value of the same life, reckoning interest at six per cent. These deductions, in the case of single lives particularly, are so easy, and give the true values so nearly, that it will be scarcely ever necessary to calculate the exact values (according to any given observations) for more than one rate of interest. If, for instance, the correct values are computed at four per cent. according to the observations, the values at 3, 3½, 4½, 5, 6, 7, or 8 per cent. may be deduced from them by the preceding rules as occasion may require, without much labor or any danger of considerable errors. The values thus deduced will seldom differ from the true values so much as a tenth of a year's purchase. They will not generally differ more than a twentieth or thirtieth of a year's purchase. In joint lives they will differ less than in single lives, and they will come equally near to one another whatever the rates of interest are. The following tables furnish the means of determining the exact differences between the values of annuities, as they are made to depend on the survivorship of any male or female lives; which hitherto has been a desideratum of considerable consequence in the doctrine of life annuities. What has made this of consequence is chiefly the multitude of societies lately established in this and foreign countries for providing annuities for widows. The general rule for calculating from these tables the value of such annuities is the following:—*Rule:* 'Find in table III. the value of a female life at the age of the wife. From this value subtract the value in table IV. of the joint continuance of two lives at the ages of the husband and wife. The remainder will be the value in a single present payment of an annuity for the life of the wife should she be left a widow. And this last value divided by the value of the joint lives increased by unity, will be the value of the same annuity in annual payments during the joint lives, and to commence immediately.' *Example.* Let the age of the wife be twenty-four, and of the husband thirty. The value in table III. (reckoning interest at four per cent.) of a female life aged twenty-four, is 17·252. The value in table IV. of two joint lives, aged twenty-four and thirty, is 13·455; which, subtracted from 17·252, leaves 3·797, the value in a single present payment of an annuity of £1 for the life of the wife after the husband; that is, for the life of the widow. The annuity therefore being supposed £20, its value in a single payment is 20 multiplied by 3·797, that is, £75·94. And this last value, divided by 14·455 (that is, by the value of the joint lives increased by unity), gives 5·25, the value in annual payments beginning immediately, and to be continued during the joint lives of an annuity of £20 to a wife aged twenty-four for her life, after her husband aged thirty.

TABLE I.—Showing the Present Value of an Annuity of £1 on a single life, according to M. de Moivre's Hypothesis.

Upon this subject we have been waiting (see the article LIFE ANNUITIES) for the long promised new tables of Mr. Babbage: they have not yet appeared. We can therefore at present only furnish the reader with the former data, above given. It is probable that these important contributions to science may be forthcoming in time, to be added to a few Supplementary Articles of which we have memoranda.

SURYA, in the Hindoo mythology, is the common name of the sun, or of a personification of that luminary. This luminary, as in all idolatrous nations, appears to have been invoked by the lower classes superstitiously; but by brahmins and the initiated it is asserted typically of that 'divine and incomparably greater light which illumines all, delights all, from which all proceed, to which all must return, and which alone can irradiate (not our visual organs merely, but our souls and) our intellects.' These, as we are told by Sir W. Jones, may be considered as the words of the most sacred text in Indian scripture.

For we must not be surprised, as remarked by the same author, at finding that, on a close examination, the characters of all the pagan deities, male and female, melt into each other, and at last into one or two. It seems a well-founded opinion that the whole crowd of gods and goddesses, in ancient Rome and modern Benares, mean only the powers of nature, and principally those of the sun, expressed in a variety of ways, and by a multitude of fanciful names. A plausible opinion has been entertained by learned men, that the principal source of idolatry among the ancients was their enthusiastic admiration of the sun; and that when the primitive religion of mankind was lost amid the distractions of establishing regal governments, or neglected amid the allurements of vice, they ascribed to the great visible luminary, or to the wonderful fluid of which it is the general reservoir, those powers of pervading all space, and animating all nature, which their wise ancestors had attributed to one Eternal Mind, by whom the substance of fire had been created as an inanimate and secondary cause of natural phenomena. The mythology of the east confirms this opinion. Still the noble truth, so well expressed in the concluding stanza of an ode addressed to Surya by Sir William, is fully recognized by intelligent Hindoos.

' Though the Sanscrit song
Be strown with fancy's wreaths
And emblems rich, beyond low thoughts refin'd,
Yet heav'nly truth it breathes
With attestation strong,
That, loftier than thy sphere, th' Eternal Mind,
Unmov'd, unrival'd, undefled,
Reigns with providence benign.—
—Since thou, great orb, with all-enlightening ray,
Rul'st the golden day,
How far more glorious He, who said serene,
Be—and thou wast—Himself unform'd, unchang'd,
unseen'

We find the Hindoos ascribing to Surya the properties or attributes of the three persons or powers that coalesce mythologically and form

their Trimurti, or Trinity, as it has been usual to call it, or that, physically contemplated, are the secondary causes of natural phenomena. One of the names of the sun is Treyitenu, or in shortness Trintu, meaning three-bodied, as embracing the creative power of Brahma in his capacity of producing forms by his genial heat; the preservative power of Vishnu in the property of light; and the destructive energy of Siva in the concentrated force of his igneous matter. And these are in fact the attributes of the one God, the Eternal Mind, of Hindoo theologians, who is called Brahm. The sun, or Surya, is therefore declared to be Brahma, Vishnu, and Siva. At night and in the west he is Vishnu; he is Brahma in the east and in the morning; from noon to evening he is Siva.

In pictures Surya is usually represented four-handed, seated in a golden car drawn by seven green horses, a nimbus encircling his head, and sometimes blazing round the whole. Sometimes his car is drawn by one horse with seven heads. A legless charioteer, with a red face, named Aruna, guides the chariot with reins of variegated hue.

Surya's seven horses, as well as Aruna's variegated reins, are supposed to have reference to the tints of his preceding ray; but we have yet to learn if the Hindoos have attained a knowledge of optics, warranting a supposition of their being acquainted with a prismatic divisibility of a ray of light. The regents of the sun and of fire, intimately connected as their primary properties are, we may expect to find agreeing in their emblems or attributes. Thus Surya's 'mystic orb triform,' and Agnis 'triplicate of legs,' are deducible from the three descriptions of sacred fires venerated by the Hindoos, and proceeding from, and re-absorbed in, the sun, as the three great powers of nature proceed from, and return to, the Eternal Mind. We may thus discern an additional reason for a people of idolatrous propensities identifying the sun with Brahm, or that being who said BE! and the sun was. Surya's seven horses, and Agnis seven legs, are again referrible to the idea of the common properties of light and heat.

The theory of the learned author of the Analysis of Ancient Mythology would have derived a considerable accession of strength in his mind, had he been possessed of the speculation of the Hindoos on the universality of the sun. Sir W. Jones, not altogether agreeing with Newton, that ancient mythology is nothing but historical truth in a poetical dress; nor with Bacon, that it consisted in moral and metaphysical allegories; nor with Bryant, that all the heathen deities are only different attributes and representations of the sun, or of deceased progenitors; reasonably conceived that the whole system of religious fables rose, like the Nile, from several distinct sources; and inclined to the opinion, that one great spring and source of idolatry, in the four quarters of the globe, was the veneration paid by men to the sun; and another, the immoderate respect shown to the memory of deceased ancestors, especially the founders of kingdoms, legislators and warriors,

of whom the sun and moon were wildly supposed to be the parents.

But although the sun is found in the Hindoo system to include the three great powers, Surya externally more resembles Vishnu than either of the others. His forehead is marked with the sectarial hieroglyphic of the Vaishnavas, that is, with perpendicular lines; the Saivas, or sectarists of Siva, marking their and their gods' foreheads with horizontal lines. Surya is also frequently seen with Vishnu's commonest attributes, the shank or shell, and lotos. Vishnu is farther considered as more immediately the sun than either Brahma or Siva; and his most glorious incarnation in the person of Krishna is of direct solar reference. Among the names of Surya will be found both Vishnu and Krishna; and it may be here remarked, on the authority of general Vallencey, that Krishna is the sun in Irish as well as in Sanscrit; and Arun is the precursor of the sun (that is, the dawn, Aurora) both in Irish and Hindoo mythology. The various names of the sun, among the Hindoos, amount it is said to nearly fifty. It may lead to some curious speculation to consider that the primary name of the sun means the attractor. See Sir William Jones's admirable Essay on the Philosophy of the Asiatics, in the fourth volume of the Asiatic Researches, and in his works edited by lord Teignmouth.

Surya has wives assigned him, termed Sakti. The consort that we oftener read of is Prabha, which means brightness or effulgence. The Hindoos, like some other distant people, consider the moon as a male deity; and, as conjunctions of the sun and moon are a common language with all astrologers and mythologists, we find sexual fables invented for bringing them together, and into separations, or oppositions. The sun and moon are therefore both male and female with the Hindoos, and are duly married, separated, &c. The Greeks had similar tales. See Potter's Arch. Græc. c. xix.

We are told, by Mr. Turner, that among the Anglo-Saxons the moon was a male and the sun a female deity; and the same peculiarity of gender, the author says, obtained in the ancient northern language. It is curious, he further remarks, that in a passage of an Arabian author (in Not. ad Carmen Tograi, p. 13.) we meet with a female sun and masculine moon. The distich is,—

Nec nomen fœmininum Soli dedecus,
Nec masculinum Lunæ gloria.

There is also a solar race in Hindoo fable, like the Heliades of Greece, and the similar families of the Peruvians. Suryavansa, or offspring of Surya, is the Sanscrit designation of these illustrious descendants. The river Yamuna, called Jumna by European geographers, is styled in Hindoo poetics 'the blue-eyed daughter of the sun.'

Representations of Surya are very common throughout India, in pictures, sculptures, and casts; both separately and associated with other deities. Several engravings of him in both situations are given in the Hindoo pantheon, from the three several originals. He is seen seated

in his car, surrounded by a blaze of glory, drawn by seven foaming steeds, or by one seven-headed, drawn by the imperfect dawn, Aruna. And he is described as followed by thousands of geni, worshipping him and modulating his praises. The following is a translation of the first verse of a hymn addressed, with oblations, to the regents of the nine planetary spheres, extracted from Colebrook's Essay on the Religious Ceremonies of the Hindoos, in the seventh volume of the Asiatic Researches:—'The divine sun approaches with his golden car, returning alternately with the shades of night; rousing mortal and immortal beings, and surveying worlds. May this oblation to Surya be efficacious!' In some zodiacal representations, Surya is mounted on a lion, and placed in the centre, indicating an early knowledge of the true solar system. His car is sometimes followed by a black ill-favored figure, a personification, probably, of the darkness that the god of day is dispelling.

SUS, the hog, in zoology, a genus of quadrupeds, belonging to the class of mammalia and order of belluæ. There are four cutting teeth in the upper jaw, whose points converge; and, for the most part, six in the lower jaw, which stand forwards. There are two tusks in each jaw, those in the upper jaw being short, while those of the under jaw are long, and extend out of the mouth. The snout is prominent, moveable, and has the appearance of having been cut off or truncated. The feet are armed with divided or cloven hoofs. There are six species:—

1. S. Æthiopicus, the engallo, or Ethiopian hog, has no fore teeth, but small tusks in the lower jaw, very large ones in the upper, in old boars bending towards the forehead in form of a semi-circle: nose broad, depressed, and almost of a horny hardness: head very large and broad; beneath each eye a hollow, formed of loose skin, very soft and wrinkled; under these a great lobe or wattle, lying almost horizontal, broad, flat, and rounded at the end, placed so as to intercept the view of any thing below from the animal. Between these and the mouth, on each side, there is a hard callous protuberance. The mouth is small; skin dusky; bristles disposed in fasciculi, of about five each; longest between the ears and on the beginning of the back thinly dispersed on the rest of the back. Ears large and sharp pointed, inside lined with long whitish hairs; tail slender and flat, not reaching lower than the thighs, and is covered with hairs disposed in fasciculi. Body longer, and legs shorter than in the common swine; its whole length four feet nine inches; height before two feet two inches; but in a wild state it grows to an enormous size. These animals inhabit the hottest parts of Africa, from Senegal to Congo, also the island of Madagascar. They are very fierce, active, and swift; they will not breed with the domestic sow. They burrow under ground, into which they dig with surprising expedition. Buffon confounds this with the African.

2. S. Africanus, the African hog, has only two fore teeth in the upper jaw, and six in the lower; on each side six grinders. The body is covered

with very long and fine bristles; the tail reaches to the first joint of the hind leg; is very slender, and ends in a large tuft; the head is long; nose slender; the upper jaw extending far beyond the lower; the ears narrow, erect, and pointed, with very long bristles at the end. They inhabit Africa, from Cape Verd to the Cape of Good Hope.

3. *S. babyrussa*, the Indian hog, has four cutting teeth in the upper, six in the lower jaw; ten grinders to each jaw; in the lower jaw two tusks pointing towards the eyes, and standing nearly eight inches out of their sockets; from two sockets on the outside of the upper jaw two other teeth, twelve inches long, bending like horns, their ends almost touching the forehead; ears small, erect, sharp-pointed; along the back are some weak bristles; on the rest of the body only a sort of wool, such as is on lambs; the tail long, ends in a tuft, and is often twisted: the body plump and square. It inhabits Buero, a small isle near Amboyna; it is also found in Celebes, but neither on the continent of Asia nor Africa. They are sometimes kept tame in the Indian isles; live in herds; have a very quick scent; feed on herbs and leaves of trees; never ravage gardens like other swine; their flesh well tasted. When pursued, and driven to extremities, they rush into the sea, swim very well, and even dive, and pass thus from isle to isle. In the forests they often rest their heads, by hooking their upper tusks on some boughs. The tusks, from their form, are useless in fight.

4. *S. porcus*, the Guinea hog, has no bristles; the hinder part of the back is covered with long hairs; the tail is long and naked, and hangs down to the ground; the ears are longish and much pointed; the body is covered with short and shining red hairs. This species inhabits Guinea. There is a variety called the Siamese hog. Both are smaller than the common hog.

5. *S. scrofa*, the common hog, having the body covered with bristles; two large teeth above and below. There are four varieties:—

i. *S. scrofa domesticus*, the domestic hog, has the ears long, sharp-pointed, and slouching; the color generally white, sometimes mixed with other colors. In a tame state it is universal, except in the frigid zones, and in Kamschatka, where the cold is very severe. Since its introduction into America by the Europeans, it abounds to excess in the hot and temperate parts. Of all quadrupeds the hog is the most rude and brutal. All his habits are gross; all his appetites are impure; all his sensations are confined to a furious lust and a brutal gluttony. He devours indiscriminately every thing that comes in his way, even his own progeny the moment after their birth. This voraciousness seems to proceed from the perpetual cravings of his stomach, which is of an immoderate size; and the grossness of his appetites, it is probable, arises from the bluntness of his senses of taste and of feeling. The rudeness of the hair, the hardness of the skin, and the thickness of the fat, render these animals less sensible to blows. Mice have been known to lodge upon a hog's back, and to eat his skin and fat, without his showing any marks of feeling. The other senses of the hog

are very good. It is well known to the hunters that the wild boar hears and smells at a great distance; for, to surprise him, they are obliged to watch him in silence during the night, and to place themselves opposite to the wind, that he may not perceive the smell, which never fails to make him turn back. The parts of this animal are finely adapted to its way of life. As its method of feeding is by turning up the earth with its nose for roots of different kinds, so it has a more prone form than other animals; a strong brawny neck; eyes small, and placed high in the head; a long snout, nose callous and tough, and a quick sense of smelling to trace out its food. Its intestines have a strong resemblance to those of the human species. Notwithstanding its powers of motion, it is by nature stupid, inactive, and drowsy; much inclined to increase in fat, which is disposed in a different manner from that of other animals, and forms a regular coat over the whole body. It is restless at a change of weather, and in high winds is so agitated as to run violently, screaming horribly at the same time; it is fond of wallowing in the dirt, either to cool its surfeited body, or to destroy the lice, ticks, and other insects with which it is infested. Its diseases generally arise from foul feeding and intemperance; such as measles, imposthumes, and scrophula. These are best prevented by keeping the animals, as the ancients strongly recommended, very clean in their sties; allowing them air, exercise, and a sufficiency of water. Linnæus observes that its flesh is wholesome food for athletic constitutions, or those that use much exercise; but bad for such as lead a sedentary life; it is, however, of most universal use, and furnishes numberless materials for epicurism. The boar, or male, is chosen with great care, when intended for propagation; and is thus employed from the age of two to five years, and then either sold or fattened. The males not allotted to this use are castrated, sometimes at the age of six weeks, sometimes six months; and then fed to a great size either for sale or for use. Sows are kept for breed generally from one year old to seven, and are then fattened. They have commonly more grease on their intestines than hogs, these being fattest on their backs. Aristotle says, that hogs in general live twenty years; and adds that both males and females are fertile till they arrive at fifteen. They can engender at nine or twelve months; but it is better to restrain them till they be eighteen months or two years. The first litter of the sow is not numerous; and, when only one year old, her pigs are weak, and even imperfect. She may be said to be in season at all times. Though impregnated, she solicits the approach of the male, which is an excess among animals; for almost every other species refuse the male after conception. The ardor of the sow, though almost perpetual, is however marked by paroxysms and immoderate movements, which always terminate by her wallowing in the mire. She, at the same time, emits a thick whitish fluid. She goes four months with young; brings forth in the beginning of the fifth; and soon after solicits the male, is impregnated a second time, and thus brings forth twice a-year. Only eight

or nine of the litter are kept; the rest are sold. In fifteen days pigs are excellent food. The flesh of all the different species of swine, and at all ages, is a very substantial and agreeable aliment; and, in their proper seasons, the different sorts of provisions thus supplied are all of them very saleable. The flesh was much more in favor with our ancestors than with us; though brawn has still many admirers, is made in the greatest perfection, and considered as a rarity peculiar to this country. Pork, though it might be wisely prohibited in some warm countries, is found equally nutritive and salutary here. As such it furnishes a very large proportion of that food which is vended in our markets. It takes salt better, and keeps longer, than the flesh of any other animal; and the consumption of it is prodigious when pickled or salted, more especially in our foreign garrisons and in the sea service. Our bacon is differently cured, so as to render it acceptable to all palates; and our hams are not at all inferior to those of other countries. Fresh pork sells nearly as dear as beef; the lard brings double or triple the price; the blood, the intestines, the feet, and the tongue, are all prepared as food. The fat of the intestines and web, which differs from common lard, is employed for greasing axles of wheels, and for many other purposes. Sieves are made of the skin; and brushes, pencils, &c., of the bristles. The dung is reputed next in value to that of sheep. Mr. Worlidge proposes that swine should be turned into a close well-paled, and planted with greens, pulse, and roots, on which they may feed, and by their trampling and their dung raise a great quantity of excellent soil. Mr. Mortimer assures us that some on poor light shallow land in Staffordshire sow a small white pea, which they never reap, but turn in so many hogs to eat them as they think they will fat; and there they lie day and night, and their dung will so enrich the land that it will bring a good sward upon it, and will graze many years afterwards. Our old husbandmen had an ill opinion of this dung, as supposing it bred weeds. In some places they wash with hogs' dung for want of soap; which answers tolerably well, if the linen hangs long enough in the air to become thoroughly sweet. The snout of an old boar is the only part that is esteemed; but every part of the castrated and young boar, not exceeding one year fed, makes delicate eating. The pork of the domestic boar is worse than that of the wild boar; and it can only be rendered fit for eating by castration and fattening.

ii. *S. scrofa dom. monungulus*, the single-hoofed hog, has undivided hoofs on all the feet, and resembles the common kind in every thing else. They inhabit Upsal in Sweden, and other places; and are mentioned by the ancients.

iii. *S. scrofa dom. Sinensis*, the Chinese hog, has the back almost naked, and the belly hanging down to the ground; the legs are short, and the tail short and pendulous. They are common in China, the islands in the Indian Ocean and South Sea, and in New Guinea. They are cultivated in Europe, and are much more cleanly than the common hog.

iv. *S. scrofa ferus*, the wild hog, is of a dark

brinded color, and beneath the bristles is a soft short hair; the ears short and a little rounded. It is found wild in most parts of Europe. In the forests of South America there are vast droves, which derive their origin from the European kind relapsed into a state of nature; and are what Mr. Bancroft, in his history of Guiana, describes as a particular species by the name of warree. They cannot bear excessive cold; inhabit wooded countries; and are very swift. In America they are useful by clearing the country of rattlesnakes, which they devour without danger. The external form of its body is very unwieldy; yet, by the strength of its tendons, the wild boar is enabled to fly from the hunters with amazing agility: the back toe on the feet of this animal prevents its slipping while it descends declivities, and must be of singular use when pursued. As to the age of these animals, it is said the life of the wild boar may be extended to twenty-five or thirty years. The flesh of the wild boar was esteemed a great delicacy by the ancient Romans. The wild sow, which every way resembles the domestic kind, produces only once a year. This difference in fertility is probably owing to want of nourishment, and the necessity of suckling her pigs much longer than the domestic sow, which is never allowed to nurse her young above fifteen days or three weeks. The wild boar was formerly a native of England, as appears from the laws of Hoel Dha, who permitted his grand huntsman to chase that animal from the middle of November to the beginning of December. William I. punished with the loss of their eyes any that were convicted of killing the wild boar, the stag, or the roebuck; and Fitz Stephen tells us that the vast forest that in his time grew on the north side of London was the retreat of stags, fallow-deer, wild boars, and bulls. Charles I. turned out wild boars in the New Forest Hampshire, but they were destroyed in the civil wars. On the continent the wild boar is hunted with dogs, or killed by surprise during the night, when the moon shines. As he runs slowly, leaves a strong odor behind him, and defends himself against the dogs, and often wounds them dangerously, fine hunting dogs are unnecessary, and would have their nose spoiled, and acquire a habit of moving slowly, by hunting him. Mastiffs, with very little training, are sufficient. The oldest, which are known by the track of their feet, should only be attacked: a young boar of three years old is difficult to hunt down, because he runs very far without stopping. But the older boars do not run far, allow the dogs to run near, and often stop to repel them. During the day, he commonly remains in his soil, which is in the most sequestered part of the woods. He comes out in the night in quest of food. In summer, when the grain is ripe, it is easy to surprise him among the cultivated fields, which he frequents every night. As soon as he is slain, the hunters cut off his testicles, the odor of which is so strong that in a few hours it would infect the whole flesh. The ancients castrated the young boars which they could carry off from their mothers, and returned them to the woods, where they grew fat, and their pork was much better than that of domestic hogs.

6. *S. tajassu*, the tajassu, peary, or Mexican hog, with four cutting teeth above, and six below; two tusks in each jaw; those in the upper jaw pointing down, and little apparent when the mouth is shut; the others hid: length from nose to the end of the rump about three feet: head not so taper as in common swine: ears short and erect: body covered with bristles, stronger than those of the European kind, and more like those of a hedge-hog; they are dusky, surrounded with rings of white; those on the top of the neck and back are nearly five inches long; shorter on the sides; the belly almost naked; from the shoulders to the breast is a band of white: no tail: on the lower part of the back is a gland, open at the top, discharging a fetid ichorous liquor; this has been by mistake called a navel. Inhabits the hottest parts of South America, and some of the Antilles: lives in the forests on the mountains: is not fond of mire or marshy places: less fat than the common hog. These animals go in great droves. They are very fierce, and will fight stoutly with the beasts of prey: the jaguar, or American leopard, is their mortal enemy; often the body of that animal is found, with several of these hogs, slain in combat. Dogs will scarcely attack this animal: if wounded, it will turn on the hunters. They feed on fruits and roots; also on toads and all manner of serpents, which they hold with their fore-feet, and skin with great dexterity. The flesh is reckoned very good food; but all writers agree that the dorsal gland must be cut out as soon as the animal is killed, or the flesh will become so infested as not to be eatable. The Indian name of this species is paquiras, whence is derived that of peary.

SUSA, or **SHUSHAN**, the ancient royal residence of the kings of Persia, built by Darius Hystaspis, according to Pliny; though he probably only restored it, being a very ancient city, founded by Tithonus, the father of Memnon. It was in compass 120 stadia, of an oblong quadrangular form, with a citadel called memnoneum. In Scripture it is called Shushan, the royal citadel, from the great number of lilies growing in that district (Athenæus); situate on the river Ulai or Eulæus (Daniel): Susa was the winter as Ecbatana was the summer residence of the kings of Persia (Xenophon, Strabo, Plutarch). Here the kings kept their treasure; and Alexander found immense riches in it (Herodotus). It is now called Suster.

SUSA, a province of Piedmont, with a superficial extent of 700 square miles, and 65,000 inhabitants. It consists of a broad valley at the foot of the Cottian Alps, interspersed with steep rocks and eminences. Its products are wine, chestnuts, fruit, silk, and corn. Grazing is also extensively followed. It has mines of iron and marble, and manufactures linen and leather.

SUSA, a fruitful province of Morocco, at its south extremity. There is not, perhaps, a finer climate in the world; its fruits are exquisite, particularly olives, the plantations of which are so extensive that a man may travel uninterruptedly through them for many days. The sugar cane is said to grow spontaneously. Cotton, indigo, and gums, are abundant. Stick-liquorice abounds to such a degree as to be called the root

of Suse. Almonds and olive oil are also produced for exportation.

SUSCEPTIBLE, *adj.* Fr. *susceptible*; Lat. **SUSCEPTIBILITY**, *n. s.* } *susceptus*. Prior has
SUSCEPTION, } accented this improp-
SUSCEPTIVE, *adj.* } perly on the first syl-
lable. Capable of admitting; disposed to admit: susceptibility, the quality of admitting: susception, the act of taking: susceptible, capable to admit.

He moulded him platonically to his own idea, delighting first in the choice of the materials, because he found him *susceptible* of good form.

Wotton.

The *susceptibility* of those influences, and the effects thereof, is the general providential law whereby other physical beings are governed.

Hale.

In their tender years they are more *susceptible* of virtuous impressions than afterwards, when solicited by vulgar inclinations.

L'Estrange.

Children's minds are narrow, and usually *susceptible* but of one thought at once.

Locke on Education.

Blow with empty words the *susceptible* flame.

Prior.

A canon, promoted to holy orders before he is of a lawful age for the *susception* of orders, shall have a voice in the chapter.

Ayliffe's Parergon.

Since our nature is so *susceptive* of errors on all sides, it is fit we should have notices given us how far other persons may become the causes of false judgments.

Watts's Logic.

SUSCITATE, *v. n.* Fr. *susciter*; Lat. *suscito*. To rouse; to excite.

It concurrerh but unto predisposed effects, and only *suscitates* those forms whose determinations are seminal, and proceed from the idea of themselves.

Browne's Vulgar Errors.

SUSPECT, *v. a., v. n., & n. s.* Lat. *suspicio, suspectum*. To imagine with a degree of fear and jealousy; imagine guilt; hold uncertain; doubt: as a participial adjective, doubtful: as a noun substantive, an obsolete synonyme of suspicion.

No fancy mine, no other wrong *suspect*,
Make me, O virtuous shame, thy laws neglect.

Sidney.

The sale of offices and towns in France,
If they were known, as the *suspect* is great,
Would make thee quickly hop without a head.

Shakspeare.

If I *suspect* without cause, let me be your jest.

Id.

There be so many false prints of praise, that a man may justly hold a *suspect*.

Bacon.

Nothing makes a man *suspect* much, more than to know little; and therefore men should remedy suspicion by procuring to know more.

Id.

Nothing more jealous than a favorite towards the waning time and *suspect* of satiety.

Wotton.

If the king ends the differences, and takes away the *suspect*, the case will be no worse than when two duellists enter the field.

Suckling

They might hold sure intelligence
Among themselves, without *suspect* t' offend.

Daniel.

Let us not then *suspect* our happy state,
As not secure.

Milton.

Sordid interests or affectation of strange relations are not like to render your reports *suspect* or partial.

Glanville.

SUSPEND', *v. a.*
 SUSPENSE', *n. s. & adj.*
 SUSPENSION', *n. s.*
 SUSPENSORY, *adj.*

Fr. *suspendre*; Lat. *suspendo*. To hang; to make to hang by any thing; make to depend upon: hence to interrupt; delay; keep undetermined. Suspense is uncertainty; delay; as an adjective, held in doubt: suspension, the act of hanging up; temporary cessation: suspensory, hanging by; that by which any thing is suspended.

The self-same orders allowed, but yet established in more wary and *suspense* manner, as being to stand in force till God should give the opportunity of some general conference what might be best for every of them afterwards to do.

Suspend your indignation against my brother, till you can derive from him better testimony of his intent.

Hooker.

Shakspeare.

To themselves I left them;
 For I *suspend* their doom.

Milton.

SUSPENSION, or SUSPENSE, in music, is produced by supposition, and is nearly the same. It consists in retaining as many as possible of the sounds in a preceding chord that they may be heard in that which succeeds.

SUSPENSION BRIDGES, in civil engineering, are now substituted, in a variety of cases, for the massive and costly structures of stone, some of which we have already described in our article BRIDGES. These bridges recommend themselves as well, by the economy and durability of their construction as by the simplicity and elegance of their appearance.

The first chain bridge in this country is believed to have been that of *Winch Bridge*, over the river Tees, which forms a communication between the counties of Durham and York. This bridge, of which we have given a view in fig. 1 plate II. SUSPENSION BRIDGES, is described by Hutchinson, in his *Antiquities of Durham*, 'as a bridge suspended upon iron chains stretched from rock to rock over a chasm nearly sixty feet deep, for the passage of travellers. It is seventy feet in length, and little more than two feet broad; with a hand-rail on one side, and planked in such a manner that the traveller experiences all the tremulous motion of the chain.'

The *King's Meadow Wire Bridge* (fig. 2), on the estate of Sir John Hay, bart., is thrown across the Tweed, a little below Peebles. This is likewise a foot-bridge. It is 110 feet in length, and four feet in breadth; and is ornamented with a handsome lodge, as is represented in the figure. This bridge was contracted for, and executed by Messrs. Redpath and Brown of Edinburgh, in the summer of 1817, and cost about £160. The lower ends of the hollow tubes, forming the piers on the opposite sides of the river, are secured by a brander or grating of timber laid under ground and shown in the connecting diagram marked *a* fig. 2.

The *Dryburgh Chain Bridge*, represented in fig. 3, is intended for foot passengers and led horses, and was built in 1817, in little more than four months, by Messrs. John and William Smith, architects near Melrose, at the expense of the earl of Buchan; and has altogether cost his lordship about £720. This bridge is 260 feet in extent between the points of suspension, and

four feet in breadth. On the 15th of January, 1818, this bridge, after it had been finished about six months, was completely destroyed by a violent gale of wind. The eyes formed on one end of the rods or links of the chains supporting the bridge were welded, but the other end was simply turned round and fixed with a collar as shown in the diagram marked *b* fig. 3. It deserves notice that, after the bridge fell, not more than one or two instances appeared of the iron having failed at the welded end; but it had uniformly broken at the open eye of the link as shown in the diagram *b*, above alluded to. The utility of Dryburgh Bridge, as contrasted with a troublesome ferry, having been on so short a trial sufficiently proved, his lordship ordered it to be rebuilt; and in less than three months it was again opened to the public. To this new bridge are added guys, or mooring chains, consisting of rods of iron fixed to stakes in the opposite banks of the river. These guys are attached to the beams of the roadway, as shown in the plan connected with fig. 3. They are said to have some effect in lessening the motion of the bridge in high winds. The post of piers, over which the catenarian chains pass, are formed of logs of memel timber fourteen inches square, erected in pairs as shown in the left hand diagram of fig. 3 marked 'approach of fig. 3.'

The work to which the reader's attention is next drawn is the *Union Chain Bridge*, across the river Tweed, at Norham Ford, about five miles from Berwick, as shown in fig. 4. This bridge was begun in August 1819, and opened on the 26th July, 1820; having required only a period of about twelve months for its erection, while a stone bridge must have been the work of about three years. It was designed and executed by captain Samuel Brown of the royal navy. It is eighteen feet in width, and no less than 361 feet in length. The roadway is suspended from the catenarian, or main chains, by circular rods one inch in diameter. These perpendicular rods are wedged into caps or pieces of cast iron called saddles, which are placed at the distance of five feet apart, and are made to rest upon the shackles or joints of the catenarian chains, as shown in the connecting diagram marked *c* fig. 4; 'the approach at fig. 4' represents an end view on the Scotch side of the river.

The gigantic structure crossing the *Menai Strait* is represented in plate II. SUSPENSION BRIDGES. It was commenced in 1821, and the first chain was thrown over in the month of April 1825. The extreme length of the chains, from the fastenings in the rocks at either extremity, is about 1600 feet; and the road consists of two carriageways of twelve feet each, with a foot-path of four feet in width in the centre. In the first examination of Mr. Rennie before the house of commons, in 1802, it was proposed to have a solid iron bridge with stone abutments; but Mr. Telford, the architect of the present structure, proved that the cost would have been incalculably greater by adopting Mr. Rennie's plan, while the power of resistance would have been less.

The suspension bridge at *Hammersmith* now remains to be described. The design is by Mr.

Tierney Clark, the engineer, and the whole has been executed under his direction. The following are the dimensions:—

	Feet. In.
The extent of water-way between the suspension towers rising from the bed of the river	400 3
The distance between these and the piers on shore are as follow:—	
On the Middlesex side	142 11
On the Surrey side	145 6
Leaving a clear water-way of	688 8

The suspension towers are forty-eight feet above the level of the road-way, where they are twenty-two feet thick. The road-way is slightly curved upwards, and is sixteen feet above high water; and the extreme length from the back of the piers on shore is 822 feet eight inches, supporting 688 feet of road-way; being 135 feet more than the Menai bridge. There are eight chains composed of wrought iron bars five inches deep, and one inch thick, each. Four of these chains have six bars in each chain, and four have only three bars in each chain, making in the total thirty-six bars which make a dip or curvature in the centre of about twenty-nine feet. From these, vertical rods are suspended, which support the road-way, formed of strong timbers covered with broken granite. The width of the carriage-way is twenty feet, with foot ways five feet wide. The chains pass over the suspension towers, and are secured to the piers on each shore. The suspension towers are built of stone, and designed as archways of the Tuscan order. The bridge has cost £80,000.

SUSPICION, *n. s.* } Fr. *suspicion*; Lat. *suspicio*. The act of
 SUSPICIOUS, *adj.* }
 SUSPICIOUSLY, *adv.* } suspecting; imagina-
 SUSPICIOUSNESS, *n. s.* } tion of ill: the adjective, adverb, and noun substantive corresponding.

They, because the light of his candle too much drowned theirs, were glad to lay hold on so colourable matter, and exceeding forward to traduce him as an author of *suspicious* innovations. *Hooker.*

Suspicion all our lives shall be stuck full of eyes, For treason is but trusted like a fox,
 Who, ne'er so tame, so cherished and locked up,
 Will have a wild trick of his ancestors. *Shakspeare.*

SUSPIRE', *v. n.* } Lat. *suspiro*. To sigh;
 SUSPIRATION, *n. s.* } to fetch the breath deep:
 it seems in Shakspeare to mean only to begin to breathe: the noun substantive corresponding.

Since the birth of Cain, the first male child,
 To him that did but yesterday *suspire*,
 There was not such a gracious creature born. *Shakspeare.*

Not customary suits of solemn black,
 Nor windy *suspuration* of forced breath,
 That can denote me truly. *Id.*

In deep *suspurations* we take more large gulphs of air to cool our heart, overcharged with love or sorrow. *More.*

SUSQUEHANNA, the largest river of Pennsylvania, North America, which is formed by the east and west branches. The east rises in Otsego Lake, New York, and the west in Huntingdon county Pennsylvania. They unite at Northumberland. The

river then runs south-east into the head of the Chesapeake, in Maryland. It is one mile and a quarter wide at its mouth, but it is navigable only five miles. The Susquehanna was surveyed in 1817 by commissioners appointed by Pennsylvania, who reported that below Columbia no ascending navigation was practicable, but that, at the expense of about 20,000 dollars, every obstacle might be removed to the head of the two branches. It is contemplated to unite the waters of this river with those of the Schuylkill.

SUSQUEHANNA, a county on the north side of Pennsylvania, bounded north by New York, east by Wayne county, south by Lucerne county, and west by Ontario county. Chief town Montrose.

SUSSEX, one of the southern counties of England, bounded on the west by Hampshire, on the north by Surrey, on the east and north-east by Kent, and on the south by the British Channel. It is seventy-six miles in length, and nearly twenty in average breadth. Towards Kent it is contracted to an obtuse point.

Sussex, like Surrey, is varied by the inequalities of the downs, with intervening valleys, through which the many little streams of the county pursue their respective courses; and the wooded scenery and pasture land give to the county in general a rural and a rich diversity of appearance. The tracts which come under the description of mere wastes, however, are very considerable. They occupy the northern side of the county, where, in a district containing by computation 500,000 acres, these almost desert tracts form not less than 110,000. Upon the downs the climate fronting is bleak, being exposed to violent winds, impregnated with saline particles. In the western part of the maritime district the climate is warm and highly favorable to the purposes of vegetation; in that called the Weald the climate is cold and damp.

In the easternmost parts of the Weald is found every sort of limestone; and the Sussex marble, when cut into slabs and polished, is equal to most kinds for beauty and quality. It is an excellent stone for square building and paving, and affords a very valuable manure. It is found from ten to twenty feet under ground, where it lies in strata nine or ten inches thick. The limestone has been found superior to both that of Maidstone and Plymouth; and for cement it is thought to surpass all other. Iron-stone abounds in this county; and to the ferruginous mixture with which its soil is in many places so highly impregnated, is to be ascribed the sterility of so large a portion of the surface. Chalk is still more plentiful, a vast range of hills which occupy a considerable part of the county contiguous to the coast being composed of it. On the south side of these hills marl is dug. Fuller's earth is found at Tillington and consumed in the neighbouring mills; and red ochre at Graffham, Chidham, and other places on the coast.

The rivers of Sussex are insignificant when compared with those of some other parts of the kingdom; but they are exclusively its own, as their origin and courses are confined within the limits of the county. All of them fall into the British Channel.

Sussex has, from the remotest antiquity, been celebrated for its oak. Before the Norman conquest it was one continued forest; and the quantity of woodland which it at present contains cannot be estimated at less than 170,000 acres. The reigning feature of the Weald is timber, which overspreads it in every direction. The quality of the timber may be collected from this circumstance, that the navy contractors are said to stipulate for Sussex oak in preference to every other. The roads of this county are in general good, being largely composed of whinstone and Kentish rag. There are no considerable canals in Sussex, but the Arun has been made navigable from the sea to its junction with the New Cut, a distance upwards of seventeen miles; and thence a company of merchants have extended it to Newbridge. A similar process has also been taken with the Rother, a branch of the former river, which constitutes part of a grand plan for connecting London with Sussex, by means of the junction of the Arun with the Wey at Guildford. A plan has also been proposed for cutting another canal from Newbridge on the Rother to Horsham, and thence to the iron railway at Mersham near Reigate in Surrey.

The proportion between pasture and arable land varies in different parts of this county. In the Weald a third is pasture, a third arable, and a third wood and waste. On the south side of the downs the arable exceeds the pasture in the proportion of thirty to one. The rotation of crops entirely depends upon the district. Some instances have occurred on very rich land where wheat has been repeated four or five years in succession, and the product amounted to four or five quarters per acre. The crops commonly raised in Sussex are wheat, oats, clover, turnips, peas, barley, and tares. The crops not commonly cultivated are beans, potatoes, buck-wheat, lettuces, hops, carrots, rhubarb, opium, sainfoin, lucerne, and chicory. The management of the meadow and pasture lands varies but little from the practices common in other counties; though here indeed there is but too much reason to complain of negligence with respect to the improvement of grazing land. Irrigation is but locally known; and it is only in the western parts of the county that any signs of it are to be observed. Very great improvements, however, have of late years been effected in the marshes situated along the coast, or in the neighbourhood of the rivers. In the western part of Sussex are some considerable orchards; and where the soil is adapted to the fruit, the plantations are thickly interspersed. The neighbourhood of Petworth yields the best cyder of any in the county. The manures used in Sussex, besides common dung, are chalk, lime, marl, slesch, soap-ashes, wood-ashes, peat-ashes, coal-ashes, rags, sheep-clippings, pilchards, paring-dust, and gypsum. The first three are applied in great abundance; the rest, from their nature, but partially.

Sussex is celebrated for its breed of sheep, which are fed on the south downs, and require but a very slight quantity of food for their subsistence. Their wool is little, if at all, inferior to that of the Hereford sheep, and their

hardiness is demonstrated by their healthiness and freedom from losses. The total amount of the sheep kept in the county is about 450,000. The largest estate in Sussex does not greatly exceed £7500 per annum, and most of the proprietors hold their land in their own occupation.

The principal manufacture in this county was the making of iron into bars; but this has decayed on account of the great establishments in Scotland and Wales, where, by the use of pit-coal, the article is supplied at a much cheaper rate. The county contains many Roman and some British antiquities. The Ermine Street, one of the eight British roads, led from this coast to the south-east part of Scotland. Here also was the Stane Street of the Romans, which passed from east to west of the county, with a vicinal, or branching road, towards Porchester. There are also many remains of Roman encampments situated in the vicinity of the downs, and overlooking the Weald. Mr. Dallaway, in his History of Western Sussex, recounts eleven of these relics of early encampment. Over the downs, and other parts of Sussex, are scattered various tumuli, or barrows, which, when opened, have been found to contain either bones, urns, or entire skeletons. Sussex, and the adjoining counties of Hants and Surrey, were by the Romans denominated *Belgæ*, from the circumstance of their being inhabited by a people so called. These were afterwards joined by the *Regni*, who settled in the same district antecedent to the invasion of England by Julius Cæsar. After that event, during the Roman dominion of Britain, there were four large stations or towns in Sussex, which included the minor tribes of the *Bibroci* and the *Rhemi*. Under the Britons Sussex formed a part of the *Suth-Seaxna-ric*, as already mentioned in Surrey; and by a similar modulation has been reduced to its present sound. Like the other counties of England Sussex was, at the Norman invasion, divided into lordships and assigned to some of the followers of king William. At that period the title of the earl of Sussex was given to one of these, and the title continued till 1801. It was then constituted a dukedom, and given to Augustus Frederick, sixth son of his late majesty.

The general division of Sussex is into rapes, a division peculiar to this county. These rapes, each of which is said to have had its particular castle, river, and forest, are Chichester, Arundel, and Bramber, forming the western; and Lewes, Pevensey, and Hastings, the eastern portion. The rapes are subdivided into sixty-five hundreds, and comprehend 313 parishes. Chichester is the chief town. Sussex sends eighty members to parliament, four for the county, two each for Chichester, Brighton, Hastings, Lewes, New Shoreham, and one each for Arundel, Horsham, Midhurst, and Rye.

SUSSEX, a county of the United States in New Jersey, bounded N. N. E. by New York, south-east by Bergen, Morris, and Hunterdon counties, and west and north-west by the Delaware, which separates it from Pennsylvania. Chief town, Newton.

SUSSEX, a county of Delaware, United States, bounded north by Kent county, east by Dela-

ware Bay and the Atlantic, south and west by Maryland. Chief towns Georgetown and Lewistown.

SUSSEX, a county of Virginia, bounded north-east by Surrey county, S. S. E. by Southampton county, south-west by Greensville county, and north-west by Dinwiddie and Prince George counties.

SUSTAIN', *v. a.* Fr. *soustenir*; Lat. *sustiner*.
 SUSTAIN'ER, *n. s.* } *neo.* To bear; prop; hold
 SUSTENANCE, } up; maintain; endure; suf-
 SUSTENTA'TION. } fer: a sustainer is one who endures; sustenance and sustentation, both mean support; maintenance; necessaries of life; support of life.

There are unto one end sundry means: as for the *sustenance* of our bodies many kinds of food, many sorts of raiment to clothe our nakedness.

Hooker.

If you omit

The offer of this time, I cannot promise
 But that you shall *sustain* more new disgraces,
 With these you bear already.

Shakspeare. Henry VIII.

They charged, on pain of perpetual displeasure, neither to entreat for him, or any way *sustain* him.

Shakspeare.

When there be great shoals of people, which go on to populate, without foreseeing means of life and *sustentation*; it is of necessity that once in an age they discharge a portion of their people upon other nations.

Bacon.

But it on her, not she on it depends;
 For she the body doth *sustain* and cherish.

Davies.

Thyself hast a *sustainer* been
 Of much affliction in my cause. *Chapman's Iliad.*
 My labour will *sustain* me. *Milton.*

Were it I thought death menaced would ensue
 This my attempt, I would *sustain* alone
 The worst, and not persuade thee.

Id.

A very abstemious animal, by reason of its frugidity and latiancy in the winter, will long subsist without a visible *sustentation*.

Browne's Vulgar Errors.

Scarcely allowing himself fit *sustenance* of life, rather than he would spend those goods for whose sake only he seemed to joy in life.

Sidney.

Sacharissa's beauty's wine
 Which to madness doth incline;
 Such a liquor as no brain
 That is mortal can *sustain*.

Waller.

These streams, once raised above the earth, have their ascent and *sustentation* aloft promoted by the air.

Boyle.

If he have no comfortable expectations of another life to *sustain* him under the evils in this world, he is of all creatures the most miserable.

Tillotson.

The admirable curiosity and singular excellency of this design will *sustain* the patience, and animate the industry, of him who shall undertake it.

Holder.

The ancients were inventors of all arts necessary to life and *sustenance*, as plowing and sowing.

Temple.

Vain is the force of man,
 To crush the pillars that the pile *sustain*.

Dryden's Æneid.

His sons, who seek the tyrant to *sustain*,
 And long for arbitrary laws again,
 He dooms to death, asserting public right. *Id.*
 Can Ceyx then *sustain* to leave his wife,
 And unconcerned forsake the sweets of life?

Dryden.

The experiment cost him his life for want of *sustenance*.

L'Estrange.

Is then the honour of your daughter of greater moment to her than to my daughter her's whose *sustenance* it was?

Addison.

The mind stands collected within herself, and *sustains* the shock with all the force which is natural to her; but a heart in love has its foundations sapped.

Id.

The largeness and lightness of her wings and tail *sustain* her without lassitude.

More.

SUTE, *n. s.* For Suite. Sort. Perhaps only misprinted.

Touching matters belonging to the church of Christ, this we conceive, that they are not of one *sute*.

Hooker.

SUTHERLAND-SHIRE, one of the most northerly counties of Scotland, extending the whole breadth of the island; about eighty miles in length, from north-west to south-east, and forty miles in breadth, containing 1800 square miles, or 1,122,560 acres; of which forty-seven square acres are water. It is bounded on the north-east by Caithness, on the east and south-east by the German Ocean and the Frith of Dornoch, on the south and south-west by Ross-shire, on the west by the Atlantic Ocean, and on the north by the North Sea.

This county comprehends the districts of Strathnaver, Assint, and Sutherland. The face of the country is mountainous and rocky; partly covered with forests, and part being bleak and barren heaths. The valleys are occupied by numerous lakes and rivers, the chief of which are Loch-Shin, Loch-Naver, Loch-Lyol; and the rivers Oikel, Helmdale, Shin, Naver, Strathy, Brora, &c. The coasts, for the most part, on the north and west, are bold and rocky, indented by numerous bays of great extent. The principal arms of the sea are, Lochs Eribole, Durness, Laxford, Inchaid, and Lowie; and the chief promontories are, Cape Wrath, Far-out-head, Whiten-head, and Strathy-head. Many small islands are scattered along the coast, but few of which are inhabited. It possesses several commodious harbours and fishing-stations, chiefly at the mouth of the rivers. The principal crops raised in Sutherland are oats, and bear alternately, with a few potatoes. The climate is temperate, especially on the east coast; towards Assint and the north-west it is rather cold and damp, from its vicinity to the sea, and is subject to frequent storms. Here are three great deer forests. The people of Sutherland are hardy, and make excellent soldiers; and, for the most part, speak the language of the Lowlanders. Sutherland-shire contains only one town; viz. Dornoch, which is the county town; and several small fishing villages. It is divided into thirteen parochial districts, which contain 23,840 inhabitants. This county has abundance of free-stone, limestone, and slate; the lime-stone, in the parish of Assint, is of the nature of marble. Rock crystals and pebbles are found in many parts; and beautiful garnets are found on the coast, in the parish of Tongue. In no part of Scotland have greater changes and improvements taken place, within the last few years, than in this county; and this change has been accomplished by the forming of new roads, building new bridges, and removing the hardy natives from their moun-

tainous glens to the sea-coasts, and other situations better suited to advance their own interests, and to increase the prosperity of the country. So strongly, however, were the inhabitants attached to their ancient customs, and modes of living, that the change was not effected but by the adoption of the most decisive measures, on the part of the land proprietors, and even their masters were opposed with a spirit, on the part of the mountaineers, which gave the fullest evidence of their reluctance to relinquish the habitations and pursuits of their ancestors. In 1820 the opposition to their removal totally subsided, and the hardy inhabitants are now establishing fisheries, and devoting themselves to agricultural improvements, in those situations which are best calculated to reconcile them to their new occupations, and to excite them, by their advantages, to habits of industry and perseverance. The county gives the title of earl to the Sutherland family. It sends one member to parliament.

SUTLER, *n. s.* Belg. *soeteler*; Germ. *sudler*. A man that sells provisions and liquor in a camp.

I shall *sutler* be

Unto the camp, and profits will accrue.

Shakspeare. Henry V.

Send to the *sutler's*, there you're sure to find
The bullly matched with rascals of his kind.

Dryden.

SUTTON (Thomas), esq., founder of the Charter-house, was born at Knaith in Lincolnshire, in 1532, of an ancient and genteel family. He was educated at Eton, and Cambridge, and studied the law in Lincoln's-Inn; but preferred travelling, and during his absence his father died, and left him a large fortune. On his return he became secretary to the earl of Warwick, and his brother the earl of Leicester. By the former, in 1569, he was appointed master of the ordnance at Berwick; and, distinguishing himself greatly on the rebellion which broke out in the north, he obtained a patent for that office for life. He was one of the chiefs of those 1500 men who marched into Scotland, by order of queen Elizabeth, to assist the regent, Morton, in 1573. He purchased the manors of Gatheshead and Wickham; which, producing coal mines, became to him a source of extraordinary wealth. Soon after this he married a rich widow, who brought him a considerable estate; and, commencing merchant, riches flowed in to him. He was likewise a commissioner for prizes, and took a Spanish ship worth £20,000. His whole fortune, at his death, was, in land, £5000 a year; in money above £60,000; the greatest estate then in the possession of any private gentleman. He lived with great munificence and hospitality; but, losing his lady in 1602, he retired from the world, and, having no issue, he purchased of the earl of Suffolk Howard House, or the Charter-house, near Smithfield, for £13,000, where he founded the present hospital, in 1611, for the relief of poor men and children. He died December 11th, 1611, at Hackney, aged seventy-nine. His body was conveyed to Christ-church, and there deposited, till 1614, when it was removed to the charter-house, and interred in the chapel under a magnificent tomb.

SUTTON (Samuel), was born at Alfreton in

Derbyshire, and going into the army served under the duke of Marlborough in queen Anne's wars with great credit. He afterwards came to London, commenced brewer, and kept a coffee-house in Aldersgate Street, which was well frequented by the learned men of that time, by whom Mr. Sutton was much respected as a man of strong natural parts and cultivated genius. About 1740 he schemed a very simple and natural method for extracting the foul air from the wells of ships, by pipes communicating with the fire-places of the coppers; which operated as long as any fire was kept burning for the ship's use. He took out a patent in 1744, to secure the profits of his invention; and died in 1752.

SUTTON-COLEFIELD, a market-town in Hemlingford hundred, Warwick. One mile from Warwick, and 110 from London. The parish is very extensive, but the town is situate in a very bleak and barren tract of land. It has a good church, with a square tower, containing six bells. Here is a free grammar-school, which, with other very considerable advantages to the town and the poor, was founded by Vesey, bishop of Exeter, in the reign of Henry VIII. The Birmingham trade has been introduced here. The town is governed by a warden and ten aldermen. Its chase (the remains of a forest) is an extensive tract. Market on Monday. Fairs, Trinity-Monday, and November 8th.

SUTTULEGE, SETLEGE, or SUDLEGE, a celebrated river of Hindostan, the easternmost of the five which are called the Punjab. It rises in the Himalaya mountains, and, running to the south-west, is joined by the Beyah or Hlyphasis, in the lat. of 30° N. The united streams fall into the Indus, near 29°. It is estimated to be about 600 miles in length, and to be navigable by large boats for 200 miles above its junction with the Indus.

SUTURE, *n. s.* Lat. *sutura*. A manner of sewing or stitching wounds. See below.

Wounds, if held in close contact for some time, unite by insolation: to maintain this situation, several sorts of *sutures* have been invented: those now chiefly described are the interrupted, the glovers, the quilled, the twisted, and the dry *sutures*; but the interrupted and twisted are almost the only useful ones.

Sharp's Surgery.

Many of our vessels degenerate into ligaments, and the *sutures* of the skull are abolished in old age.

Arbuthnot.

SUTURE, in anatomy. See ANATOMY.

SUTURE, in surgery. See SURGERY.

SUVARROF, SUWARROW, or SUWOROW (Alexander, count Rymnikski), a late eminent general in the Russian service. His family was ancient and respectable; but being far from affluent, and their property lying at the extremity of the empire, the subject of this memoir was the first of the family that ever was at court. He was born in 1730. His father had destined him for the law, but his inclination led him to the profession of a soldier; and in 1742 he was enrolled as a fusilier in the guards of Seimonow. He was afterwards a corporal, then a serjeant, and in 1754 he quitted the guards with the brevet of lieutenant in the army. He made his first campaign in the seven years war against the

Prussians, in 1759, entering upon actual service under prince Wolgonski. In 1761 he was ordered on service in the light troops under general Berg; and with the rank of a lieutenant colonel he performed prodigies of valor. At the peace of 1762 he received from the empress a colonel's commission, written with her own hand; and being advanced, in 1768, to the rank of brigadier, he was, in November, ordered to repair to the frontiers of Poland. The object of the empress, at this time, was to subdue the Polish confederates, and to possess herself of certain provinces of that ill-fated kingdom. How completely she and her two allies, the emperor of Germany and the king of Prussia, succeeded in their enterprise, has been related under POLAND. Here we need only observe that the successes of the Russians were chiefly owing to the military skill of Suworow. In 1770 he had been promoted to the rank of major-general; and, for his exploits in the Polish war, the empress conferred upon him, at different times, the orders of St. Anne, St. George, and Alexander Newsky. After performing some important services on the frontiers of Sweden, Suworow was ordered, in 1773, to join the army in Moldavia, under field-marshal Romanzow; and there he began that successful career which soon made his name a terror to the Turks. His first exploit was the taking of Turtukey. During the remainder of the war, which was short, Suworow was constantly engaged, and constantly successful. Early in 1774, he was promoted to the rank of lieutenant-general, and on the 11th of June he defeated the Turks in a great battle. Soon after this victory, peace was concluded, and Suworow was called to Moscow to quell the rebellion of the Cossac Pugatscheff. For several years after Suworow was employed in the Crimea, on the Kuban, and against the Nogay Tartars, in a service, which, though it was of the utmost importance to the empress, and required all his address, furnished no opportunities for that wonderful promptitude and resource which had characterised his more active campaigns. In the end of 1786, Suworow was promoted to the rank of general-in-chief; and, at the breaking out of the war with the Turks in 1787, he made a most masterly defence of Kinburn; a place of little strength, but great importance, as it is situated at the mouth of the Dnieper, opposite to Oczakow. For his zeal and abilities, on this occasion, the empress honored him with the order of St. Andrew. At the siege of Oczakow, Suworow, who commanded the left wing of the army under prince Potemkin, received a dangerous wound in the neck, which was followed by so smart a fever, that, for some time his life was despaired of; but, preferring regimen to medicine, his health was gradually re-established. In 1789 he was appointed to command the army which was to cooperate with the prince of Saxe-Coburg in Wallachia; and, by marches of inconceivable rapidity, he twice, in two months, preserved the army of that prince from destruction. Putting himself at the head of 8000 Russians, and literally running to the aid of his ally, he came up with the Turks in time to change the fate of the day at the battle of Forhani, which was fought on the 21st

of July; and again at Rymnik, which with 7000 men he had reached with equal celerity, he gained, on the 22d of September, in conjunction with the prince, one of the greatest victories that have ever been achieved. No quarter was given to the Turks; and on this account the Russian general has been charged with savage ferocity. The taking of Bender and Belgrade were the immediate consequences of the victory of Rymnik; and so sensible was the emperor Joseph II. how much the military skill of Suworow had contributed to that victory, that he created him a count of the Roman empire, and accompanied the diploma with a very flattering letter. Similar honors were conferred upon him by Catherine II., who sent him the diploma of count of the empire of Russia, with the title of Rymnikski, and the order of St. Andrew. In autumn 1790 he took Ismailow, after being defended by the Turks at an expense of 33,000 men killed or dangerously wounded; 10,000 taken prisoners; besides 6000 women and children, and 2000 Christians of Moldavia, who fell in one general massacre. Peace being concluded with the Turks, in December 1791, no events occurred from that period to call forth the talents of Suworow till 1794; when mutinies having broken out among the Polish troops in the service of Russia, and the empress with her two allies having resolved on the second partition of Poland, Suworow received orders, in May, to proceed into Red Russia, with a corps of 15,000 men, and to disarm all the Polish troops in that province. This service he soon performed, disarming in less than a fortnight 8000 men, dispersed over a country of 130 miles in circuit. Soon afterwards he was ordered to march into Poland; the king of Prussia having raised the siege of Warsaw, and the empress perceiving that more vigorous measures were necessary to accomplish her design. Under the article POLAND we have given a detailed account of his route to Warsaw. Suffice it to add that he in the course of a very few months overturned the kingdom and republic of Poland. For this service Catherine promoted him to the rank of field-marshal general, loading him with jewels and presenting him with an estate of 7000 peasants in the district of Kubin, which had been the scene of his first battle in the campaign. From the subjugation of Poland we hear little more of Suworow till he entered upon his great career in Italy. For his services in this part of Europe Paul rewarded him by creating him a prince by the title of prince Suworow Italiski; but he gave him a very different reception when he returned into the Russian dominions at the head of his veteran bands. He would not see him, and positively forbid his appearance at court. To the messenger who brought the order, he gave a purse of money, turned his carriage another way, and drove to a wooden house at a distance from the court, and from his former friends, where the conqueror of the Turks, the Poles, and the French republicans, died, almost unattended, on the 18th of May, 1800. The sovereign, who thus disgraced him at the end of his life, gave him a magnificent funeral! In his person Suworow was tall, considerably exceed-

ing six feet, and full chested. His countenance was stern; but among his friends his manners were pleasant, and his dispositions were kind. His temper was naturally violent; but that violence he labored much to moderate, though he was never able completely to extinguish it. He was a scholar, a man of science, and a poet. In 1774 he married a daughter of the general prince John Proszowski, by whom he had two children, now living; Natalia, married to general count Nicolas Zubow; and Arcadius count Suworow, a youth of promising abilities, who accompanied his father in his march from Italy into Switzerland.

SUZE (Henriette de Coligni), countess of, daughter of the celebrated marshal De Coligni, a French lady, eminent for her poetical abilities. She married first Thomas Hamilton, a Scottish nobleman, and after his death the count La Suze, who was also of an illustrious family. But this second marriage proved unhappy, and ended in a separation. She wrote a great number of Poems, which were much admired; and were collected and printed with those of Pellisson and madam Scudery, at Trevous, in 1725, 12mo. She died in 1673.

SWAB, *v. a.* } Sax. *ƿeabban*. Belg. *swab-*
SWAB'BER, *n. s.* } *ber*. To clean with a mop: a sweeper of the deck. Used chiefly at sea.

The master, the *swabber*, the boatswain and I, Loved Moll, Meg, and Marian, and Margery.

Shakspeare.

Was any thing wanting to the extravagance of this degenerate age, but the making a tarpawlin and a *swabber* the hero of a tragedy?

Dennis.

He made him *swab* the deck. *Shelvoek's Voyage.*

SWABIA. See SUABIA.

SWAD'DLE, *v. a.* & *n. s.*,

SWAD'DLINGBANDS, *n. s.* } Saxon *ƿe-*
SWAD'DLINGCLOTH, } *ban*. To swathe;
SWAD'DLINGCLOUT. } bind in clothes, generally used

of binding new-born children: the noun substantives the band or cloth used.

Invested by a veil of clouds,

And *swaddled* as new-born in sable shrouds;

For these a receptacle I designed. *Sandys.*

From thence a fairy thee unweeting reft,

There as thou slep'st in tender *swaddlingband*,

And her base elfin brood there for thee left;

Such men do changlings call, so changed by fairies theft. *Spenser.*

That great baby you see there is not yet out of his *swaddling-clouts*. *Shakspeare. Hamlet.*

How soon doth man decay!

When cloths are taken from a chest of sweets,

To *swaddle* infants, whose young breath

Scarce knows the way;

Those clouts are little winding sheets,

Which do consign and send unto death. *Herbert.*

Great on the bench, great in the saddle,

That could as well bind o'er as *swaddle*. *Hudibras.*

The *swaddlingbands* were purple, wrought with gold. *Dryden.*

I begged them to uncase me; no, no, say they; and upon that carried me to one of their houses, and put me to bed in all my *swaddles*. *Addison.*

They *swaddled* me up in my night-gown with long pieces of linen, till they had wrapt me in about a hundred yards of swathe. *Id.*

SWAFFHAM, a market-town in South-Greenhoe hundred, Norfolk, fifteen miles south-east of

Lynn, and ninety-three N. N. E. from London. The church is a handsome building, in the form of a cathedral. The vaults and aisles are supported by light pillars, forming fourteen handsome arches, seven on a side, over which there are twenty-eight neat, light windows. Here is a quakers' meeting-house. On a heath near the town, horse-races are held. On the market-hill a handsome cross has been erected by the earl of Orford, and on the west side of the hill a subscription assembly-room has been built. Its noted butter-market was originally held at Debeh-am. Market on Saturday. Fairs, May 13th, July 21st, and November 3rd. It is a vicarage, value £14 8s. 10d. Patron, the bishop of Norwich.

SWAG, *v. n.* } Sax. *ƿigan*; Isl. *swelgia*. To
SWAG'G, *adj.* } sink down by its weight; hang heavy: the adjective corresponding.

They are more apt, in *swagging* down, to pierce with their points, than in the jacent posture, and crevice the wall. *Wotton.*

The beaver is called animal ventricosum, from his *swaggy* and prominent belly.

Brown's Vulgar Errors.

Being a tall fish, and with his sides much compressed, he hath a long fin upon his back, and another answering to it on his belly; by which he is the better kept upright, or from *swagging* on his sides. *Grew.*

SWAGE, *v. a.* From asswage. To ease; to soften; to mitigate.

Nor wanting power to mitigate and *swage*, With solemn touches, troubled thoughts, and chase Anguish, and doubt, and fear from mortal minds. *Milton.*

I'd find some intervals when my poor heart Should *swage* itself, and be let loose to thine. *Otway.*

SWAG'GER, *v. n.* } Sax. *ƿægan*; Belgic
SWAG'GERER, *n. s.* } *swadderen*. To bluster; bully; be turbulently proud and insolent: the noun substantive corresponding.

Drunk? squabble? *swagger*? and discourse sustain with one's own shadow? Oh thou invincible spirit of wine! *Shakspeare.*

He's no *swaggerer*, hostess; a tame cheater: you may stroke him as gently as a puppy greyhound. *Id. Henry IV.*

The lesser size of mortals love to *swagger* for opinions, and to boast infallibility of knowledge. *Glanville's Scepis.*

Confidence, how weakly soever founded, hath some effect upon the ignorant, who think there is something more than ordinary in a *swaggering* man, that talks of nothing but demonstration. *Tillotson.*

He chucked,

And scarcely deigned to set a foot to ground, But *swaggered* like a lord. *Dryden.*

Many such asses in the world huff, look big, stare, dress, cock, and *swagger* at the same noisy rate. *L'Estrange.*

To be great is not to be starched, and formal, and supercilious; to *swagger* at our footmen and brow-beat our inferiours. *Collier on Pride.*

What a pleasure is it to be victorious in a cause: to *swagger* at the bar! for a lawyer I was born, and a lawyer I will be. *Arbuthnot's History of John Bull.*

SWAIN, *n. s.* Sax. and Runic *ƿæin*; Goth. *swcina*. A young man; country servant or youth; a lover.

That good knight would not so nigh repair,
Himself estranging from their joyance vain,
Whose fellowship seemed far unfit for warlike swain.
Spenser.

It were a happy life
To be no better than a homely swain.
Shakspeare. Henry VI.

Blest swains! whose nymphs in every grace excel;
Blest nymphs! whose swains those graces sing so
well.
Pope.

Leave the mere country to mere country swains,
And dwell where life in all life's glory reigns.
Harte.

SWAL'LOW, *v. a. & n. s.* Sax. *swelgan*; Belg. *swelgen*; Goth. and Swed. *swelgia*. To take down the throat: hence to absorb; receive without examination; seize; engross; waste: as a noun substantive, a throat; voracity.

If the earth open her mouth and swallow them up, ye shall understand that these men have provoked the Lord.
Numbers xvi.

Far be it from me that I should swallow up or destroy.
2 Samuel.

Death is swallowed up in victory. *1 Cor. xv. 54.*
The priest and the prophet are swallowed up of wine.
Isaiah.

If little faults
Shall not be winked at, how shall we stretch our eye,
Whose capital crimes chewed, swallowed, and digested,

Appear before us? *Shakspeare. Henry V.*

Though you unite the winds, and let them fight,
Against the churches, though the yesty waves
Confound and swallow navigation up. *Shakspeare.*

I may be plucked into the swallowing womb
Of this deep pit, poor Bassianus' grave:

Id. Titus Andronicus.
He hid many things from us, not that they would swallow up our understanding, but divert our attention from what is more important. *Decay of Piety.*
In bogs swallowed up and lost. *Milton.*

Nature would abhor
To be forced back again upon herself,
And, like a whirlpool, swallow her own streams.
Dryden.

Men are, at a venture, of the religion of the country; and must therefore swallow down opinions, as silly people do emperic pills, and have nothing to do but believe that they will do the cure. *Locke.*

Consider and judge of it as a matter of reason, and not swallow it without examination as a matter of faith. *Id.*

The necessary provision for life swallows the greatest part of their time. *Id.*

Had this man of merit and mortification been called to account for his ungodly swallow, in gorging down the estates of helpless widows and orphans, he would have told them that it was all for charitable uses. *South.*

Should not the sad occasion swallow up
My other cares, and draw them all into it?
Addison.

Homer excels all the inventors of other arts in this, that he has swallowed up the honour of those who succeeded him. *Pope.*

Corruption swallowed what the liberal hand
Of bounty scattered. *Thomson's Autumn.*

SWAL'LOW, *n. s.* Sax. *swalpepe*. A small bird of passage. See below.

The swallow follows not summer more willingly than we your lordship. *Shakspeare. Timon.*

The swallows make use of celendine, and the linnet of euphrasia. *Aore.*

When swallows fleet soar high and sport in air,
He told us that the welkin would be clear. *Gay.*

SWALLOW, in ornithology. See *HIRUNDO*. Concerning these birds, a question has oft been discussed, What becomes of them in winter? Upon this subject there are three opinions. Some say that they migrate to a warmer climate; some that they retire to hollow trees and caverns, where they lie in a torpid state; and others affirm that they lie in the same state in the bottom of lakes and under the ice. The first opinion is supported by Marsigli, Ray, Willoughby, Catesby, Reaumur, Adanson, Buffon, &c. The first and second opinions are both adopted by Pennant and White. The third is sanctioned by Schæffer, Hevelius, Derham, Klein, Ellis, Linné, Kalm: and the second and third have been strongly defended by the honorable Daines Barrington. Those who assert that swallows migrate to a warmer country in winter, argue, That many birds migrate is a fact fully proved by the observations of natural historians. See *MIGRATION*. Is it not more probable, therefore, that swallows, which disappear regularly every season, retire to some other country, than that they lie in a state of torpor in caverns or lakes? But this opinion is founded on facts. We often see them collected in great flocks on churches, rocks, and trees, about the time when they annually disappear. The direction of their flight has been observed to be to the southward. Mr. White, the ingenious historian of Selborne, travelling near the coast of the British Channel one morning early, saw a flock of swallows take their departure, with an easy and placid flight towards the sea. Mr. Laskey of Exeter observed the direction which a flock of swallows took in autumn 1793. On the 22d of September, about 7 A. M., the wind being easterly, accompanied with a cold drizzling rain, Mr. Laskey's house was entirely covered with house swallows. At intervals large flocks arrived and joined the main body, and at their arrival an unusual chirping commenced. The appearance of the whole company was so lethargic that he found it an easy matter to catch a considerable number of them, which he kept in a room all that day. By heating the room they all revived; he opened four of them, and found their stomachs quite full. The main body occupied the house top all day, except for two hours. About half an hour after 9 A. M. the 23d, there was a great commotion, with very loud chirping, and, within a few minutes after, the whole multitude took their flight, in a south-east direction, having ascended to a great height in the atmosphere. He let go the birds which he had caught, at certain intervals till four o'clock, and they all fled toward the same quarter. They have also been found on their passage at a great distance from land. Mr. Adanson informs us, that about fifty leagues from the coast of Senegal four swallows settled upon the ship on the 6th of October; that these birds were taken; and that he knew them to be European swallows, which, he conjectures, were returning to the coast of Africa. Sir Charles Wager, says, 'Returning home, in spring, as I came into soundings in our channel, a great flock of swallows came and settled on all my rigging; every rope

was covered; they hung on one another like a swarm of bees; the decks and carving were filled with them. They seemed almost famished and spent, and were only feathers and bones; but, being recruited with a night's rest, took their flight in the morning.' This vast fatigue proves that their journey must have been very great, considering their amazing swiftness; in all probability they had crossed the Atlantic Ocean, and were returning from the shores of Senegal, or other parts of Africa; so that this account, from that most able and honest seaman, confirms the latter information of Mr. Adanson. Mr. Bruce also mentions, in his travels, that in Abyssinia there is a great variety of swallows; but 'those that are common in Europe appear in passage at the very season when they take their flight thence. We saw the greatest part of them in the island of Masuah, where they lighted and tarried two days, and then proceeded with moonlight, to the south-west.' Mr. Kalm acknowledges that in crossing the Atlantic, from Europe, a swallow lighted on the ship on the 2d of September, when it had passed only two-thirds of the ocean. Since, therefore, swallows have been seen assembled in great flocks in autumn, flying off in company towards southern climes, since they have been found both in their passage from Europe and returning again, can there be any doubt of their annual migration? The second notion (says Mr. Pennant) has great antiquity on its side. Aristotle and Pliny say that swallows do not remove very far from their summer habitation, but winter in the hollows of rocks, and during that time lose their feathers. Of late several proofs have been brought of some species having been discovered in a torpid state. Mr. Collinson mentions three gentlemen, eye-witnesses to numbers of sand martins being drawn out of a cliff on the Rhine, in March 1762. And the honourable Daines Barrington communicated the following fact, on the authority of the late Lord Belhaven:—That numbers of swallows have been found in old dry walls and in sand hills near his lordship's seat in East Lothian, from year to year; and that when they were exposed to the warmth of a fire they revived. We have heard of the same annual discoveries near Morpeth, in Northumberland. Others prove the residence of those birds in a torpid state during winter. 1. In the chalky cliffs of Sussex; as was seen on the fall of a great fragment some years ago. 2. In a decayed hollow tree that was cut down, near Dolgelli, in Merionethshire. 3. In a cliff, near Whitby, Yorkshire; where, on digging out a fox, whole bushels of swallows were found in a torpid condition. 4. The Rev. Mr. Conway of Sychton, Flintshire, a few years ago, on looking down an old lead mine in that county, observed numbers of swallows clinging to the timbers of the shaft, seemingly asleep; and on flinging some gravel on them they just moved, but never attempted to fly: this was between All Saints and Christmas. From all these facts, we must conclude that one part of the swallow tribe migrate, and that others have their winter quarters near home. The third opinion is that of Mr. Kalm, who pleads for their immersion in water; and mentions the following

facts:—'Dr. Wallerius, the celebrated Swedisch chemist, informs us that he has seen, more than once, swallows assembling on a reed till they were all immersed and went to the bottom; this being preceded by a didge of a quarter of an hour's length. He had seen a swallow caught during winter out of a lake with a net, drawn, as is common in northern countries, under the ice; this bird was brought into a warm room, revived, fluttered about, and soon after died. Mr. Klein applied to many farmers general of the king of Prussia's domains, who had great lakes in their districts, the fishery in them being a part of the revenue. All the people that were questioned made affidavits upon oath before the magistrates. 1. The mother of the countess of Lehdorf said that she had seen a bundle of swallows brought from the Frische-Hoff (a lake communicating with the Baltic at Pislau), which, when brought into a moderately warm room, revived and fluttered about. 2. Count Schiteben gave an instrument on stamped paper, importing that by fishing on the lake belonging to his estate of Gerdauden in winter, he saw several swallows caught in the net, one of which he took up in his hand, brought it into a warm room, where it lay about an hour, when it began to stir, and half an hour after it flew about in the room.' Mr. Kalm mentions similar affidavits made by four farmers; and at last adds, '7thly, I can reckon myself,' says our author, 'among the eye-witnesses of this paradox of natural history. In 1735, being a boy, I saw several swallows brought in winter by the fishermen from the Vistula to my father's house; where two of them were brought into a warm room, revived and flew about. I saw them several times settling on the warm stove, and I recollect well that the same forenoon they died, and I had them, when dead, in my hand. In January 1754, being covered with ice, I ordered the fishermen to fish therein, and, in my presence several swallows were taken, which the fishermen threw in again; but one I took up myself, brought it home, five miles from thence, and it revived, but died about an hour after.' These are facts attested by people of the highest quality. It is therefore incontestably true, that swallows retire in the northern countries, during winter, into the water, and stay there in a torpid state till the return of warmth revives them again in spring. The swallows in Spain, Italy, France, and perhaps some from England, remove to warmer climates; some English ones, and some in Germany and other mild countries, retire into elefs and holes in rocks, and remain there in a torpid state. In the colder northern counties the swallows immerse in the sea, in lakes, and rivers; and remain in a torpid state, under ice, during winter. It is objected, Why do not rapacious fish, and aquatic quadrupeds and birds, devour these swallows? The answer is obvious: swallows choose only such places in the water for their winter retreat as are near reeds and rushes; so that sinking down there between them and their roots they are secured against their enemies. As to the argument taken from their being so long under water without corruption, there is a real difference between animals suffocated in water and animals

being torpid therein. Natural history ought to be studied as a collection of facts. There are five species of swallows which visit Britain during summer; the common swallow, the martin, sand martin, swift, and goat-sucker. 1. The common swallow frequents almost every part of the old continent; being known, says Dr. Latham, from Norway to the Cape of Good Hope on the one side, and from Kamtschatka to India and Japan on the other. It is also found in all parts of North America, and in several West Indian islands. In Europe it disappears during winter. It appears generally a little after the vernal equinox; but rather earlier in the southern, and later in the northern latitudes. It adheres to the usual seasons with much regularity. In the warm spring of 1774 they appeared no earlier than usual. They remain in some warm countries the whole year. Kolben assures us that this is the case at the Cape of Good Hope. Some birds of this species live, during winter, even in Europe; e. g. on the coast of Genoa. 2. The martins are widely diffused through the old continent. 3. The sand martins are found in every part of Europe, and often spend the winter in Malta. 4. The swift visits the whole continent of Europe; has also been observed at the Cape of Good Hope, and in Carolina in North America. 5. The goat suckers are not very common, yet are found in every country between Sweden and Africa: also in India. Mr. Markwick of Catsfield, near Battle in Sussex, has drawn up an accurate table, expressing the day of the month on which the migratory birds appeared in spring, and disappeared in autumn, for sixteen years, from 1766 to 1783 at Catsfield. Were tables of the same kind made in every different country, particularly within the torrid zone, it would be easy to determine the question which we have been considering. To many, perhaps, it may not appear of so much importance as to be worth the labor. But the enquiry must be highly gratifying to every mind that admires the wisdom of the Great Architect of nature. The instinct of the swallow is indeed wonderful: it appears among us just at the time when insects become numerous: and it continues with us during the hot weather, to prevent them from multiplying too much. It disappears when these insects are no longer troublesome. It is never found in solitude; it is the friend of man, and always takes up its residence with us, to protect us from being annoyed with swarms of insects.

SWALLOW HARBOUR, a convenient harbour on the shore of Terra del Fuego. There are two channels into it, which are both narrow, but not dangerous, as the rocks are easily discovered by their weeds. It is surrounded by steep mountains, covered with snow, which have a most horrid appearance, and seem to be altogether deserted. Long. 74° 30' W., lat. 53° 40' S.

SWALLOW ISLAND, one of the Queen Charlotte's Islands, of the South Pacific, about six leagues in length. Long. 165° 58' E., lat. 10° 8' S.

SWALLOWTAIL, *n. s.* Swallow and tail. A species of willow.

The shining willow they call *swallowtail*, because of the pleasure of the leaf.

Bacon's Natural History.

SWAMMERDAM (John), a celebrated natural philosopher, was the son of John James Swammerdam, an apothecary and famous naturalist of Amsterdam, and born in 1637. His father intended him for the church, and with this view had him instructed in Latin and Greek; but he preferred physic. Being kept at home till he should engage in that study, he was often employed in cleaning his father's curiosities, and putting every thing in order. This inspired him with an early taste for natural history; so that he soon began to make a collection of his own. When grown up, he attended to his anatomical and medical studies; but spent part of the day and the night in discovering, catching, and examining the flying insects of Holland, Guelderland, and Utrecht. Thus initiated in natural history, he went to the university of Leyden in 1651; and in 1663 was admitted a candidate of physic. While studying anatomy he considered how the parts of the body, prepared by dissection, could be preserved for anatomical demonstration; and he succeeded, as he had done before in his nice contrivances for dissecting the minutest insects. He then went to France, where he spent some time at Saumer, and became acquainted with several learned men. In 1667 he returned to Leyden, and took his degree of M. D. In 1668 the grand duke of Tuscany, being in Holland, came to view the museum of our author and his father; and Swammerdam made some anatomical dissections of insects in his presence. He was struck with admiration at his great skill in managing them; and proving that the future butterfly lay with all its parts neatly folded up in a caterpillar, by removing the integuments, and exhibiting all its parts, however minute, with incredible ingenuity by instruments of inconceivable fineness. The duke offered him 12,000 florins for his collection, on condition of his removing them into Tuscany, and residing at the court of Florence; but Swammerdam declined. In 1663 he published a General History of Insects. About this time his father, offended at his neglecting the practice of physic, would neither supply him with money nor clothes. This reduced him to some difficulties. In 1675 he published his History of the Ephemeras; and his father dying, in 1676, left him a fortune; but he died in 1682, aged only forty-five. Gadius translated all his works from the Dutch into Latin, from which they were translated into English, in folio, in 1748. See ENTOMOLOGY. Boerhaave wrote his life.

SWAMP, *n. s.* } Sax. *ƿamp*; Goth. and
SWAM'PY, *adj.* } Swed. *suamp*; Isl. *suamm*;
 Dan. *suomp*. A marsh; bog; fen; boggy; fenny.

Swampy fens breathe destructive myriads.

Thomson.

SWAN, *n. s.* Sax. *ƿpan*; Dan. *suan*; Swed. *swan*; Belg. *swaen*. A large water-fowl. See the extract from Calmet.

With untainted eye

Compare her face with some that I shall show,
 And I will make thee think thy *swan* a crow.

Shakspeare.

Let musick sound while he doth make his choice;
 Then, if he lose, he makes a *swan*-like end. *Id.*

The fearful matrons raise a screaming cry,
 Old feeble men with fainter groans reply;
 A jarring sound results, and mingles in the sky,
 Like that of *swans* remurmuring to the floods.

Dryden.

SWAN. See **ANAS.** It is now ascertained, beyond the possibility of doubt, that there are black swans, of equal size and the same habitudes with the common white swans of this island. These fowls have been seen chiefly in New Holland; and captain Vancouver, when there, saw several of them in very stately attitudes, swimming on the water, and, when flying, discovering the under part of their wings and breast to be white. Black swans were likewise seen in New Holland by governor Phillips, captain White, and by a Dutch navigator, so long ago as in 1697. Governor Phillips describes the black swan as a very noble bird, larger than the common swan, and equally beautiful in form. Mr. White, indeed, says that its size is not quite equal to that of the European swan; but both agree with captain Vancouver, in mentioning some white feathers in its wings.

SWAN, SWEYN, SUENO, or SWENO, I., II., and III., three kings of Denmark. See **DENMARK** and **SWENO.**

SWAN RIVER; a British colony, on the western coast of New Holland, established in 1829. It is situated on Swan river, so called from the great number of black swans seen upon it, which empties into the ocean in lat. $32^{\circ} 16' S.$, lon. $115^{\circ} 40' E.$ Several settlements have been formed, and the soil is represented as fertile. Swan river was explored for nearly sixty miles from its mouth, by M. Bailly, mineralogist to the expedition of Baudin, who found it to flow over calcareous rocks, through a country covered with thick forests of gum trees. At the point where his examination ceased, the river was a third of a mile in width, with a slow current. A group of islands opposite the mouth of the river offer some roadsteads, with safe anchorage for large vessels. Chief town, Perth.

SWAN RIVER, a river of North America, which takes its rise in lake Etowwemahmeh, whence it passes through Swan Lake into the Little Winnipic. This latter is connected, by a considerable river, with the lake of Manitoba, which, by the river Dauphin, finally discharges its waters into lake Winnipic, the common reservoir for the waters of a great number of the adjacent rivers and lakes. All the country in the neighbourhood of this, and of Red Deer River, to the south branch of the Saskatchewan, abounds in beaver, moose deer, fallow deer, elks, bears, buffaloes, &c. The soil is good, and, wherever attempts have been made to raise the esculent plants, it has been found productive. On this river a fort is erected for the convenience of the fur trade.

SWAN RIVER, a river of North America, which falls into the Mississippi about forty miles from its source.

SWANPAN, or Chinese Abacus, an instrument for performing arithmetical operations, described by Du Halde, in his history of China. It is composed of a small board, crossed with ten or twelve parallel rods or wires, each strung

with ivory balls, which are so divided, by a partition in the middle, that two are on one side of it, and five on the other. The two on the upper part stand each for five units, and each of the five in the lower part for one. 'In joining and separating these balls, they reckon much as we do with counters; but, according to our author, more expeditiously than Europeans do even with figures.' This is hardly credible; but, if all the Chinese weights and measures be decimally divided, it is easy to conceive how computation may be made, by this instrument, very expeditiously.

SWANSEA, or SWANSEY, is a borough town within the liberty of Gower, Glamorganshire, South Wales, governed by a portreeve, recorder, twelve aldermen, two common attorneys or chamberlains, two serjeants at mace, and an unlimited number of burgesses, and, together with four other contributory boroughs, viz., Kenfig, Aberavon, Neath, and Loughor, by the provisions of the Reform Bill, returns a member to parliament. The town lies at the confluence of the river Tawe with the Bristol Channel, whence the Welsh name Abertawe. It stands near the centre of a beautiful bay, denominated after the town, and has a capacious harbour, enclosed from the sea by two piers on the eastern and western side of the entrance. In the neighbourhood are very numerous and extensive collieries of bituminous coal, which is consumed at the copper works and other manufactories, and shipped off in large quantities to Ireland, Cornwall, and Devon. A canal extends from the town for nearly eighteen miles up the vale of Tawe to Hen-nyodd in Breconshire, for the conveyance of stone coal, culm, iron ore, &c., which is in a very flourishing state, and has been productive of great benefit to the town. There are two extensive potteries within the borough, and eight large copper smelting works, all within three miles distance, from which about 8000 tons of copper are annually exported to London, Liverpool, &c. In 1768, 694 vessels sailed from this port, tonnage 30,621; in 1792 the number of vessels was 2,590, tonnage 134,264; and in 1819 the number of ships sailing out of the port was 2750, tonnage 175,629, exclusive of 140,280 crates of earthenware shipped foreign, and 3521 crates coast-wise. It has two markets, abundantly supplied, on Wednesday and Saturday, and is famed for ship-building. The castle, which was formerly very extensive, was erected by Henry Beaumont, earl of Warwick, in the reign of Henry I.; it is now part of the possession of the duke of Beaufort. The town also contains two churches, and twelve meeting-houses, belonging to Dissenters of various denominations. During the summer season the town is much frequented for sea-bathing. It is forty-two miles W. N. W. of Cardiff, and 206 west of London.

SWARD, n. s. Swed. *sward.* The skin of bacon; the surface of the ground.

Water, kept too long, loosens and softens the *sward*, makes it subject to rushes and coarse grass.

Note on Tussar.

To plant a vineyard in July, when the earth is very dry and combustible, plow up the *swarth* and burn it.

Mortimer.

The noon of night was past, and then the foe
Came dreadless o'er the level *swart*, that lies
Between the wood and the swift streaming Ouse.

A. Philips.

SWARM, *n. s. & v. n.* Sax. *rpeapm*; Belg. *swarm*; Swed. *swärm*. A great body or number of small animals, particularly those bees that migrate from the hive: to gather or rise in a body; be crowded or thronged.

These garrisons you have now planted throughout all Ireland, and every place *swarms* with soldiers.

Spenser.

From this *swarm* of fair advantages,
You griped the general sway into your hand.

Shakspeare.

The merciless Macdonel,
The multiplying villainies of nature
Do *swarm* upon. *Id. Macbeth.*
Her lower region *swarms* with all sort of fowl, her
rivers with fish, and her seas with whole shoals.

Howel.

What a multitude of thoughts at once
Awakened in me *swarm*, while I consider
What from within I feel myself, and hear
What from without comes often to my ears!

Milton.

Not so thick *swarmed* once the soil
Bedropped with blood of Gorgon.

Id. Paradise Lost.

Those days *swarmed* with fables, and from such
grounds took hints for fictions, poisoning the world
ever after.

Browne.

A *swarm* of bees that cut the liquid sky,
Upon the topmost branch in clouds alight.

Dryden's Æneid.

Then mounts the throne, high placed before the
shrine;

In crowds around the *swarming* people join. *Id.*
Swarmed on a rotten stick the bees I spied. *Gay.*

When bees hang in *swarming* time, they will
presently rise, if the weather hold.

Mortimer's Husbandry.

If we could number up those prodigious *swarms*
that had settled themselves in every part of it, they
would amount to more than can be found.

Addison on Italy.

This *swarm* of themes that settles on my pen,
Which I, like summer-flies, shake off again,
Let others sing

Young.

Life *swarms* with ills, the boldest are afraid,
Where then is safety for a tender maid?

Id.

SWART, *adj. & v. a.* } Sax. *rpeapt*; Goth.
SWARTH, *adj.* or } *swarts*. Black; darkly
SWARTHY. } brown; tawny; dark of
complexion: to blacken.

A nation strange, with visage *swart*,
And courage fierce, that all men did affray,
Through the world then *swarmed* in every part.

Spenser.

A man

Of *swarth* complexion, and of crabbed hue,
That him full of melancholy did shew.

Id.

Whereas I was black and *swart* before;
With those clear rays which she infused on me,
That beauty am I blest with, which you see.

Shakspeare. Henry VI.

Though in the torrid climates the common color is
black or *swarthy*, yet the natural colour of the tem-
perate climates is more transparent and beautiful.

Hale's Origin of Mankind.

No goblin, or *swart* fairy of the mine,
Hath hurtful power o'er true virginity.

Milton.

The heat of the sun may *swart* a living part, or
even black a dead or dissolving flesh.

Browne's Vulgar Errors

Set me where, on some pathless plain,
The *swarthy* Africans complain.

Rosecombon

Did they know Cato, our remotest kings
Would pour embattled multitudes about him;
Their *swarthy* hosts would darken all our plains,
Doubling the native horror of the war,
And making death more grim.

Addison.

SWASH, *v. n.* } To make a great clatter or
SWASHER, *n. s.* } noise: whence *swashbuck-*
ler: a swasher is, a swaggerer; a bully. Not in
use.

We'll have a *swashing* and a martial outside,
As many other mannish cowards have.
That do outface it with their semblances.

Shakspeare.

Draw, if you be men: Gregory, remember thy
swashing blow.

Id. Romeo and Juliet.

I have observed these three *swashers*; three such
antics do not amount to a man.

Id. Henry V.

SWATCH, *n. s.* Corrupted from *swath*. A
swathe. Not in use.

One spreadeth those bands so in order to lie,
As barlie in *swatches* may fill it thereby.

Tusser.

SWATH, or **SWATHE**, *n. s. & v. a.* Belgic
swade. A line of grass cut down by the mower;
a band or fillet; to bind.

With tossing and raking, and setting on cox,
Grasse, lately in *swathes*, is meat for an ox.

Tusser.

The strawy Greeks, ripe for his edge,
Fall down before him, like the mower's *swath*.

Shakspeare.

He had two sons; the eldest of them at three
years old,

I' th' *swathing* cloaths the other, from their nursery
Were stolen.

Id. Cymbeline.

Their children are never *swathed*, or bound about
with any thing, when they are first born; but are
put naked into the bed with their parents to lie.

Abbot's Description of the World.

Swathed in her lap the bold nurse bore him out,
With olive branches covered round about.

Dryden.

As soon as your grass is mown, if it lie thick in
the *swath*, neither air nor sun can pass freely through
it.

Mortimer.

An Indian comb, a stick whereof is cut into three
sharp and round teeth four inches long: the other
part is left for the handle, adorned with fine straws
laid along the sides, and lapped round about it in
several distinct *swaths*.

Grew.

Long pieces of linen they folded about me, till
they had wrapped me in above an hundred yards of
swathe.

Guardian.

Master's feet are *swathed* no longer,
If in the night too oft he kicks,

Or shews his loco-motive tricks.

Prior.

SWAY, *v. a., v. n., & n. s.* Teut. *schweben*;
Goth. *sweiga*. To poise; weigh; wield; govern;
direct: to hang heavy; be drawn by weight;
have weight; bear rule: as a noun substantive,
the sweep or swing of a weapon; weight; pre-
ponderation; power; rule.

An evil mind in authority doth not only follow
the *sway* of the desires already within it, but
frames to itself new desires not before thought of.

Sidney.

Glancing fire out of the iron played,
As sparkles from the anvil rise,
When heavy hammers on the wedge are *swayed*.

The example of sundry churches, for approbation
of one thing, doth *sway* much; but yet still as hav-
ing the force of an example only, and not of a law.

This sort had some fear that the filling up the
seats in the consistory with so great number of lay-
men, was but to please the minds of the people, to
the end they might think their own *sway* somewhat.

Heaven forgive them, that so much have *swayed*
Your majesty's good thoughts away from me.

The lady's mad: yet if 'twere so,
She could not *sway* her house, command her fol-
lowers.

With such a smooth, discreet, and stable bearing.

The mind I *sway* by, and the heart I bear,
Shall never sag with doubt, nor shake with fear.

Aged tyranny *sways* not as it hath power, but as
it is suffered.

Only retain
The name and all the' addition to a king;
The *sway*, revenue, execution of the host,
Beloved sons, be yours.

In these personal respects, the balance *sways* on
our part.

On Europe thence, and where Rome was to *sway*
The world.

A gentle nymph, not far from hence,
That with moist curb *sways* the smooth Severn stream,
Sabrina is her name.

Here thou shalt monarch reign;
There didst not: there let him still victor *sway*.

To strike with huge two-handed *sway*.

The only way t' improve our own,
By dealing faithfully with none;
As bowls run true by being made
On purpose false, and to be *swayed*.

Thy judgment is *swayed* by passion, and stored
with ludicrous opinions, instead of clearly con-
ceived truths.

When examining these matters, let not temporal
and little advantages *sway* you against a more du-
rable interest.

With these I went,
Nor idle stood with unassisting hands,
When savage beasts, and men's more savage bands,
Their virtuous toils subduing; yet those I *swayed*
With powerful speech: I spoke, and they obeyed.

Too truly Tamerlane's successors they;
Each thinks a world too little for his *sway*.

They rush along, the rattling woods give way,
The branches bend before their sweepy *sway*.

They will do their best to persuade the world that
no man acts upon principle, that all is *swayed* by
particular malice.

When vice prevails, and impious men bear *sway*,
The post of honour is a private station.

SWEAR, *v. n.* & *v. a.* } *Pret.* swore or
SWEARER, *n. s.* } *sware*; *part. pass.*
sworn. Sax. *ƿƿearan*; Gothic *swaran*; Belgic
sweren. To obtest some superior power; utter
an oath: declare or engage, or give evidence on

oath; to put to oath; to declare upon oath: the
noun substantive corresponding.

Jacob said, *Swear* to me; and he *swear* unto him.

Moses took the bones of Joseph; for he had strait-
ly *sworn* the children of Israel.

If a man vow a vow unto the Lord, or *swear* an
oath to bind his soul with a bond, he shall not break
his word.

Because of *swearing* the land mourneth.

We shall have old *swearing*
That they did give the rings away to men:
But we'll outface them, and outswear them too.

I would have kept my word;
But, when I *swear*, it is irrevocable.

At what ease
Might corrupt minds procure knaves as corrupt
To *swear* against you!

Obey thy parents, keep thy word justly;
Swear not.

Sworn ashore, man, like a duck; I can swim like
a duck, I'll be *sworn*.

Now, by Apollo, king, thou *swear'st* thy gods in
vain.

—O vassal! miscreant!
And must they all be hanged that *swear* and lie?

—Every one.
—Who must hang them?

—Why, the honest men.
—Then the liars and *swearers* are fools; for there
are liars and *swearers* enow to beat the honest men,
and hang them up.

Bacchus taken at Rhodes by Demetrius Poliorcetes,
which he so esteemed, that, as Plutarch reports, he
sware he had rather lose all his father's images than
that table.

Take not his name, who made thy mouth, in vain
It gets thee nothing, and hath no excuse:

Lust and wine plead a pleasure, avarice a gain;
But the cheap *swearer*, through his open sluice
Lets his soul run for naught.

Of all men a philosopher should be no *swearer*;
for an oath, which is the end of controversies in law,
cannot determine any here, where reason only must
induce.

None so nearly disposed to scoffing at religion as
those who have accustomed themselves to *swear* on
trifling occasions.

Let me *swear* you all to secrecy;
And, to conceal my shame, conceal my life.

Thee, thee an hundred languages shall claim,
And savage Indians *swear* by Anna's name.

It is the opinion of our most refined *swearers* that
the same oath or curse cannot, consistently with true
politeness, be repeated above nine times in the same
company by the same person.

Hark! the shrill notes transpierce the yielding air,
And teach the neighbouring echoes how to *swear*.

SWEAT, *n. s.*, *v. n.*, & *v. a.* Sax. *ƿƿear*; Belg.
swacet. The matter evacuated at the pores: of the
skin; hence labor; toil; drudgery: to exude,
or be moist with such matter; to toil; to drudge;
emit as sweat: the adjective corresponding.

This painful labour of abridging was not easy, but
a matter of *sweat* and watching.

Let them be free, marry them to your heirs,
Why *sweat* they under burthens?

Let them be free, marry them to your heirs,
Why *sweat* they under burthens?

Why *sweat* they under burthens?

Why *sweat* they under burthens?

Why *sweat* they under burthens?

Why *sweat* they under burthens?

Why *sweat* they under burthens?

Why *sweat* they under burthens?

Why *sweat* they under burthens?

Mistress Page at the door, *sweating* and blowing,
and looking wildly, would needs speak with you.

Shakspeare.

Grease that 's *sweaten*
From the murderer's gibbet, throw
Into the flame. *Id. Macbeth.*

The rabblement hooted and clapped their chopped
hands, and threw up their *sweaty* night caps.

Shakspeare. Julius Cæsar.

Sweat is salt in taste; for that part of the nourishment which is fresh and sweet turneth into blood and flesh; and the *sweat* is that part which is excreted. *Bacon.*

About this time in autumn there reigned in the city, and other parts of the kingdom, a disease then new; which, of the accidents and manner thereof they called the *sweating* sickness.

Id. Henry VII.

Wainscots will *sweat* so that they run with water.

Bacon.

A young tall squire
Did from the camp at first before him go;
At first he did, but scarce could follow straight,
Sweating beneath a shield's unruly weight. *Cowley.*

What from Jonson's oil and *sweat* did flow,
Or what more easy nature did bestow
On Shakspeare's gentler muse, in thee full grown
Their graces both appear. *Denham.*

The field

To labour calls us, now with *sweat* imposed.

Milton.

How the drudging goblin *sweat*
To earn his cream bowl duly set;
When in one night, ere glimpse of morn,
His shadowy flail hath threshed the corn. *Id.*

A *sweaty* reaper from his tillage brought
First-fruits, the green ear, and the yellow sheaf. *Id.*

Our author, not content to see
That others write as carelessly as he;
Though he pretends not to make things complete,
Yet, to please you, he'd have the poet's *suat*.

Waller.

Some insensible effluvium, exhaling out of the stone, comes to be checked and condensed by the air on the superficies of it, as it happens to *sweat* on the skins of animals. *Boyle.*

When Lucilius brandishes his pen,
And flashes in the face of guilty men,
A cold *sweat* stands in drops on ev'ry part,
And rage succeeds to tears, revenge to smart.

Dryden.

For him the rich Arabia *sweats* her gum. *Id.*
Beans give in the mow; and therefore those that are to be kept are not to be threshed till March, that they have had a thorough *sweat* in the mow.

Mortimer's Husbandry.

In cold evenings there will be a moisture or *sweat* upon the stool. *Mortimer.*

Those who labour

The *sweaty* forge, who edge the crooked scythe,
Bend stubborn steel, and harden gleening armour,
Acknowledge Vulcan's aid. *Prior.*

Sweat is produced by changing the balance between the fluids and solids, in which health consists, so as that projectile motion of the fluids overcome the resistance of the solids. *Arbuthnot.*

And then, so nice, and so genteel,
Such cleanliness from head to heel,
No humours gross, or frowly steams,
No noisome whiffs, or *sweaty* streams. *Swift.*

SWEAT. See ANATOMY and PERSPIRATION. The excess of sweat dries and weakens the body, deprives the humors of their watery parts, and induces the blood to an inflammatory and atra-

biliary disposition. A sudden suppression of it will hurt as well as a suppression of perspiration. In cases of excessive sweating, from hard labor, many people ruin their health for life, and sometimes even bring on sudden death, by too suddenly exposing themselves to cold air, taking cold drinks, &c. In all cases of excessive perspiration, the most speedy and effectual antidote against all dangerous consequences is a glass of spirits, and keeping moderately warm till the perspiration wear gradually off. All persons exposed by their daily labor to excessive sweating should wear flannel next their skin.

When the temperature of the body is much increased, either by being exposed to a hot atmosphere or by violent exercise, the perspired vapor not only increases in quantity, but even appears in a liquid form. This is known by the name of sweat.

Beside water, it cannot be doubted that carbon is also emitted from the skin; but in what state, the experiments hitherto made do not enable us to decide. Mr. Cruickshanks found that the air of the glass vessel in which his hand and foot had been confined for an hour contained carbonic acid gas; for a candle burned dimly in it, and it rendered lime-water turbid. And Mr. Jurine found that air which had remained for some time in contact with the skin, consisted almost entirely of carbonic acid gas. The same conclusion may be drawn from the experiments of Ingenhousz and Milly. Trousset has lately observed that air was separated copiously from a patient of his while bathing. Beside water and carbon, or carbonic acid gas, the skin emits also a particular odorous substance. That every animal has a peculiar smell is well known: the dog can discover his master, and even trace him to a distance by the scent. A dog, chained up several hours after his master had set out on a journey of some hundred miles, followed his footsteps by the smell. But it is needless to multiply instances of this fact; they are too well known to every one. Now this smell must be owing to some peculiar matter, which is constantly emitted; and this matter must differ somewhat, either in quantity or some other property, as we see that the dog easily distinguishes the individual by means of it. Mr. Cruickshanks has made it probable that this matter is an oily substance; or at least that there is an oily substance emitted by the skin. He wore repeatedly, night and day for a month, the same under waistcoat of fleecy hosiery, during the hottest part of the summer. At the end of this time he always found an oily substance accumulated in considerable masses on the nap of the inner surface of the waistcoat, in the form of black tears. When rubbed on paper it rendered it transparent, and hardened on it like grease. It burned with a white flame, and left behind it a chary residuum.

Berthollet has observed the perspiration acid; and he has concluded that the acid which is present is the phosphoric; but this has not been proved. Fourcroy and Vauquelin have ascertained that the scurf which collects upon the skins of horses consists chiefly of phosphate of lime, and urea is even sometimes mixed with it

According to Thenard, however, who has lately endeavoured more particularly to ascertain this point, the acid contained in sweat is the acetous; which, he likewise observes, is the only free acid contained in urine and in milk, this acid existing in both of them when quite fresh. His account of his examination of it is as follows:—The sweat is more or less copious in different individuals; and its quantity is perceptibly in the inverse ratio of that of the urine. All other circumstances being similar, much more is produced during digestion than during repose. The maximum of its production appears to be twenty-six grains and two-thirds in a minute; the minimum nine grains troy weight. It is much inferior, however, to the pulmonary transpiration; and there is likewise a great difference between their nature and manner of formation. The one is a product of a particular secretion, similar in some sort to that of the urine; the other, composed of a great deal of water and carbonic acid, is the product of a combustion gradually effected by the atmospheric air.

The sweat, in a healthy state, very sensibly reddens litmus paper or infusion. In certain diseases, and particularly in putrid fevers, it is alkaline; yet its taste is always rather saline, and more similar to that of salt than acid. Though colorless it stains linen. Its smell is peculiar and insupportable when it is concentrated, which is the case in particular during distillation. But

before he speaks of the trials to which he subjected it, and of which he had occasion for a great quantity, he describes the method he adopted for procuring it, which was similar to that of Mr. Cruickshanks. Human sweat, according to M. Thenard, is formed of a great deal of water; free acetous acid; muriate of soda; an atom of phosphate of lime, and oxide of iron; and an inappreciable quantity of animal matter, which approaches much nearer to gelatin than to any other substance.

SWEATING. See SWEAT.

SWEATING SICKNESS, a disorder which appeared in England about 1481, and was by foreigners called the English sweat. It returned again in 1485; then in 1506; afterwards in 1517. It appeared again in 1528 or 1529, at which time alone it spread itself to the Netherlands and Germany; a circumstance which shows the impropriety of calling it the English sweat, in Latin sudor Anglicanus: besides Sennertus takes notice that it spread as far as Denmark, Norway, and France. It raged again in 1548. And the last return of it in London was in 1551, when it was so violent as in one day to take off 120 of the inhabitants of Westminster. Some were seized abroad, and cut off in the road, others at home; some when awake, others when fast asleep. Some died in a moment, and others in one, two, three, four, or more hours after they began to sweat.

S W E D E N.

SWEDEN, a considerable kingdom of Northern Europe, extends, including Swedish Lapland, from lat. 55° 20' to 69° N., or about 1000 miles in extreme length; while its breadth varies from between 200 to 300 miles. It contains altogether an area of about 172,000 square miles, of which Swedish Lapland constitutes one-third. Its long. is from about 11° 20' to 23° 20' E. This country lost in 1809 the valuable province of Finland; for which it was professedly compensated, in 1814, by the accession of Norway in exchange for the small province of Swedish Pomerania. The native geographers divide the kingdom into the North, Middle, and Southern Provinces. These are again sub-divided into districts, denominated læns or stadtholderships; but, among the greater part of the inhabitants, the ancient distinction of provinces is still preserved.

The geographical enumeration of the læns is thus given:—

Læns.	Extent in Sq. Miles.	Popula- tion.	Capitals.
<i>Middle Sweden.</i>			
Stockholm city, Drottingholm, Stockholm district . . .	2,624	172,029	Stockholm
Upsal . . .	2,261	84,128	Upsal
Westeras . . .	2,793	84,808	Westeras

Læns.	Extent in Sq. Miles.	Popula- tion.	Capitals.
<i>Middle Sweden.</i>			
Nykoping . . .	2,880	98,761	Nykoping
Orebro . . .	3,670	110,428	Orebro
Carlstadt . . .	6,550	140,100	Carlstadt
<i>South Sweden.</i>			
Gottenburg . . .	1,835	119,514	Gottenburg
Elfsborg . . .	3,008	156,271	Menersborg
Staraborg . . .	3,207	138,410	Mariestad
Linkoping . . .	4,305	162,859	Linkoping
Calmar . . .	4,181	136,296	Calmar
Joenkoping . . .	4,267	117,381	Joenkoping
Cronoberg . . .	3,495	89,631	Merioe
Carlskrona . . .	1,088	63,824	Carlskron
Gotland . . .	1,045	32,988	Wisby
Halmstad . . .	1,963	73,594	Halmstad
Christianstad . . .	2,174	120,547	Christianstad
Malmoe . . .	1,750	149,892	Malmoe
<i>North Sweden.</i>			
Falun or Storakopparberg . . .	12,587	124,816	Falun
Gefleborg . . .	7,765	79,000	Gefleborg
Jaemtland . . .	18,261	32,000	Oestersund
Norrland . . .	10,496	62,000	Hernösund
Maester, and Nordbotteus . . .	64,597	76,000	Una

The chief places, or those containing more than 3000 inhabitants, are as follows:—Stockholm 65,474; Gottenburg 17,760; Carlsrona 10,553; Norrköping 9428; Gefleborg 5930; Malmö 4932; Upsal 4897; Falun 4709; Uddewalla 3971; Wisby 3819; Landskrona 3776; Carlsham 3387; Örebro 3242; Lund 3224; Christianstad 3106; Calmar 3058. Of the towns eighty-eight are denominated cities, and four market towns. They are mostly small, except the few above enumerated. The inhabitants of these

cities and towns, according to the tables of 1815, were 248,029, or one-tenth of the whole population; the other nine-tenths were living in 2214 parishes, containing 65,284 farms.

A curious table, exhibiting a complete view of the population and professions of Sweden, before the separation of Finland, was drawn up by Mr. Nicander, and published in the Transactions of the Swedish Academy of Sciences for 1809, of which the following is an abstract:—

	Number.	
	Males.	Females.
Clergy and teachers of various kinds	13,884	
Exercising civil offices and professions	11,097	
In the war department	57,788	
Various kinds of merchants	6,291	
Seamen, including pilots and light-house keepers	11,313	
Peasants	799,322	
Officers of gentlemen	35,226	
Artists and handicraftsmen	15,705	
Persons free from service and proprietors of lands, &c.	34,309	
Employed in trades and manufactures	30,765	
Artists and tradesmen in towns	26,184	
Children	531,678	
Beggars and prisoners (females 53,993)	24,394	
Laplanders (females 2,968)	2,476	
Married women, widows, and female children		1,279,024
Unmarried women		442,136
Total	1,599,487	1,721,160
Grand total	3,320,647	

The lakes of Sweden are said to occupy an area of 9200 square miles, or one-eighteenth of the whole surface of the country. Wenner, the largest of all, situated in the south-west of the kingdom, communicates with Gottenburg by the canal of Trolhätta, and is likely ere long to communicate with Stockholm by the extension of that canal to the Malar Lake. Other great lakes are the Wetter and the Hjelmars, both to the southward of the capital, and at some distance from it. Of the rivers the Ljusna, the Dal, and the Clara, rise in the mountains bordering on Norway, and flow, the first two into the gulf of Bothnia, the last into the lake of Wenner. From that lake issues the Gotha, which flows southward in a full stream, but not a long course, until reaching the Categat; while the waters of the Wetter Lake are conveyed to the Baltic by the Mottala. The other rivers of Sweden are of secondary size; but on approaching Lapland we meet with streams of some magnitude, flowing into the gulf of Bothnia, viz. the Angerman, the Umea, the Skeftea, the Pitea, the Lulea, the Torneo. In winter, these flowing from frost-bound mountains, are comparatively inconsiderable; but in summer the melting of the snow often swells them prodigiously, and they overflow large tracts of country.

Not more than a twentieth part of Sweden is capable of cultivation, and of that only about one-half is cultivated. The soil, according to Akrel, yields not more than five times the seed that is sown in good years: in ten years the same writer states that one of them fails, two are scanty, five are moderate, and two are abundant.

The deficiency of corn for the support of the inhabitants compels them to mix the rind of the pinus silvestris, and the roots of some bog-plants, with their flour; but the late extensive cultivation of potatoes has been found to afford no valuable aid to the subsistence of the lower classes. Hemp, flax, and tobacco, are grown for domestic use; and hops are cultivated and exported. Altogether the vegetable productions of Sweden are very similar to those of Great Britain, with the exception of several, such as broom, furze, and the walnut-tree, which have not strength to withstand a Swedish winter: but throughout all the temperate part of Sweden the oak, elm, and alder, thrive as in England, while some trees, such as the spruce and Scotch fir, succeed better. Apple, pear, and cherry trees grow but languidly; while berries of many different kinds are produced spontaneously and luxuriantly. Corn and wheat succeed best of course in the southern provinces; oats are raised more generally and in larger quantities; rye and barley are the grain most frequently met with. With respect to the appearance of the oak, Von Buch remarks, 'The course of the boundary of oaks in the northern regions is singular. It distinctly demonstrates the manner in which the climate deteriorates with the distance from the great ocean. In Norway the oaks grow vigorously in the interior of the sea-bays, at Christiansund, and at Molde almost as high as 63°, and even at Drontheim they are not altogether extinct. Harness, on the other hand, does not lie higher than 60° 40'. On the other side of the Bothnian Gulf oaks scarcely go beyond Abo; in the Fin-

nish bays they only cover the coasts to Helsingfors, and on the south side they cannot penetrate beyond Norva in Ingria, so that they do not even reach 60°. Georgi relates that the czar Peter I. ordered oaks to be planted at Petersburg. They grew indeed to the thickness of a man, but irregularly, and with a decayed appearance quite unsuitable to their age and nature. On the road to Moscow they first appear on the banks of the river Masta; and, although the country does not rise in any considerable degree, their boundaries in an eastern direction towards Siberia are to be found in the neighbourhood of Ossa, between Cassan and Catherinenburg, in lat. 57° 30'.

The breeding of cattle is productive, though the races are generally small. In the north the rein-deer is a valuable domestic animal, and some proprietors have herds of more than 1000; goats and pigs are also thinly scattered over the whole country. The fisheries yield employment and numerous articles of export; but the herrings are considerably diminished of late years.

The chief production of the soil is timber; and the far greater part of the dwellings are composed wholly of wood; the demand for wood as fuel is also great; and yet the export of planks, masts, pitch, tar, potashes, and charcoal, forms the chief foreign trade.

The mines of Sweden have long been worked, and long stationary as to product. They average about sixty-four ounces of gold; 12,900 ounces of silver; 24,800 quintals of copper; 431 quintals of lead; 100,000 tons of iron; 22,000 quintals of alum; 35,000 tons of coal; and 65,000 quintals of saltpetre. The manufactures are confined to the few articles required for the home supply, cloths, cottons, silks, and linens, and many smaller articles, being furnished from the different parts of the kingdom, to an annual amount of about £280,000 sterling.

The foreign commerce of Sweden, favored for a time by her neutrality, became after 1807 from her participating in hostilities exposed to great losses; since 1814 it has had its full share also of the fluctuations so general throughout Europe. To these unavoidable evils have been added impediments originating in arbitrary restrictions and prohibitions on the imports. The result is that these imports take place illegally, depriving government of the benefit that would arise from a small duty, disseminating the habit of smuggling, and finally obliging the consumer to pay higher. The export of timber, for instance, was very cramped by the law obliging foreign vessels to pay five per cent. more of duty on it than is paid by the Swedish. The mercantile navy of Sweden consists of about 11,000 vessels, aggregating about 180,000 tons, and navigated by nearly 10,000 seamen. Sweden has suffered greatly from paper currency. In 1657 the bank of Stockholm was conducted with regularity; but since the latter part of the eighteenth century, advances to government have produced an over issue, and consequently a great depreciation of its credit. The exclusive privileges granted to the East India Company, and some smaller associations, are also sources of disadvantage.

The chief exports are iron, copper, timber,

and tar. Herrings may be said to have ceased to form an article of export, the coast being at present deserted. The imports are corn from Poland and Russia, wine from France and the south of Europe; cotton from America and the West Indies; tea from China; sugar, coffee, and other tropical products, from the West Indies.

The *revenue* is derived from the rent of royal domains, a portion of the great tithes, duties on imports and exports, a tax on spirituous liquors, and one of more questionable policy on mines, forges, and chimneys, along with a poll tax and a few monopolies. The amount is about £1,000,000 sterling, and as it never was greater, the military force of Sweden has at no time been so permanent or so large as might have been imagined from its achievements. The troops which crossed the Baltic, along with Gustavus Adolphus, did not exceed 10,000 men; and, though they subsequently received reinforcements, the chief part of his army were Germans. A progressive increase took place towards the close of the eleventh century; but, even in the exploits of Charles XII., a large proportion of his followers were foreigners, supported by foreign resources. In the reign of Gustavus III. the Swedish army was larger; and in 1808, the aid of a British subsidy, £1,200,000 a year, carried it to 50,000 regulars, and a reserve of 30,000. At present it is on a peace establishment, but on a scale abundantly large for the means of the country. There is a national force, or militia, for the levy and support of which, the whole country is divided into petty districts, called *hemmans*, each of which is bound to furnish a soldier, and a spot of land for his maintenance. This land the soldier in time of peace cultivates, being pledged to attend at exercise only a specified number of days in each year: when permanently absent, the inhabitants of the district are bound to cultivate it for him. The officers are supported in the same manner; the colonel by a property placed in the centre of his regiment; the captain by a less extensive lot in the centre of his company, and so on down to the corporal. When in the field, these troops receive the same pay as the rest of the army, but at other times the government supplies only their clothing.

The Swedes were early ranked among the vigorous supporters of the Reformation, having adopted it with great unanimity in the reign of Gustavus Vasa, and having subsequently made the most signal exertions for its maintenance in Germany. The established creed is Lutheranism; and though particular sects, such as the Swedenborgians, have arisen, the dissenters are, on the whole, not numerous. To the Catholics there prevails a general antipathy, nor would it have been prudent, before the latter part of the eighteenth century, for a Catholic priest to have shown himself openly. The ecclesiastical establishment consists of one archbishop, eleven bishops, seventy archdeacons, and 3230 other clergymen.

The university of Upsal, founded in 1477, has in general maintained a high character for physical science. The number of professors is 32

twenty-two: the students necessarily vary; their greatest number (in 1774) was 1500. During the late war they decreased greatly. The university of Lund, in Schonen in the south, is of more recent date, and on a smaller scale: the number of its students at present is about 600. The gymnesia, or high schools, of which the number in the kingdom is eleven, are also well attended of late, having, along with the minor classical establishments, nearly 2000 pupils. Of elementary schools, the number in Sweden is great: the primary or fundamental part of education being, as in Scotland, generally diffused. Government disburses, for the universities and schools of every description, in the shape of salaries, allowances to the poorer students, purchase of books, &c., about £60,000 annually.

The Swedish language bears a great resemblance to the Danish, and not a little to the English, being evidently sprung from the same source as the Saxon or German; but, being little known out of the country, the Swedish men of letters have frequently adopted Latin as the medium of their publications. The necessity of seeking for information in other languages has made the literati in general familiar with German, French, English, and Italian. In natural history, poetry, and general history, the Swedes have several late writers of great merit.

The scientific and literary societies of Stockholm are numerous. An antiquarian society was founded so far back as 1668; a medical society in 1688; and the royal academy of sciences in 1739. In 1753 an academy was founded by the queen for the investigation of subjects connected with the language, the history, and the poetry of Sweden; and, being a numerous association, it was subsequently divided into two sections. The society of sciences at Upsal dates from 1728. Of printing presses in Sweden, the number is only between forty and fifty, of which one-third are in Stockholm; of annual publications, averaging between 300 and 400, one-fourth, or rather more, are translations. On the whole, Sweden is receiving considerable improvements, such as the new modelling of its civil code, and the establishment at Stockholm of a great central school.

In general the Swedes are of fair complexion, resembling the inhabitants of the north of Germany. In the towns this simplicity is less remarkable; but the population of Sweden is, in a great degree, agricultural, which joined to the effect of the reformed faith, and the general diffusion of education, has produced a great degree of honesty among the lower orders. In other respects they have the virtues and defects of a people little advanced in civilisation; highly hospitable on the one hand, they are not, on the other, exempt from the charge of excess in the indulgence of personal appetites. The population being thinly scattered, and the communication far less frequent than in the most retired counties of Wales, ancient usages are kept up, and very slowly modified. Dalecarlia, in particular, remote from the capital, is said to be a province where hereditary customs are handed down from age to age.

The government of Sweden is a limited mon-

archy, now hereditary in the male line of Bernadotte: in case of the failure of males in that family, a successor is to be nominated by the king, and approved by the legislature. The appointed civil list is 320,000 rix dollars banco, or about £50,000 sterling for the king; that of the crown prince one-third. The states are composed of 1100 nobles, fifty to eighty clergy, from 100 to 200 burgesses, and 100 peasants, who vote by classes, not by the head. They must assemble every fifth year, and more frequently if convened by the king. They make laws, grant taxes, regulate the coinage and the press, and superintend the administration of justice. The laws are contained in a volume of 480 pages, which is looked up to with much veneration from its antiquity, having been adopted as early as the year 1442. All new cases of differences that occur are referred to the principles of this fundamental code. There are courts of revision and of appeal, however, and lawyers find or make a trade here.

The public expenses may be said to be rigidly watched, and have recently been considerably reduced; at present they stand thus:—

Establishment of the royal households	£210,000
For the senators and the government	180,000
For the judicial and police branches	50,000
For the military branch	370,000
For the marine branch	180,000
For extraordinary expenses, including interest on the public debt	150,000
	<hr/>
	£1,140,000

The public income is nearly commensurate with the expenditure. The public debt, 16th of April 1819, amounted to 6,371,862 Reichsthalern banco, or about £1,387,500 sterling; having been reduced £250,000 since the year 1813. It is wholly owing to residents in Sweden; and, on the plan of a sinking fund now in progress, will be extinguished in fourteen years. The chief financial evil under which the kingdom suffers is from the vast quantity of paper money which still circulates, but measures are in train by which this paper is gradually to be withdrawn.

The early history of Sweden is no less involved in fables than that of most other nations. Alstedius gives a chronological list of 149 monarchs of Sweden, from Magog, the son of Japhet, and grandson of Noah, who, he says, began to reign in Sweden and Gothland, A. M. 1745, eighty-eight years after the flood, to queen Christina, in 1633. Others affirm that ancient Scandinavia was first governed by judges elected for a certain time by the voice of the people. Among these temporary princes the country was divided, until A. M. 2054, when Eric I. was raised to the supreme power, with the prerogatives of all the temporary magistrates united in his person for life. From this very early period, till 1366 of the Christian era, the histories of Sweden, present us with nothing but what is common to all nations in their early periods, viz. the endless combats and massacres of barbarians, tending to no other purpose than the effusion of blood, and the temporary acquisition of a little ter-

ritory. At this time, however, Albert of Mecklenburg, having concluded a peace between Sweden and Denmark, which had been at violent war for some time before, was proclaimed king of Sweden.

Sweden until the appearance of Gustavus Vasa.—The peace above mentioned was of short duration, being broken in 1368; on which Albert entered into an offensive and defensive league with the earl of Holstein, the Jutland nobility, the dukes of Sleswick, Mecklenburg, and the Hanse Towns, against the kings of Denmark and Norway. Albert proved very successful against Waldemar king of Denmark at that time, driving him entirely out of his dominions; but he himself was defeated by the king of Norway, who laid siege to his capital. Soon after this a new treaty of peace was concluded, by which Albert was allowed to enjoy the crown of Sweden in peace. However, having formed a design of rendering himself absolute, he fell under the displeasure of his subjects, and Margaret of Norway was proclaimed queen of Sweden by the malcontents. A war immediately ensued, in which Albert was defeated and taken prisoner; but as the princes of Mecklenburg, the earls of Holstein, and the Hanse Towns, entered into a league in his favor, the war was so far from being extinguished by this event, that it raged with more fury than ever. At length, in 1394, the contending parties came to an accommodation. Albert was set at liberty, on condition that he should in three years surrender to Margaret all pretensions to the city of Stockholm; and the Hanse Towns engaged to pay 60,000 marks of silver in case of Albert's breach of faith. Not long after this, Eric the son of Albert died; and he, having no other child, did not think it worth his while to contend for the kingdom of Sweden: he therefore acquiesced in the pretensions of Margaret, and passed the remainder of his days at Mecklenburg. Margaret died in 1412 or 1415. See DENMARK.

Margaret was succeeded by Eric XIII. of Pomerania. This prince's reign was cruel and oppressive to the last degree. The people were ruined by taxes; and the Danes, being every where preferred to the offices of power, committed the greatest cruelties. The consequence of this was a revolt; and Charles Canutson, grand mareschal of Sweden and governor of Finland, having joined the malcontents, was declared commander in chief of their army. Eric was now formally deposed, and commenced pirate: Canutson was chosen regent: but beginning to oppress the people, and aspiring openly at the crown, the Swedes and Danes revolted; in consequence of which a revolution took place, and Christopher duke of Bavaria, nephew to Eric, was chosen king of Denmark, Sweden, and Norway, in 1442. On the accession of the new prince, complaints against Canutson were brought from all quarters; but, through the interest of his friends, he escaped punishment; and in 1448, Christopher having died after a tyrannical reign of five years, he was raised to the throne by the name of Charles VIII. However, the kingdoms of Denmark and Norway refused to own allegiance to him; upon which a war imme-

diately commenced. In 1454 peace was concluded, and Denmark for the present freed from the Swedish yoke. Neither did Charles VIII. long enjoy the crown of Sweden: Having quarrelled with the archbishop of Upsal, the latter formed such a strong party that the king could not resist him. Christian I. king of Denmark was called to the throne of Sweden; and, in 1459, once more united the three kingdoms. But, having begun to oppress his subjects in an arbitrary manner, he was soon after obliged to retire to Denmark in 1463. Katil bishop of Linköping, who had driven out the king, took upon himself the office of regent. Next year Christian returned with a powerful army, but was defeated. The people then recalled Charles; but he, on his accession, having offended bishop Katil, was by him defeated, and obliged to renounce his right to the crown. After this the kingdom was rent into factions, between whom the most cruel civil wars took place, until 1467, when Charles was again recalled, and enjoyed the kingdom, though not without opposition, till his death, in 1470.

The confusion in which the Swedish affairs had been so long involved did not cease on the death of Charles. Christian again invaded Sweden; but was defeated by Steno Sture, nephew of the late king. After this the kingdom remained in peace till 1487, when the Russians invaded Carelia, committing every where the greatest ravages. These were soon driven out: but in 1497, a rupture happening between Sture and the senate, an offer was made of the Swedish crown to John king of Denmark, who readily accepted the offer, and was crowned accordingly: but no sooner was he seated on the throne than he became odious to the Swedes, from his partiality to the Danes. In a short time he set out for Denmark, leaving his queen with a strong garrison in the citadel of Stockholm. He was no sooner gone than the capital was invested; and, though the queen made a noble defence, she was obliged to capitulate, on condition of being allowed to pass into Denmark. All the garrison were made prisoners of war, and the queen was confined in a monastery till 1498. The Swedish affairs continued to be involved in the same dreadful confusion until 1520, when a great revolution was effected by Gustavus Vasa, the son of Eric Vasa, a nobleman of the first rank, who restored the kingdom to its liberty, and laid the foundation of its future grandeur. The occasion of this great revolution was as follows:—In 1518 Christian II. king of Denmark invaded Sweden, with a design to subdue the whole country; but being defeated with great loss by young Steno Sture, then regent, he set sail for Denmark. But, meeting with contrary winds, he made several descents on the Swedish coast, which he ravaged with all the fury of an incensed barbarian. The inhabitants, however, bravely defended themselves, and Christian was reduced to the utmost distress: one-half of his forces having perished with hunger, and the other being in the most imminent danger by the approach of a rigorous winter. He then thought of a stratagem, which almost proved fatal to the regent; for having invited him to a conference, at which he designed

either to assassinate or take him prisoner, Sture was about to comply, had not the senate, who suspected the plot, interposed and prevented him. Christian then offered to go in person to Stockholm to confer with Sture, upon condition that six hostages should be sent in his room. This was accordingly done; but, the wind happening then to prove favorable, he set sail for Denmark with the hostages. Next year he returned; and, having drawn Sture into an ambush, the regent received a wound of which he died soon after. The kingdom being thus left without a head, matters soon came to the most desperate crisis. The army disbanded itself; and the senate, instead of taking proper measures to oppose the enemy, spent their time in idle debates. Christian, in the mean time, advanced into the heart of the kingdom, destroying every thing with fire and sword; but, on his arrival at Stragnez, he granted a suspension of arms, to give the people time to deliberate on their situation, and to reflect that they might easily get rid of their troubles by electing him king. This they accordingly did; and Christian proved one of the most bloody tyrants that ever sat on the throne of any kingdom. Immediately after his coronation, he gave grand entertainments for three days; during which time he projected the diabolical design of extirpating at once all the Swedish nobility, and actually executed above sixty people of the first rank. Innumerable other cruelties were committed. At last he departed for Denmark, ordering gibbets to be erected, and causing the peasants to be hanged on them for the slightest offences, as he passed along; and at Jencoping he caused two boys to be whipped to death.

Sweden under, and to the death of, Gustavus I.
—This monstrous cruelty, instead of securing him on the throne, exasperated the whole nation against him. Gustavus Vasa was among the hostages whom Christian had perfidiously carried to Denmark in 1519. Large promises had been made to reconcile him to Christian, and threats had been used for the same purpose, but all in vain. Banner, a Danish nobleman, prevailed on the king to put him into his hands, to try whether he could prevail upon him to change his sentiments. The king, however, told Banner, that he must pay 6000 crowns in case the prisoner should make his escape. Banner generously assented; and, having brought the noble prisoner to his fortress of Calo in Jutland, soon allowed him all the liberty he could desire, and otherwise heaped favors upon him. All this, however, could not extinguish his remembrance of the cruelties of Christian, and the desire he had of being serviceable to his country. He therefore determined to make his escape. With much difficulty, and under various disguises, he effected his escape, which Banner was no sooner acquainted with than he set out after him, and found him at Lubec. He reproached him as ungrateful and treacherous; but he was soon appeased by the arguments urged by Gustavus, and by the promise he made of indemnifying him for the loss of his ransom. Upon this Banner returned, giving out that he could not find his prisoner. Christian, enraged at his escape, ordered Otho his

general to do his utmost to arrest him. Gustavus applied to the regency for a ship to convey him to Sweden, but the captain steered a different course, and put him on shore near Calmar; a city hitherto garrisoned by the troops of Christina, widow of the regent. When Gustavus arrived, he made himself known to the governor and the principal officers of the garrison, who were mostly Germans, and his fellow soldiers in the late administrator's army. He flattered himself that his birth, his merit, and his connexions, would immediately procure him the command. But they, seeing him without troops and without attendants, threatened to kill or betray him if he did not instantly quit the city. Thus disappointed, Gustavus departed with great expedition; and, his arrival being known, he was again forced to have recourse to disguise to conceal himself from the Danish emissaries who were in search of him. In a waggon, loaded with hay, he passed through every quarter of the Danish army, and at last repaired to an old family castle in Sudermania. Hence he wrote to his friends, notifying his return to Sweden, and beseeching them to assemble all their forces to break through the enemy's army into Stockholm, at that time besieged; but they, too, refused to embark in so hazardous and desperate an attempt. He next applied to the peasants; but they also refused to engage. At length, after several vain attempts to throw himself into Stockholm, and disappointed in all his hopes, he determined to apply to the Dalecarlians. Attended by a peasant, to whom he was known, he travelled in disguise through Sudermania, Nericia, and Westermania, and, after a laborious and painful journey, arrived in the mountains of Dalecarlia. Scarcely had he finished his journey, when he found himself deserted by his companion and guide, who carried off with him all the money he had provided for his subsistence. Thus forlorn, destitute, half starved, he entered among the miners, and wrought like a slave under ground; here he continued until he was discovered accidentally by a gentleman, his acquaintance, in the neighbourhood, who offered him an asylum in his house. This he joyfully accepted; but, finding it impossible to make him take arms in his behalf, he fled to the house of one Peterson with whom he had formerly served. This last proved a traitor to his friend, and Gustavus would have been delivered to the Danes had he not received timely warning from the wife of his host. By her advice he took refuge with a clergyman, who shut him up in an apartment adjoining to the church, and counselled him to apply at once to the peasants at an approaching annual festival. They listened to him with enthusiasm, and he instantly led them against the governor's castle; which he took by assault, and put the garrison to the sword. This inconsiderable enterprise was attended with the most happy consequences. Great numbers of the peasants flocked to his standard; some of the gentry openly espoused his cause, and others supplied him with money. Christian was soon acquainted with what had passed; but, despising such an inconsiderable enemy, he sent only a slender detachment, under the command of one Soren Norby, to assist his

adherents in Dalecarlia. Gustavus advanced with about 5000 men, and defeated a body of Danes commanded by one Meleen; but he was strenuously opposed by the archbishop of Upsal, who raised numerous forces for king Christian. The fortune of Gustavus, however, still prevailed, and the archbishop was defeated with great loss.

Gustavus then laid siege to Stockholm; but, his force being too inconsiderable for such an undertaking, he was forced to abandon it with loss. This check did not prove in any considerable degree detrimental to the affairs of Gustavus; the peasants from all parts of the kingdom flocked to his camp, and he was joined by a reinforcement from Lubec. Christian, unable to suppress the revolt, wreaked his vengeance on the mother and sisters of Gustavus, whom he put to death with the most excruciating torments. Several other Swedish ladies he caused to be thrown into the sea, after having imposed on them the inhuman task of making the sacks in which they were to be enclosed. His barbarities served only to make his enemies more resolute. Gustavus, having assembled the states at Wadstena, was unanimously chosen regent, the diet taking an oath of fidelity to him, and promising to assist him to the utmost. Having thus obtained the sanction of legal authority, he pursued his advantages against the Danes. A body of troops appointed to throw succors into Stockholm were totally cut in pieces; and the regent, sending some troops into Finland, struck the Danes there with such terror that the archbishop of Upsal, together with Slaborg and Baldenacker the Danish governors, fled to Denmark. He then sent express orders to all his governors and officers in Finland and Sweden to massacre the Swedish gentry without distinction. The Swedes made reprisals by massacring all the Danes they could find; so that the whole country was filled with bloodshed and slaughter. In the mean time Gustavus had laid siege to the towns of Calmar, Abo, and Stockholm; but Norby obliged him to raise all of them with loss. Gustavus, in revenge, laid siege to the capital a third time, and petitioned the regency of Lubec for a squadron of ships, and other succors, for carrying on the siege. This was complied with, but on very hard conditions, viz. that Gustavus should oblige himself, in the name of the states, to pay 60,000 merks of silver as the expense of the armament; that, until the kingdom should be in a condition to pay that sum, the Lubec merchants trading to Sweden should be exempted from all duties on imports or exports; that all other nations should be prohibited from trading with Sweden, and that such traffic should be deemed illicit; that Gustavus should neither conclude a peace, nor even agree to a truce with Denmark, without the concurrence of the regency of Lubec; and that, in case the republic should be attacked by Christian, he should enter Denmark at the head of 20,000 men. Upon these hard terms did Gustavus obtain assistance from the regency of Lubec; nor did his dear bought allies prove very faithful. They did not indeed go over to the enemy; but in a sea-fight, where the Danes were entirely in the power of their

enemies, they suffered them to escape, when their whole force might have been entirely destroyed. This treachery had well nigh ruined the affairs of Gustavus; for Norby was now making preparations effectually to relieve Stockholm; in which he probably would have succeeded: but, at this critical period, news arrived that the Danes had unanimously revolted, and driven Christian from the throne; and that the king had retired into Germany, in hopes of being restored by the arms of his brother-in-law, the emperor. On hearing this news, Norby retired with his whole fleet to the island of Gothland, leaving but a slender garrison in Calmar. Gustavus did not fail to improve this opportunity to his own advantage, and quickly made himself master of Calmar. Meantime Stockholm continued closely invested; but Gustavus protracted the siege until he should get himself elected king. Having for this purpose called a general diet, the first step was to fill up the vacancy in the senate occasioned by the massacres of Christian. Gustavus had the address to get such nominated as were in his interest; and of consequence the assembly was no sooner met than a speech was made containing the highest encomiums on Gustavus, setting forth in the strongest light the many eminent services he had done for his country, and concluding that the states would show themselves equally ungrateful and blind to their own interest if they did not immediately elect him king. This proposal was acceded to by such tumultuous acclamations that it was impossible to collect the votes; so that Gustavus himself acknowledged that their affection exceeded his merit, and was more agreeable to him than the effects of their gratitude.

Gustavus on his election was urged to have the ceremony of his coronation immediately performed; but the king, having some designs on the clergy, did not think proper to comply with their request, as he would have been obliged to take an oath to preserve them in their rights and privileges. Indeed he had not been long seated on the throne before he incurred the displeasure of that body; for, having large arrears due to the army, with other incumbrances, Gustavus found it necessary to raise large contributions on the clergy. On this he was accused of avarice and heresy before the pope's nuncio. Gustavus defended himself against these accusations; and soon after showed a great partiality for the doctrines of Luther, which by this time had been preached and received by many people in Sweden. This embroiled him more than ever with the clergy; and it soon appeared that either Gustavus must resign his throne, or the clergy some part of the power they had assumed. Matters were driven to extremities by the king's allowing the Scriptures to be translated into the Swedish language. In 1526 the king, finding them entering into a combination against the reformists, went to Upsal, and publicly declared his resolution of reducing the number of oppressive and idle monks and priests, who, under the pretence of religion, fattened on the spoils of the industrious people. At last, taking advantage of the war between the pope and Charles V. of Spain, he declared himself to be of the reformed religion.

and established it throughout his dominions; and at the same time, to humble the arrogance of the ecclesiastics, he gave the senators the precedence of them, and in many other respects degraded them from the dignities they formerly enjoyed. For some time the states hesitated at supporting the king in his work of reformation; insomuch that at last he threatened to resign the kingdom, which he said was doomed to perpetual slavery either to its temporal or spiritual tyrants. On this the states came into his measures, and retrenched the privileges of the ecclesiastics in the manner he proposed. Several disturbances however ensued. An impostor, who pretended to be of the family of Sture, the former regent, having claimed the throne, the Dalecarlians revolted in his favor; but, on the approach of a powerful army sent by Gustavus, they submitted. Soon after Lutheran professors were established in every diocese; upon which a new rebellion ensued. At the head of this was Thure Johanson, who had married the king's sister. Several of the nobility joined him; and the king of Denmark acceded to their cause, thinking, by means of these disturbances, to reunite the three kingdoms of Sweden, Denmark, and Norway, as formerly. But Gustavus prevailed, and the rebels were obliged to take refuge in Denmark. A fresh accident, however, had like to have embroiled matters worse than before. The subsidy granted to the regency of Lubec was still due; and for the payment of it the states granted to the king all the useless bells of the churches and monasteries. The people were shocked at the sacrilege; and the Dalecarlians again betook themselves to arms. Intimidated, however, by the courage and vigorous conduct of the king, they again submitted, and were taken into favor. But tranquillity was not yet restored. Christian, having established a powerful interest in Norway, once more made an attempt to recover his kingdoms, and was joined by the Dalecarlians; but, being defeated by the Swedish forces, he was forced to return to Norway, where, being obliged to capitulate with the Danish generals, he was kept prisoner all his life. In 1542 Gustavus, having happily extricated himself out of all his troubles, prevailed on the states to make the crown hereditary in his family; after which he applied himself to the encouragement of learning and commerce. A treaty was set on foot for a marriage between his eldest son Eric and Elizabeth queen of England. The prince's brother, duke John, went over to England, and resided for some time at the court of London with great splendor. He returned full of expectations of success; but, bringing with him no sort of proofs in writing, his father soon perceived that he had been the dupe of Elizabeth's superior policy. However, at last he allowed prince Eric to go in person to England; but, before he could embark, the death of Gustavus, in 1569, made him lay aside all thoughts of the voyage and marriage.

Sweden, until the death of Gustavus Adolphus.

—Gustavus Vasa was succeeded by his son Eric XIV. The new king was a man possessed of all the exterior ornaments which give an air of dignity to the person; but he had neither the

prudence nor the penetration of his father. He created the first nobility that were ever known in Sweden; which he had no sooner done than he quarrelled with them, by passing some acts which they thought derogatory to their honor and dignity. The whole course of his reign was disturbed by wars with Denmark, and disputes with his own subjects. In the former he was unfortunate, and towards the latter he behaved with the greatest cruelty. At last, by the torments of his own conscience, it is said, he ran mad. He afterwards recovered his senses, but was dethroned by his brothers; of whom duke John, who had been hitherto kept prisoner by Eric, succeeded him in the kingdom.

This revolution took place in 1568, but with no great advantage to Sweden. Disputes about religion between the king and his brother, and wars with Muscovy, threw matters into the utmost confusion. At last prince Sigismund, the king's son, was chosen king of Poland, which proved the source of much trouble to the kingdom. See POLAND. In 1590 king John died; and, as Sigismund was at a distance, every thing fell into the utmost confusion; the treasury was plundered, and the wardrobe quite spoiled, before even duke Charles could come to Stockholm to take the administration into his hands, until king Sigismund should return. This, however, was far from being the greatest disaster which befel the nation at this time. It was known that the king had embraced the popish religion, and it was with good reason suspected that he would attempt to restore it upon his arrival in Sweden. Sigismund also was obliged, on leaving Poland, to promise that he would stay no longer in Sweden than was necessary to regulate his affairs. These circumstances served to alienate the minds of the Swedes from their sovereign, even before they saw him; and the universal dissatisfaction was increased, by seeing him attended, on his arrival in Sweden in 1593, by Malaspina the pope's nuncio, to whom he made a present of 30,000 ducats to defray the expenses of his journey to Sweden. What the people had foreseen was too well verified; the king refused to confirm the Protestants in their religious privileges, and showed such partiality on all occasions to the Papists that a party was formed against him; at the head of which was duke Charles his uncle. Remonstrances, accompanied with threats, took place on both sides; and, at an interview between the king and Charles, the dispute would have ended in blows, had they not been parted by some of the nobility. This, however, made such an impression upon Sigismund that he was apparently reconciled to his brother, and promised to comply with the inclinations of the people in every respect, though without any inclination to perform what he promised. The agreement indeed was scarcely made, before Sigismund conceived the horrid design of murdering his uncle at the Italian comedy, acted the night after his coronation. The duke, however, having notice of the plot, avoided it. This enraged the king so much that he resolved to accomplish his design by force; and therefore commanded a Polish army to march towards the frontiers of Sweden, where

they committed all the ravages that could be expected from an enraged and cruel enemy. Complaints were made by the Protestant clergy to the senate; but no other reply was made them than that they should abstain from these bitter invectives and reproaches, which had provoked the Catholics, until the king's departure; at which time they would be more at liberty. In 1595 Sigismund set sail for Dantzic, leaving the administration in the hands of duke Charles. The consequence of this was that, the dissensions which had already taken place being continually increased by the obstinacy of the king, duke Charles assumed the sovereign power; and in 1604 Sigismund was formally deposed, and his uncle Charles IX. raised to the throne. He proved a wise and brave prince, restoring the tranquillity of the kingdom, and carrying on a war with vigor against Poland and Denmark. He died in 1611, leaving the kingdom to his son, the celebrated Gustavus Adolphus.

Though Charles IX. by his wise and vigorous conduct had in a great measure retrieved the affairs of Sweden, they were still in a very disagreeable situation. The finances of the kingdom were entirely drained by a series of wars and revolutions; powerful armies were preparing in Denmark, Poland, and Russia; while the Swedish troops were not only inferior in number to their enemies, but the government was destitute of resources for their payment. Though the Swedish law required that the prince should have attained his eighteenth year before he was of age, yet such striking marks of the great qualities of Gustavus appeared, that he was allowed by the states to take upon him the administration even before this early period. His first act was to resume all the crown grants, that he might be the better able to carry on the wars in which he was unavoidably engaged; and to fill all places, both civil and military, with persons of merit. At the head of domestic and foreign affairs was placed chancellor Oxenstiern, a person every way equal to the important trust, and the choosing of whom impressed mankind with the highest opinion of the young monarch's penetration and capacity. Soon after his accession, Gustavus received an embassy from James I. of Britain, exhorting him to make peace with his neighbours. This was seconded by another from Holland. But, as the king perceived that the Danish monarch intended to take every opportunity of crushing him, he resolved to act with such vigor as might convince him that he was not easily to be overcome. Accordingly he broke into Denmark with three different armies at once; and though the enemy's superiority at sea gave them great advantages, and the number of the king's enemies distracted his attention, he carried on the war with such spirit that in 1613 a peace was concluded upon good terms. This war being finished, the king applied himself to civil polity, and made some reformations in the laws of Sweden. In 1615 hostilities were commenced against Russia, on account of the refusal of that court to restore some money which had been formerly lent them. The king entered Ingria, took Kexholm by storm, and was laying siege to Plescow, when, by the mediation of

James I., peace was concluded, on condition of the Russians repaying the money, and yielding to Sweden some part of their territory. In this and the former war, notwithstanding the shortness of their duration, Gustavus learned the rudiments of the military art for which he soon became so famous. In one campaign he not only learned, but improved, all the military maxims of La Gardie, a celebrated general, brought the Swedish army in general to a more steady and regular discipline than formerly had been exercised, and formed and seasoned an invincible body of Finlanders, who had afterwards a very considerable share in the victories of the Swedes. Peace was no sooner concluded with Russia than Gustavus was crowned with great solemnity at Upsal. Soon after this, Gustavus ordered his general La Gardie to acquaint the Polish commander, Czekowicz, that as the truce between the two kingdoms, which had been concluded for two years, was now expired, he desired to be certainly informed whether he was to expect peace or war from his master. In the mean time, having borrowed money of the Dutch for the redemption of a town from Denmark, he had an interview on the frontiers with Christian IV. At this interview the two monarchs conceived the utmost esteem and friendship for each other; and Gustavus obtained a promise that Christian would not assist Sigismund in any designs he might have against Sweden. In the mean time, receiving no satisfactory answer from Poland, Gustavus began to prepare for war. Sigismund entered into a negotiation, and made some pretended concessions, with a view to seize Gustavus by treachery; but, the latter having intimation of his design, the whole negotiation was changed into reproaches and threats on the part of Gustavus. Immediately after this Gustavus made a tour in disguise through Germany, and married Eleonora, the daughter of the elector of Brandenburg. He then resolved to enter heartily into a war with Poland, and with this view set sail for Riga, with a great fleet, which carried 20,000 men. The place was well fortified, and defended by a body of veterans enthusiastically attached to Sigismund; but it was carried after a siege of six weeks, accompanied by much desperate fighting.

After the reduction of Riga, the Swedish monarch entered Courland, where he reduced Mittau; but ceded it again on the conclusion of a truce for one year. Sigismund, however, no sooner had time to recover himself than he began to form new enterprises against the Swedes in Prussia; but Gustavus setting sail with his whole fleet for Dantzic, where the king of Poland then resided, so broke his measures that he was obliged to prolong the truce for another year. Sigismund, however, was not yet apprised of the danger he was in, and refused to listen to any terms of accommodation; upon which Gustavus, entering Livonia, defeated the Polish general, and took Dorpt, Hockenhausen, and several other places of less importance; after which, entering Lithuania, he took the city of Birsen. Notwithstanding this success, Gustavus proposed peace on the same equitable terms

as before; but Sigismund was still infatuated with the hopes that, by means of the emperor of Germany, he should be able to conquer Sweden. Gustavus, finding him inflexible, resolved to push his good fortune. His generals, Horn and Thurn, defeated the Poles in Semigallia. Gustavus himself with 150 ships set sail for Prussia, where he landed at Pulaw. This place was immediately delivered up to him; as were also Brannsborg, Frauenberg, Elbing, Marienburg, Mew, Dirschau, Stum, Christburg, &c. Sigismund, alarmed at the great successes of Gustavus, sent a body of forces to oppose him, and to prevent Dantzic from falling into his hands. In this he was attended with as bad success as before. His troops were defeated before Marienburg, Mew, and Dirschau; and in May, 1627, Gustavus arrived with fresh forces before Dantzic, which he would probably have carried had he not been wounded in the belly by a cannon shot. The Poles in the mean time recovered Mew; and the States of Holland sent ambassadors to mediate a peace between the two crowns. Sigismund, however, depending upon the assistance of the emperor of Germany and king of Spain, determined to hearken to no terms, and resolved to make a winter campaign; but Gustavus was so well intrenched, and all his forts were so strongly garrisoned, that the utmost efforts of the Poles were to no purpose. Dantzic in the mean time made such a desperate resistance as greatly irritated Gustavus. In a sea engagement the Swedish fleet defeated that of the enemy; after which Gustavus, having blocked up the harbour with his fleet, pushed his advances on the land side with incredible vigor. He made a surprising march over a morass fifteen miles broad, assisted by bridges of a peculiar construction, over which he carried a species of light cannon invented by himself. By this unexpected manœuvre he got the command of the city in such a manner that the garrison were on the point of surrendering, when, by a sudden swell of the Vistula, the Swedish works were ruined, and the king was obliged to raise the siege. In other respects, however, the affairs of Gustavus went on with their usual good fortune. His general, Wrangel, defeated the Poles before Brodnitz; and at Stum the king gained another and more considerable victory in person. In addition to these misfortunes of the Poles, a famine and plague raged in their camp, so that they were at last obliged to consent to a truce for six years, to June 1635. Gustavus restored some places, but kept the port and citadel of Memel, the harbour of Pillau, the town of Elbing, Bransbergh, and all that he had conquered in Livonia.

Gustavus having thus brought the war with Poland to an honorable conclusion, began to think of resenting the conduct of the emperor in assisting his enemies and oppressing the Protestant states. Before embarking in such an important undertaking it was necessary that he should consult the diet. In this the propriety of engaging in a war with Germany was warmly debated; but, after much altercation, Gustavus, in a very noble speech, determined the matter; and set forth in such strong terms the virtuous motives

by which he was actuated that the whole assembly wept, and every thing was granted which he could require. It was not difficult for Gustavus to begin his expedition. His troops amounted to 60,000 men, hardened by a succession of severe campaigns in Russia, Finland, Livonia, and Prussia. His fleet exceeded seventy sail, carrying from twenty to forty guns, and manned with 6000 mariners. Embarking his troops, he landed at Usedom on the 24th of June 1730, the Imperialists having evacuated all the fortresses they possessed there; and the isle of Rugen had been before reduced by general Lesly, in order to secure a retreat if fortune should prove unfavorable. Passing the frith Gustavus stormed Wolgast and another strong fortress in the neighbourhood, leaving general Banner with a garrison for the defence of these conquests. He then proceeded to Stettin; which was no sooner invested than it consented to receive a Swedish garrison, and the king persuaded the duke of Pomerania to enter into an alliance with him. In consequence of this the Swedish troops were received into several towns of Pomerania; and the most bitter enmity took place between the Imperialists and Pomeranians, each refusing the other quarter. These successes of Gustavus struck the empire with consternation; for, being already overwhelmed with civil dissensions, they were in no condition to resist so impetuous an enemy. At this time also the Imperialists were without a general; but at last count Tilly was fixed upon, and invested with the dignity of Field Marshal. In the mean time the king, being reinforced by a considerable body of troops in Finland and Livonia under Gustavus Horn, defeated the Imperialists before Griffenhagen, taking the place soon after by assault. By this and some other conquests he opened a passage into Lusatia and Silesia; but, in the mean time, count Tilly cut off 2000 Swedes at New Brandenburg, owing to the obstinacy of their commander Kniphausen, who had orders to evacuate the place and join the main army. This advantage, however, was soon overbalanced by the conquest of Frankfort on the Oder, which Gustavus took by assault, making the whole garrison prisoners. Thus he commanded the rivers Elbe and Oder on both sides, and had a fair passage not only to these countries, but also to Saxony and the dominions of the house of Austria. Soon after this Gustavus laid siege to Landsberg, which he took by assault; though the number of soldiers he had with him was so inconsiderable that he had thoughts of sending to the main army for a reinforcement: before the prisoners should march out, being apprehensive that they might give him battle in the open field, though they could not defend themselves behind walls. About this time the Protestant princes held a diet at Leipsic; to which Gustavus sent deputies, and conducted his negotiations with such address as tended greatly to promote his interests. Immediately after this he reduced Gripswald, and with it all Pomerania. Then, marching to Custrow, he restored the dukes of Mecklenburg to their dominions. Here the Imperialists had tyrannised in such a manner that Gustavus was received as the deliverer of the people; and the ceremony of the duke's inau-

guration was performed with great solemnity. All this time count Tilly was employed in the siege of Magdeburg; but now, being alarmed at the repeated successes of the Swedes, he left Pappenheim with part of the army before that city, while he marched with the rest into Thuringia, to attack the landgrave of Hesse-Cassel and the elector of Saxony. After a most obstinate defence Magdeburg fell into the hands of Pappenheim, where he committed all imaginable cruelties. Gustavus formed a plan of recovering the city; but, relinquishing it, he ordered Banner to attack Havelburg; which was done with such resolution that the place was forced in a few hours, and all the garrison made prisoners. Werben was next obliged to submit after an obstinate conflict, in which many fell on both sides. These successes obliged count Tilly to attempt in person to check the progress of the Swedes. He detached the vanguard of his army, composed of the flower of the imperial cavalry, within a few miles of the Swedish camp. An action ensued, in which Bernstein the imperial general was defeated and killed, with 1500 of his men. Gustavus, after this advantage, placed himself in a situation so much superior to his enemies that count Tilly was fired with indignation, and marched up to the Swedish lines to give him battle. Gustavus kept within his works, and Tilly attacked his camp, though almost impregnable fortified, keeping up a most terrible fire from a battery of thirty-two pieces of cannon; which, however, produced no other effect than obliging the Swedish monarch to draw up his army behind the walls of Werben. Tilly had placed his chief hopes in being able to nail up the enemy's cannon, or set fire to their camp in divers quarters; after which he proposed making his grand attack. With this view he bribed some prisoners; but they betrayed him and told his design to Gustavus. The king ordered fires to be lighted in different parts of his camp, and his soldiers to imitate the noise of a tumultuous disorderly rabble. This had the desired effect. The count led his army to the breach made by the cannon; where he was received with such a volley of grape-shot as cut off the first line, and put the whole body in disorder, so that they could never be brought back to the charge. In this confusion the imperial army was attacked by Bauditz, and, after an obstinate conflict, obliged to quit the field.

Soon after this action the queen arrived at the camp with a reinforcement of 8000 men; at the same time a treaty was concluded with Charles I. of England, by which that monarch allowed the marquis of Hamilton to raise 6000 men for the service of Gustavus. These auxiliaries were to be conducted to the main army by a body of 4000 Swedes; and were in every thing to obey the king while he was personally present, but in his absence were to be subject to the orders of the marquis. With these troops the king had resolved to make a diversion in Bremen; but the marquis, finding it impossible for him to effect a junction with the Swedish army, resolved, without debarking his troops, to steer his course for the Oder, and land at Usedom. Gustavus was very much displeas'd at finding his project thus

disconcerted; however, making the best of the existing circumstances, he commanded the British troops to act on the Oder instead of the Weser. The number of this little army was magnified exceedingly by report, insomuch that count Tilly had some thoughts of marching against them with his whole force; but, on the departure of the marquis for Silesia, he reinforced the army in that country with a large detachment, which was thought to contribute not a little to the defeat he soon after received. Ever since the late action, Gustavus had kept within his entrenchments, where his army was well provided with every thing. Tilly made several attempts to surprise or draw him to an engagement; but, finding all his endeavours fruitless, he marched into Saxony and laid siege to Leipzig. This precipitate measure proved highly advantageous to the Swedish monarch; as thus the elector, who had been wavering in his resolutions, was now obliged to have recourse to the Swedes, to preserve himself from utter destruction. A treaty offensive and defensive was immediately concluded with Gustavus: and the elector willingly promised every thing that was required of him; and, among the rest, that not only the prince his son, but he himself should reside in the Swedish camp and engage his life and fortune in the common cause. Tilly, in the mean time, carried fire and sword into the unhappy electorate. At the head of an army of 44,000 veterans, he summoned Leipzig to surrender; denouncing the same vengeance against it as had been executed on Magdeburg, in case of a refusal. By this the governor was so much intimidated that he instantly submitted; and also surrendered the castle of Passenberg, which was in a condition to have stood out till the arrival of the Swedish army. The elector, enraged at the loss of these valuable places, ordered his army to join the Swedes with all expedition, and pressed the king so warmly to engage that at last he yielded to his desire. On the 7th of September, 1631, Gustavus gained the celebrated battle of Leipzig, in which 7000 Imperialists lay dead on the field of battle; 4000 were taken prisoners; a fine train of artillery was lost, and upwards of 100 standards, ensigns, and other military trophies. On this occasion the Scottish regiment in the Swedish service first practised the method of firing in platoons; to which some ascribe the astonishment and confusion that appeared in the Imperial army.

Gustavus next penetrated into Franconia, where he reduced the fort of Workburg and other places. Tilly having collected his scattered troops, which formed an army still superior to that of Gustavus, marched to the relief of this place; but came too late. He then directed his march towards Rottenberg, where four regiments were cut in pieces by a Swedish detachment. After this the king reduced Hanau, Frankfurt on the Maine, and Mentz; destroying a body of Spaniards, who had thrown themselves in the way to obstruct his passage. The court of Vienna was now thrown into the utmost confusion; and sent every where begging assistance, and soliciting the Catholic princes to arm in defence of their religion. The emperor was most embarrassed in

finding out a general capable of opposing Gustavus in the field; for the late misfortunes of count Tilly had entirely sunk his reputation. Wallestein, an old experienced officer, was made choice of; but, as he had formerly been disgraced, it was apprehended that he would not accept of the command; yet he not only accepted, but, at his own expense, augmented the army to 40,000 men. During the whole winter the Swedish army kept the field; and before the approach of summer had reduced Crantzach, Bobenhausen, Kirchberg, Magdeburg, Gozlar, Northeim, Göttingen, and Dunderstadt; while the landgrave William made great progress in Westphalia. Gustavus Horn was repulsed before Bamberg; but soon had his revenge, by entirely destroying two regiments of Imperialists. The king now resolved to give battle to Tilly, who was marching into Bavaria to prevent the Swedes from gaining a footing in that electorate. He pursued the imperial general through a vast tract of country, defeated his rear-guard, and, having reduced many towns and fortresses on the Danube, penetrated as far as Ulm. Advancing to the river Leck, count Tilly posted himself in a wood on the opposite side, to dispute his passage. Gustavus endeavoured to dislodge him by a regular fire from seventy pieces of cannon. The slaughter was dreadful; and Tilly himself, being wounded by a cannon-ball in the knee, died a few days before he was to have been superseded by Wallestein. The following night the imperial army evacuated the post; part retiring to Ingoldstadt and others to Newburg. Gustavus immediately crossed the river, and seized the towns of Rain and Newburg, which the enemy had abandoned. Augsburg next submitted; and from the inhabitants of this place Gustavus exacted an oath of fidelity, not only to himself but to the crown of Sweden. This measure gave the greatest offence to many of the Germanic body, and made them imagine that the king of Sweden had other views than the defence of the Protestant cause. From Augsburg the Swedes advanced towards Ratisbon: but were disappointed in their design of getting possession of that city, by the Bavarians having thrown a very numerous garrison into the place. In the mean time ambassadors arrived from Denmark, offering the mediation of that crown for obtaining a lasting peace. Gustavus, however, replied that no such peace could take place till the Catholic princes thought proper to grant the Protestants full and ample security for their enjoyment of future tranquillity. But the ambassadors had no instructions to propose any thing farther. Gustavus now, resolving to retort upon the Bavarians the cruelties they had inflicted on the Protestants, laid the towns of Morzbourg, Frielengen, and Landshut, in ashes. The inhabitants of Munich saved themselves by submission; but, as the peasants in that neighbourhood had collected themselves into bodies to murder the stragglers from the Swedish army, Gustavus burnt their houses, and defeated the forces of the elector, who had been joined by a body of militia. While Gustavus was thus employed Wallestein had assembled a vast army. He was solicited by the elector of Bavaria to come to his assistance; but, in

revenge of the elector's having formerly obtained the command for count Tilly in preference to himself, he drew off towards Bohemia to encounter the Saxons. Arnheim, who commanded the Saxon forces in that place, was the enemy of Gustavus, who had formerly rallied him for his cowardice. He therefore permitted Wallestein to gain an easy victory, in hopes that his master the elector of Saxony, a prince entirely devoted to his pleasure, might be induced to relinquish the friendship of such a restless and warlike ally as Gustavus; and, indeed, he used all the eloquence of which he was master to detach him from the Swedish cause. Several advantages, in the mean time, were gained by the imperialists. Pappenheim defeated the archbishop of Bremen's cavalry at Warden; and three Swedish regiments were cut off near Kadingen. Pappenheim, however, was forced to withdraw his forces from Stade; of which the Swedes took possession. Wallestein and the elector of Bavaria, who had now joined their forces, threatened Gustavus with greatly superior numbers. At last, however, the king, being reinforced with 15,000 men, no longer declined the engagement; but Wallestein was too wise to trust the fate of the empire to a single engagement against such an enemy as the king of Sweden. Gustavus attacked his camp, but was repulsed with the loss of 2000 men; which caused a general murmuring against his rashness. Several other misfortunes happened to the Swedes; and, at last, after various manœuvres, Wallestein bent his course towards Misnia, to oblige the elector of Saxony to declare against the Swedes, and to draw them out of Bavaria. Gustavus, notwithstanding the inconstancy of Augustus, immediately set out to assist him. With incredible speed he marched to Misnia, where the imperialists were assembling their whole strength. Hearing that the enemy were encamped at Wesenfels, and that Pappenheim had been detached with a strong corps, Gustavus resolved to engage them before they could effect a junction. With this view he marched to Lutzen, where he attacked Wallestein with incredible fury. The Swedish infantry broke the imperialists in spite of their utmost efforts, and took all their artillery. The cavalry not being able to pass the river so expeditiously as the king thought it necessary, he led the way, attended only by the regiment of Smaland and the duke of Saxe-Lauenburg. Here, after charging impetuously, he was killed, as Puffendorff alleges, by the treachery of the duke; who, being corrupted by the emperor, shot him in the back during the heat of the action. The news of his death was in an instant spread over both armies. The courage of the imperialists revived, and they now made themselves sure of victory. But the Swedes, eager to revenge the death of their beloved monarch, charged with such fury that nothing could resist them. The imperialists were defeated a second time, just as Pappenheim, with his fresh corps, came up to their assistance. On this the battle was renewed, but the Swedes were still irresistible. Pappenheim was mortally wounded, and his army finally routed, with the loss of 9000 killed in the field and in the pursuit.

To the treaty of Westphalia.—The victory of Lutzen proved more unfortunate to Sweden than the greatest defeat. The crown devolved upon Christina, an infant of six years old; the nation was involved in an expensive foreign war, without any person equal to the arduous task of commanding the armies or regulating domestic affairs as Gustavus had done. However, Christina, the daughter of Gustavus, was immediately proclaimed queen. The regency devolved on the grand bailiff, the marischal, the high-admiral, the chancellor, and the treasurer of the crown. Oxenstiern was invested with the chief management of affairs, and conducted himself with the greatest prudence. He was greatly embarrassed indeed by the divisions among the Protestant princes, which became more violent after the death of Gustavus; but, in spite of all difficulties, he went on pursuing the interest of his country, and planning the means of retaining the Swedish conquests. Matters went on pretty successfully till 1634, when, through the rashness of the Swedish soldiers, they were defeated at Nordlingen, with the loss of 6000 men killed, a number of prisoners, and 130 standards taken by the enemy. Oxenstiern's constancy was shaken by this dreadful blow; but he applied himself diligently to repair the loss by recruiting the army and rendering the allies faithful. The latter proved the most difficult task. The death of Gustavus, and the defeat of Nordlingen, had thrown them into despair; and every one was desirous of making the best terms he could with the emperor. The Saxons not only renounced their alliance with Sweden, but openly commenced war against it; and though the regency would gladly have consented to an honorable peace, the enemy were now too much flushed with success to grant it. Oxenstiern had no other resource than an alliance with France and the bravery of his generals. In 1635 he went in person to the court of Louis XIII. and concluded a treaty, which, however, was never observed. The enemy, in the mean time, pushed their good fortune. They surprised Philipsburg, where the French had laid up vast magazines; and reduced Spire, Augsburg, Treves, Wurzburg, Cobourg, and some other places. To complete the misfortunes of Sweden it was expected that the Poles would immediately invade Prussia. To prevent this La Gardie was despatched thither with a powerful army; but, as it was impossible to resist so many enemies at once, the chancellor purchased the friendship of Poland for twenty-six years by ceding that duchy to the republic. Thus he got rid of a powerful enemy; and the Swedish affairs began to revive by a victory which general Bannier gained over the Saxons, in consequence of which they were driven beyond the Elbe. Early in spring 1636 the Saxons made some motions as if they intended to cut off Bannier's communication with Pomerania. This he prevented by a stratagem, defeated a body of the enemy, and obliged the Saxons to retire. Soon after this he drove them out of their winter quarters with considerable loss; at which time also a considerable body of imperialists who came to their assistance were dispersed. In Westphalia general Kniphausen beat the imperialists with the

loss of 1500 men, but he himself was killed in the pursuit, and his army obliged to repossess the Weser. Some advantages were also gained in the neighbourhood of Minden by general Lesly, who had assembled a considerable army. In Alsace, Bernard, duke of Saxe-Weymar, defeated count Gallas the imperial general and dispersed his army. But when every thing seemed thus successful for the Swedes, the city of Magdeburg, contrary to the expectation of every body, surrendered for want of powder, which the garrison had wantonly consumed. The Saxons also made some conquests on the Elbe, which obliged Bannier to recall general Lesly from Westphalia to march against them. The Saxons fixed on a most convenient situation, where they hoped to destroy the Swedish army without coming to a battle. But Bannier, resolving to hazard every thing rather than suffer his army to be wasted by famine, advanced towards Berleberg, a place closely blocked up by the enemy. Here he drove from an advantageous post four regiments of Saxon curassiers, having killed or taken prisoners 400 men; after which he soon forced them to a general engagement. The numbers were very unequal, Bannier's army amounting to 9000 horse and 7000 foot, and the Saxons to 15,000 horse and thirteen battalions of foot. The battle began with great fury; the right wing of the Swedes was almost oppressed by numbers before the left could come to their assistance. They were ten times driven back, and as often returned to the charge. At last they made such a desperate effort that the enemy were entirely defeated; 5000 killed on the spot, 3000 wounded, and as many taken prisoners, with 150 standards, and several pieces of cannon.

This ended the campaign of 1636, in a manner highly honorable to the Swedes. Some fruitless negotiations were set on foot during the winter; but these coming to nothing Bannier quitted his winter quarters very early in the season; and falling upon eight regiments of Saxons cantoned at Eulenburg pursued them to Torgau, where he obliged them to surrender at discretion. Another party of Saxons was defeated near Leipzig; which he proposed investing, but was disappointed by the imperialists penetrating into Thuringia. He then called in all his detachments; defeated 2000 imperialists near Pegau, and destroyed several detachments that attempted to obstruct his march. Yet he still found his situation every day more straitened from the continual increase of the enemy's forces; which obliged him at last to retreat into Pomerania, out of which he soon drove count Gallas. The affairs of the Swedes were now once more on the brink of ruin through the misconduct of general Wrangel, who had also an army in Pomerania, but who, imagining himself perfectly secure, cantoned his troops, and extended his quarters, to accommodate his army. But Gallas suddenly returned, ravaged all Upper Pomerania, and reduced the towns of Usedom, Derrmin, and Wollin; after which, leaving garrisons in the forts, he returned to his winter quarters in Saxony. This unfortunate campaign counterbalanced all the advantages of the former. Wrangel was so struck with the suddenness of the

blow that he could take no measure for opposition. Some of the Swedish allies again fell off, and took up arms against them. In 1638 the Swedish affairs again began to revive in this quarter, through the excellent conduct of Bannier, who defeated count Gallas with the loss of 3000 men killed and taken prisoners. Pursuing his good fortune, he so harassed the count that he obliged him to repossess the Elbe and take shelter in Austria.

Great as Bannier's exploits had been, however, they were eclipsed by those of Bernard duke of Saxe-Weimar. That general had so increased his army in the Protestant cantons of Switzerland, and in Franche Comte, that he was in a condition to act without the assistance of the French, who indeed were but treacherous allies. Advancing to the Rhine he seized on Seckingen and Lassuburg, and laid siege to Rheinfeld. The imperialists, in conjunction with the troops of Bavaria, advanced to the relief of the place. An engagement ensued in which the victory was disputed; the enemy threw succors into the city, and the duke withdrew his army. Within a month he gave them battle a second time; and so completely defeated them that only one imperial officer above the rank of a captain escaped being killed or taken prisoner. He then renewed the siege of Rheinfeld, which he reduced, as well as several other important places. Advancing to Brisac he blocked it up to force the garrison to surrender. General Gotz, with 12,000 men, attempted to throw in 1000 waggons of provisions; but he was defeated with the loss of all his men except 2500. Duke Charles of Lorraine, with 4000 men, joined the remains of Gotz's army, but being surprised by Bernard his whole army was cut in pieces. A third attempt was made by Gotz, but it proved as unsuccessful as the former; and the place being reduced to great straits was obliged to capitulate. In January, 1639, the two victorious generals Bernard and Bannier prepared to attack the enemy on their own ground. Bannier made an irruption into Anhalt and Halberstadt. Leaving his infantry he pushed on with his cavalry, and surprised Salis, grand-master of the imperial artillery. After a bloody conflict the Swedes gained a complete victory, seven regiments of the enemy being cut to pieces. Next entering Saxony he defeated four regiments of the enemy, obliging a much larger body to take shelter under the cannon of Dresden. Hearing that the Saxons were encamped near Chemnitz, where they waited to be joined by the imperialists, he attacked them before this junction could be effected, and the Saxons were almost all killed or taken. Bannier next entering into Bohemia laid the country under contribution; after which, returning across the Elbe, he fell on general Hofskirk, who was encamped near Brandeiz with ten regiments of horse and several battalions of foot. Him he defeated with the loss of 2000 men. The remains of the imperial forces were pursued to the walls of Prague, and the generals Hofskirk and Montecuculi were taken prisoners. Yet notwithstanding these successes the enemies of Bannier multiplied daily. The Protestant princes, overawed by the enemy, did

not send him assistance. Undismayed, however, by difficulties, Bannier performed wonders. He defeated a body of imperialists at Giatz; drove the Saxons thence from their camp at Firn, and yet was forced to evacuate the place because he could not spare a garrison. His army being destitute of recruits was much diminished in number; yet with it he reduced many towns, and obtained various other important advantages, when on a sudden all his hopes were blasted by the death of the duke of Saxe-Weymar; poisoned, as was supposed, by the French, who wished to get Brisac into their hands, from which the duke prevented them.

The difficulties to which Bannier was now reduced proved extreme. Louis XIII. took upon him to dispose of the army and conquests of Bernard as he thought proper. Brisac, and other places of importance, he kept to himself; after which the French endeavored to ruin the army. In the mean time the imperial army under Piccolomini, in the Netherlands, was prodigiously augmented; and the archduke Leopold William, as generalissimo, was assembling his whole strength to crush the Swedes at once. But Bannier did not despair. George duke of Lunenburg, being disgusted at the emperor, Bannier hoped to gain him over; he therefore approached nearer to his country, and also drew towards the armies of Weymar and Hesse. In his way he cut in pieces a body of 3000 Croats. General Konigsmark routed the imperialists at Gera; a second time at Scholen; and a third time entirely defeated them near Leipsic. Bannier was very pressing on the allies to join him; and at last, in 1640, he was joined by the Weymar army under the dukes of Longueville and Gubrien, a body of Russians led by general Melander, and the troops of Lunenburg commanded by general Klitzing. The army now amounted to twenty-two battalions of infantry and 22,000 horse; so that they were much more than a match for their enemies, had they been under the sole direction of Bannier. But unanimity was wanting; every one would be supreme, and Bannier, the best general, had the least influence. Instead of those masterly strokes by which the Swedes had hitherto distinguished themselves, the armies continued looking at one another, each suffering the rigors of famine. At last Bannier, resolving to expose his troops no longer, set out for Thuringia, through Franconia, to seize an advantageous post on the Maine; but, as he advanced to the Sala, he found the imperialists entrenched on the other side. Finding it impossible to force a passage, he took the road through Hesse, where his troops suffered greatly by famine. Here he proposed to fight the enemy; but the Landgrave and duke of Lunenburg refused their consent. Upon this he threatened to leave them to the mercy of the confederates, and thus obliged them to be somewhat more pliant. None of those brilliant successes, however, now attended the operations of the Protestant allies; the campaigns of 1640 and 1641 were spent in useless marches and counter-marches; serving only to bring the army into the greatest dangers, from which they were as constantly relieved by the active and intrepid Bannier. At last this brave general, worn out with per-

petual fatigues, died of a fever in 1641, leaving the Swedish army in a worse situation than ever.

The imperialists were too well acquainted with the abilities of Bannier not to take advantage of the opportunity offered by his death. A Swedish detachment was cut in pieces at Quedlinburg. The Swedish army, accustomed only to be obedient to Bannier, became mutinous, and Piccolomini resolved to fall upon them with his whole force. But the four generals, Wrangel, Konigsmark, Witttemberg, and Pful, having convinced the soldiers of the necessity of defending themselves, made such excellent dispositions that the imperialists durst not attack them. Piccolomini then detached part of his army to attack the Hessians in their quarters; but Wrangel and Konigsmark threw themselves in their way, and defeated them with the loss of 2000 men. This victory, however, did not retrieve the Swedish affairs. Dissensions and mutiny began again to take place in the army to such a degree as threatened its dissolution. In 1642 general Torstenson was sent from Sweden with money, and a strong reinforcement, to take upon him the supreme command. This general was inferior to none of his predecessors, and designed to come to an immediate engagement; but the Weymar army separating from him obliged him to remain for a considerable time inactive. He was also confined to his chamber by the gout; and thus, a report of his death being spread, the imperialists were encouraged to begin a long march through roads scarcely passable, in hopes of surprising the Swedish army without a general. But Torstenson seized an advantageous post, which could not be forced, and thus obliged the enemy to retreat, after having suffered as much by their fatiguing march as if they had fought a bloody battle. Then joining general Stalhanch, who had been driven by the imperialists out of Silesia, he reduced Great Glogau, with a number of other important places; after which he laid siege to Schweidnitz. The duke of Saxe Lauenburg, with his cavalry, endeavoured to throw in succors; but was defeated with the loss of 3000 men, taken prisoner, and died of chagrin a few days after. In consequence of this defeat Schweidnitz surrendered at discretion; and Torstenson, having sent a detachment to invest the city of Neisse, proceeded with the rest to drive the enemy entirely out of Silesia. This he effectually performed, obliging them to retire over barren mountains, almost famished for want of provisions, and harassed by his light troops; so that this lately formidable army was almost entirely ruined. With his victorious troops the Swedish general then poured into Moravia; where in five days he reduced the strong town of Olmutz.

Litta and Neustadt shared the fate of Olmutz; after which the Swedes, returning suddenly to Silesia, took Oppelen and Brieg, and laid siege to Breslau. Here the garrisons made such an obstinate defence that the imperialists had time to assemble under the conduct of the archduke Leopold, and come to their relief. As Torstenson was greatly inferior in number, he raised the siege; but appeared so formidable in his retreat that the enemy durst neither attack him, nor attempt

to prevent his encamping in a very advantageous situation. The imperialists then laid siege to Glogau; but, after having lost a great number of men, they were forced to abandon the enterprise on the junction of Wrangel with Torstenson; by which means the Swedes were once more in a condition to face their enemies in the field. Torstenson now projected an irruption into Bohemia, but in this he was prevented by the vigilance of the enemy: however, he reduced the city of Zittau, where for the first time a cartel for prisoners was established; by which means the Swedish army was considerably augmented. Torstenson then directed his course to Leipsic, but the imperial generals assembled their whole force, and set out to relieve it. The two armies soon came in sight of each other; and the Swedes, after an obstinate conflict, obtained a complete victory, 5000 of the enemy being killed on the spot, 3000 wounded, and as many taken prisoners. This victory was followed by the immediate surrender of Leipsic.

In all probability the Swedes would have finally triumphed over all their enemies, had not a rupture with Denmark ensued. Torstenson and Horn behaved with their usual valor in Holstein and Schonen, while general Konigsmark distinguished himself in Germany; but the ruin of the Weymar army, which was totally defeated with the loss of one half its number at Dettingen by the Bavarians, proved a dreadful blow, from which the Swedes could scarcely recover themselves. Indeed, notwithstanding the valor and success of the Swedes, their affairs in Germany must have gone to wreck in the campaigns of 1643 and 1644, had not the French under Condé and Turenne made a most powerful diversion, and performed such exploits as immortalised their names. In 1645 the war against Denmark was pushed with such vigor that a peace, very advantageous for Sweden, was concluded. Torstenson now took measures for carrying the war into the Austrian dominions. Hatfield assembled a considerable army to oppose the Swedes; and the emperor came to Prague to animate his troops. The two armies came in sight at Jancowitz, and prepared for an engagement. The valor of the Swedes once more prevailed, and they totally defeated their enemies: 4000 of the imperialists were killed on the spot, among whom were general Hatfield and many officers; and nearly 5000 were taken prisoners. Yet no great advantages were derived from this victory. Some towns indeed were reduced: but at last Torstenson was obliged to retire into Moravia, where he put his army into winter quarters; and, in the beginning of 1646, resigned the command to Wrangel. Wrangel conducted the Swedish affairs with great ability and success; till at last the imperialists, unable to drive the Swedes out of Germany, concluded a peace in 1648. This was the memorable treaty of Westphalia, by which the Germanic constitution was settled, and those disputes which had so long torn the empire were ended: the duchies of Bremen and Verden, all the Upper and part of Lower Pomerania, the city of Wismar and the isle of Rugen, were assigned to Sweden, and 5,000,000 of crowns were given to the army.

Sweden to the death of Charles X.—Sweden

now enjoyed some years of repose. Charles Gustavus, count palatine, having gained the favor of Christina, was appointed generalissimo of the forces, and heir apparent to the crown. A marriage was proposed between them; but the queen would never listen to this or any other proposal of the kind. In 1650 the ceremony of the queen's coronation was performed; but in 1654 she resigned the crown in favor of Gustavus. See CHRISTINA.

Charles Gustavus, who now took the name of Charles X., found himself involved in considerable difficulties on his accession. The treasury was quite exhausted; great part of the revenue was appointed for the support of Christina's household; the people were oppressed with taxes; the nation, having been disarmed for several years, began to lose its reputation. To remedy these evils, Charles proposed to resume all the crown lands which had been alienated to favorites during the late reign; to repeal the duty upon salt; to put the kingdom in a posture of defence; and to enter upon a war with some neighbouring state. Under pretence that Casimir king of Poland had questioned his title to the throne, he prepared to invade that kingdom. Several embassies were sent from Poland to Stockholm; but they returned without their errand. General Wittemberg made an irruption into Poland from Pomerania. The Poles opposed him with an army of 15,000 men, but in a short time they entirely dispersed themselves. Charles, with a powerful army, pursued his march, all the cities throwing open their gates to him. As he advanced to Cracow, Casimir made one effort to save his capital. But his army amounted only to 10,000 men; and these, after a feeble resistance, fled with precipitation, having lost 1000 men in killed and prisoners. A few days after this, Charles defeated the Poles a second time about twenty-four miles from Cracow; upon which Casimir fled with his family to Oppelen, in Silesia. The capital was then invested; and, though defended with the utmost valor by Stephen Czarneski, was soon obliged to capitulate. Thus, in less than three months, Charles apparently became master of Poland; but the Poles had no intention of abandoning their former sovereign.

In 1656 a war took place with the elector of Brandenburg. While Charles was employed in the conquest of Poland, that prince had invaded the Royal and Ducal Prussia, and reduced the most considerable towns. The king of Sweden marched against him, defeated his forces in several slight encounters, and obliged him to own that he was a vassal of Sweden. These rapid conquests alarmed all Europe; and the different powers sought for means of driving the Swedes out of Poland, which they had so unjustly seized. The Poles, assured that they should be assisted, every where revolted and massacred the Swedes. Casimir returned from Silesia; and those troops and generals who had submitted to Charles now ranged themselves under his antagonist. Charles immediately marched for Prussia, and totally defeated 12,000 Poles under Czarneski. This did not hinder all the Poles incorporated with his troops to desert; which reduced his army: and, the campaign being performed in the depth of winter, he was

obliged to retreat to Prussia. In his march he was harassed by the Poles; and a body of 4000 Swedes was defeated by them at Warka. But this loss was soon after compensated by a complete victory gained by Adolphus the king's brother, and general Wrangel, over Czarneski. In the mean time Charles took measures for laying siege to Dantzic; but the Dutch threatened to oppose him, unless a proper regard was paid to their interest. Charles accordingly granted them advantageous terms; and afterwards gained over the elector of Brandenburg, by ceding to him the sovereignty of Prussia, that he might be at liberty to turn his whole strength against Poland. By the treaty with the elector, the latter was to assist Charles in his war with Poland; but the elector had so procrastinated matters, that the Poles, having obtained assistance from the Tartars, had reduced the city of Warsaw. The two princes however now marched in concert against their enemies, who were encamped in a strong situation near Warsaw, their camp being fronted by the Vistula. The Poles were driven from their entrenchments with prodigious slaughter, and a vast number taken prisoners. The Poles and Tartars then labored to break the alliance; entered Ducal Prussia, and defeated the electoral army, taking prince Radzivil and other great persons prisoners. The Swedes soon had their revenge. General Steinboek attacked the Polish army at Philippowa, and overthrew it with such slaughter as obliged the Poles to quit the field. A more formidable enemy than the Poles now began to appear. The Russians invaded the provinces of Carelia, Ingermania, and Livonia, while the elector of Brandenburg began to waver in his fidelity. To preserve this only ally at such a critical juncture, Charles was obliged to give him more advantageous terms; while the Russians were repulsed in Carelia and Ingermania. But in Livonia they had better success, two important fortresses falling into their hands; after which they laid siege to Riga. For seven months they battered the walls of this city, without once venturing to pass the ditch or storm the practicable breaches. The besieged, under Magnus de la Gardie and Simon Helmfield, defended themselves with the greatest intrepidity, cutting off many thousands of the enemy in the sallies they made. At last they attacked the Russian camp, drove them out of it with great slaughter, and obliged them to raise the siege with precipitation.

Charles, notwithstanding the number of his enemies, was now become so formidable by the valor of his troops that whole armies often fled on the very news of his approach. At last, in 1657, the Poles, finding they could not resist him in the field, harassed the Swedes on their march, and cut off the foragers and convoys. This proved much more destructive to the Swedes than their former method; so that Charles was obliged to enter into an alliance with Ragotski prince of Transylvania, by assigning him certain provinces in his neighbourhood, to furnish himself with irregular troops, who might fight the Poles in their own way. But the confederates, after spending a whole campaign in Lithuania, were obliged to return without accomplishing

more than the reduction of a single fortress; upon which Charles returned with the Swedish army to Prussia. Leopold, the young king of Hungary, having beheld for a long time the Swedes with a jealous eye, resolved to declare for Poland. To curb the ambition of the Swedish monarch he solicited the king of Denmark to break with him. This was complied with, and the Danes invaded Bremen. Charles hastened to oppose this new enemy; which gave such offence to Rogotski that he neglected to take proper measures for his own defence in the absence of the Swedes, and suffered his army to be destroyed by the Poles and Tartars. At the same time the Turks invaded Transylvania, under pretence that Rogotski, being a vassal of the grand seignior, had no right to invade Poland without his leave. Rogotski opposed them in the field; where he was defeated and killed, leaving Charles destitute of the only ally on whom he could have depended. But, not dismayed by this misfortune, he traversed Pomerania and Mecklenburg; after which he fell upon Holstein, while general Wrangel with another corps entered Bremen. In fifteen days Wrangel retook all the towns which the enemy had reduced; defeated and drove the Danish army out of the country, killing 3000 of their best soldiers. In Holstein the king reduced several fortresses, laid Itzehoe in ashes, defeated a body of Danes, and laid siege to Frederic Udda, into which the Danes had thrown a strong garrison. The conduct of this siege he left to Wrangel, he himself retiring to Wismar to observe the situation of Poland; but no sooner was he gone than Wrangel attacked the place with such fury that he became master of it in two hours. In Holland the Swedes were defeated; but the enemy derived no advantage from their victory: at sea the fleets met and maintained a hot engagement for two days, without any considerable advantage on either side. In Poland matters went on much worse. The house of Austria had now declared for Casimir; a German army entered Poland and reduced Cracow, though not without great loss. Czarneski entered Pomerania, where he butchered the unhappy peasants; but on the approach of Charles he fled as usual, having gained nothing by his expedition but the character of a cruel barbarian. The king of Sweden was now surrounded by enemies. The elector of Brandenburg had declared against him; and he had besides to engage the armies of Austria, Poland, Russia, and Denmark in the field. In this dangerous situation he resolved to attack Denmark in such a manner as should oblige that power to come to a speedy accommodation. His designs were forwarded by a very early frost which enabled him to transport his troops without shipping. Having passed over on the ice to the island of Funen, he cut in pieces a body of 4000 Danish soldiers and 500 peasants. The whole island was reduced in a few days; after which he passed to Langland, then to Laaland, after that to Falstere, and lastly to Zealand. The Danes were terrified at this unexpected invasion, and were giving themselves up to despair, when Charles offered peace upon equitable terms. The king of Denmark very gladly consented. By this treaty, called the

treaty of Roschild, concluded 12th March 1658, the provinces of Schonen, Halland, and Bleking, Lyster, and Huwen, the isle of Borkholm, the bailliages of Bahus and Drontheim in Norway, were yielded to Sweden, and a free passage through the sound was granted to the Swedish ships.

No sooner was Charles retired than the king of Denmark began to act against him in an underhand manner; on which, resolving to anticipate him in his design, he appeared unexpectedly with a fleet before Copenhagen. Had he given the assault immediately, before the inhabitants had time to recover from their surprise, it would probably have surrendered at once; but, by landing at the distance of seventeen miles, he gave them time to prepare for their defence: the siege proved extremely tedious, and at last the place was relieved by a Dutch fleet. On this Charles converted the siege into a blockade, which continued till the end of the war. Wrangel reduced the strong fortress of Gronenburg; and the Swedish forces were so judiciously posted that all Denmark was in a manner blocked up; when in 1660 king Charles X. died of an epidemical fever: and thus an end was put for that time to all the ambitious designs of Sweden.

To the imprisonment of Charles XII. in Turkey.
—The new king Charles XI. was a minor at his father's death; and, as the kingdom was involved in a dangerous war with so many enemies, the regency determined to conclude a peace, if it could be obtained on reasonable terms. A treaty was accordingly concluded at Oliva: by which Casimir renounced his pretensions to the crown of Poland, and that republic gave up all pretensions to Livonia. Bornholm and Drontheim were ceded to Denmark; and an equivalent in Schonen remained with Sweden. During the minority of the king nothing remarkable occurred. In 1672 he entered into alliance with Louis XIV.; which, in 1674, involved him in a war with the elector of Brandenburg. At first the Swedes carried all before them; and, general Wrangel having fallen sick, they continued their conquests under Mardenfeldt. Almost all the towns in Brandenburg were reduced when the elector arrived with an army. He retook several towns, defeated Mardenfeldt in a general engagement, and soon after forced them to abandon all their conquests. In conjunction with the Danes, he then invaded the Swedish dominions: many places of importance were reduced; and in 1676 Sweden received a most destructive blow by the defeat of her fleet in an engagement with the combined fleets of Denmark and Holland. Soon after this the king took the government into his own hands, and in some degree restored the fortune of Sweden; but, though matters went on in a prosperous way where the king commanded in person, the same disgrace attended the Swedish arms in every other quarter. In Pomerania count Konigsmark lost every part of importance excepting Stralsund, Stetin, and Gripswald. In 1678 the Swedish fleet was defeated in two engagements. At Landscreon a most obstinate battle was fought from 10 A. M. till 6 P. M., when both parties were obliged by fatigue to retire to their camps. At Oldeval, in Norway, the

Swedes were defeated; and the Danes laid desolate the islands of Oeland, Smaland, Unno, and Kuno; while the electoral troops and Imperialists reduced count Königsmark to the utmost distress near Stralsund. But in this deplorable situation count Königsmark attacked his enemies to such advantage that he obtained a complete victory; after which he ravaged the duchy of Mecklenburg. Yet he could not prevent the elector from reducing Stralsund; after which he was obliged to evacuate Pomerania; and, to complete his distress, the fleet which transported the Swedish army from Pomerania was wrecked on the coast of Bornholm; by which accident 2000 persons were drowned, and the remainder plundered and taken prisoners by the Danes, though they had been furnished with passports from king Frederic. In this unprosperous situation of affairs a peace was concluded at St. Germain's with France, by which the Swedes and Danes were left to decide their quarrel by themselves. Denmark being no match for Sweden, even in her distressed situation, a treaty was soon concluded on terms very favorable to Sweden; and confirmed by a marriage between Charles and Ulrica Eleonora, daughter to the king of Denmark. From this time the Swedish monarch applied himself to the reformation of the state; and, by artfully managing the disputes between the nobility and peasants, he obtained a decree of the states empowering him to alter the constitution as he pleased. Being thus invested with absolute power, he proceeded to take some very extraordinary measures. In 1685 it was projected to liquidate the public debts by raising the nominal value of money, without adding any thing to its intrinsic value. This was put into execution in 1686, by which the creditors of the government lost upwards of 9,000,000 of crowns. This, with some other arbitrary steps, disgusted all the nobility, merchants, and crown creditors. In Livonia they were highly resented; and remonstrances were repeatedly sent by the hands of deputies, who had orders to insist upon their privileges, confirmed by many acts of the king's predecessors. The deputies could obtain nothing, so that the diet was assembled. On their report the nobility resolved to draw up a stronger remonstrance than any of the former, to be presented to the king by captain Patkul, one of the deputies, who had already distinguished himself by his boldness and attachment to liberty. His public spirit, however, produced no other effect than to procure his own destruction. See PATKUL. On the 15th April, 1697, died Charles XI., leaving his crown to his son, the celebrated Charles XII., then a minor.

Charles XII., on his accession, was only fifteen. He was scarcely seated on the throne when a powerful combination was formed against him. Augustus, king of Poland, formed designs on Livonia; Christian V. of Denmark revived the disputes with the duke of Holstein, as a prelude to a war with Sweden; and Peter the Great of Muscovy began to form designs upon Ingria, formerly a province of Russia. In 1699 Christian marched an army into Holstein; Charles sent troops to the duke's assistance; but before their arrival the Danes had ravaged the

country, taken the castle of Gottorp, and laid siege to Tonningen. Here Christian commanded in person; and was assisted by the troops of Saxony, Brandenburg, Wolfenbuttle, and Hesse-Cassel. England and Holland as guaranties of the last treaty with Denmark, in concert with Sweden, joined Charles against this confederacy, and sent fleets to the Baltic. They proposed a termination of the war upon equitable terms; but these were haughtily refused by the Danish monarch, who despised the youth of Charles, and relied upon his alliance with Saxony, Brandenburg, Poland, and Russia. The town of Tonningen, however, resisted all his efforts; and, when he ordered the place to be stormed, his troops were driven headlong from the walls by a few Swedes under general Bannier. In 1700 Charles, having entrusted the affairs of the nation with a council chosen out of the senate, set out on the 8th of May from his capital, to which he never afterwards returned. He embarked at Carlscroon, and defeated the fleet of the allies. Having made a descent on Zealand, he defeated a body of cavalry, and proceeded to invest Copenhagen by sea and land. Frederick IV., the new king of Denmark, saw the danger of having his capital destroyed, and concluded a treaty in eleven days, upon the same terms as the former. Charles, being thus at liberty to turn his arms against the other princes, resolved to lead his army against Augustus king of Poland; but, hearing that the czar had laid siege to Narva with 100,000 men, he immediately embarked at Carlscroon, though it was then mid winter, and the Baltic scarcely navigable; and soon landed at Pernaw in Livonia with part of his forces. His army did not exceed 20,000 men; but they were the best soldiers in Europe, while the Russians were only an undisciplined rabble. The consequence was, the Swedes were victorious, entirely routing this vast army, and taking all the cannon, 20,000 prisoners, and entirely destroying the remainder.

Peter was advancing with 40,000 men to surround the Swedes, when he received intelligence of the dreadful defeat at Narva. He was greatly chagrined; but returned to his own dominions to raise another army. He evacuated all the provinces which he had invaded, and for a time abandoned all his great projects, thus leaving Charles at liberty to prosecute the war against Poland. As Augustus had expected an attack, he endeavoured to draw the czar into a closer alliance with him. The two monarchs had an interview at Birsén, where it was agreed that Augustus should lend the czar 50,000 German soldiers, to be paid by the czar, who should send an equal number of his troops to be trained up to war in Poland; and that he should pay the king 3,000,000 of rixdollars in two years. Of this treaty Charles had notice, and, by means of his minister, count Piper, entirely frustrated the scheme. In 1701 Charles, having received a reinforcement from Sweden, took the field, and appeared suddenly on the banks of the Duna, along which the Saxon army was posted to receive him; he gained a signal victory.

This victory was followed by the surrender of all the towns and fortresses in the duchy of Cour-

land. The king then passed into Lithuania, where every town opened its gates to him. At Birsen an army of 20,000 Russians retired with precipitation on his approach, when Charles, perceiving that Poland was greatly disaffected to Augustus, began to project the scheme of dethroning him by means of his own subjects. While count Piper was intriguing with the Poles for this purpose, Augustus determined to trust his fortune to the Saxon army and the nobility of Cracow, who offered to support him to the utmost. The Saxon army was now advanced to the frontiers, and Augustus put himself at the head of it. Being joined by the nobility of Cracow, his forces amounted to 30,000 men, all brave and well disciplined. With these he marched in quest of his enemy; who did not decline the combat, though he had with him only 12,000 men. Though the Saxons were strongly posted, they were entirely defeated, with the loss of 4000 killed, 2000 prisoners, and all their baggage and cannon. This victory was followed by the loss of Cracow; after which Charles set out in pursuit of the flying army, with a design of preventing them from re-assembling; but his horse falling under him, he had the misfortune to break his thigh bone, by which he was confined six weeks; and thus Augustus obtained some respite.

Augustus made the best of this interval. Having convoked a diet first at Marienburg, and then at Lublin, from them he obtained the following resolutions: that an army of 50,000 men should be raised by the republic for the service of the prince; that six weeks should be allowed the Swedes to determine whether they were for war or peace; and that the same time should be granted to the turbulent and discontented nobles of Poland to make their concessions. To counteract the effects of these resolutions, Charles assembled another diet at Warsaw; and, while the two assemblies disputed concerning their rights and privileges, he recovered of his wound, received a strong reinforcement from Pomerania, and utterly defeated and dispersed the remains of the Saxon army. The ill-fortune of Augustus continued. In 1704 he was formally deposed by the diet, and the crown conferred by Charles on Stanislaus Lecinsky palatine of Posnania. Augustus, however, did not yet tamely give up his kingdom. His adherents daily skirmished with the Swedes, and Augustus himself, being reinforced by 9000 Russians, retook Warsaw, and was very near surprising the new king, who lived in perfect security in the city, while Charles fought in his cause. Count Horn, with 1500 Swedes, vigorously defended the citadel; but, finding it no longer tenable, he surrendered at discretion. The reduction of Warsaw was amongst the last advantages gained by Augustus in this war. His troops were now composed of Saxon recruits and undisciplined Poles, who had no attachment to his person. Charles and Stanislaus advanced with the victorious army; the Saxons fled, and the towns for several miles round sent their submissions. The Poles and Saxons were under Schulleberg, a most experienced general, who used every expedient to

check the progress of the Swedes. But, with all his conduct and caution, he found himself outwitted, and Charles near his camp, ready to fall upon him, while he thought him at fifty leagues distance. The king attacked him with a superior army, but entirely composed of horse. This was almost the first time that infantry had been regularly opposed to cavalry, and the superiority of the former was evident. After the engagement had continued about three hours, the Saxons retreated in good order; which no enemy had ever done before in any engagement with Charles. The Swedes pursued them towards the Oder, but Schulleberg effected a retreat which Charles always spoke of with admiration, and said he had been conquered by Schulleberg. No material advantage, however, resulted from this to Augustus; who was again obliged to leave Poland, and fortify the capital of Saxony which he expected every moment to see invested. In the mean time, the Russians, having recovered their spirits, fell upon the Swedes in Livonia with the utmost fury. Narva, Dorpt, and several other towns were taken, and the inhabitants and garrisons treated with great barbarity. Soon after an army of 100,000 Russians entered Poland: 60,000 Cossacks, under Mazeppa, entered the country at the same time, and ravaged every thing with the fury of barbarians. Schulleberg, too, advanced with 14,000 Saxons and 7000 Russians, disciplined in Germany, and reputed excellent soldiers. But Charles seemed to triumph over his enemies with more ease, the more numerous they were. The Russians were defeated so fast that they were all dispersed before one party had notice of the misfortunes of another. The Swedish general Renschild engaged and defeated Schulleberg in half an hour. Whole regiments of Saxons threw down their arms, and begged their lives: 6000 were slain in the field, and 7000 taken prisoners; thirty-six pieces of cannon, 11,000 muskets, forty pairs of colors and standards, with all the Saxon baggage, fell into the hands of the Swedes: and the consequences were still more important; for now a passage was opened into Saxony, and Augustus seemed to be in as great danger of losing his hereditary dominions as he had been of losing Poland. This extraordinary victory, which was gained February 12th, 1706, was looked upon with admiration, and thought to make the renown of Renschild equal to that of his sovereign. Charles himself became jealous of his fame. But the cruelty of Renschild sullied his reputation; for six hours after the engagement, he caused 1000 Russians to be massacred in cold blood, to revenge, as he said, the cruelties they had committed in Poland.

Soon after this victory, Charles entered Saxony at the head of 24,000 men. The diet at Ratisbon declared him an enemy to the empire if he crossed the Oder. But to this declaration he paid no regard, but pursued his march; while Augustus was reduced to the condition of a vagrant in Poland, where he possessed not a single town besides Cracow. Into this city he threw himself with a few Saxon, Polish, and Russian regiments, and began to erect some for-

tifications for its defence; but the approach of the Swedish general Meyerfeldt, and the news of the invasion of Saxony, disconcerted all his measures, and threw him into despair. The Russians indeed were his faithful allies; but he dreaded them almost as much as the Swedes: so that he was under the necessity of writing to Charles with his own hand, begging for peace on any terms. But, as he was then at the mercy of the Russians, this transaction was concealed with the greatest care. His emissaries were introduced to Charles in the night time; and received the following answer:—That Augustus should for ever renounce the crown of Poland, acknowledge Stanislaus, and promise never to reascend the throne, should an opportunity offer; that he should release the princes Sobieski, and all the Swedish prisoners made in the course of the war; surrender Patkul, then resident at his court as ambassador for the czar of Muscovy; and stop proceedings against all who had passed from his into the Swedish service. Augustus all this time was obliged to continue a show of war, though he had neither ability nor inclination to carry it on. He was joined by prince Menzikoff with 30,000 Russians; which obliged him, contrary to his inclination, to engage with Meyerfeldt, who commanded 10,000 men, one half of whom were Swedes. As at this time no disparity of numbers was reckoned an equivalent to the valor of the Swedes, Meyerfeldt did not decline the combat, though the army of the enemy was four times as numerous as his own. With his countrymen he defeated the enemy's first line, and was on the point of defeating the second when Stanislaus, with the Poles and Lithuanians, gave way. Meyerfeldt then perceived that the battle was lost; but he fought desperately, to avoid the disgrace of a defeat. At last, however, he was oppressed by numbers, and forced to surrender: suffering the Swedes, for the first time, to be conquered by their enemies. The whole army were taken prisoners excepting major-general Krassau; who, having repeatedly rallied a body of horse formed into a brigade, at last broke through the enemy, and escaped to Posnania.

Augustus had scarcely sung *Te Deum* for this victory, when his plenipotentiary returned from Saxony with the articles of the treaty above-mentioned. The king hesitated and scrupled, but at last signed them; after which he set out for Saxony, glad at any rate to be freed from such an enemy as the king of Sweden, and from such allies as the Russians. The czar Peter was no sooner informed of this extraordinary treaty, and the cruel execution of his plenipotentiary Patkul (see PATKUL), than he sent letters to every court in Christendom, complaining of this gross violation of the law of nations, but without effect. In 1707 he entered Poland at the head of 60,000 men. Advancing to Leopold, he made himself master of that city, where he assembled a diet and solemnly deposed Stanislaus, with the same ceremonies which had been used with regard to Augustus. The country was now reduced to the most miserable situation; one party through fear adhered to the Swedes; another was gained over, or forced by Peter to

take part with him: a violent civil war took place between the two, and great numbers of people were butchered, while cities, towns, and villages, were laid in ashes by the frantic multitude. The appearance of a Swedish army under king Stanislaus and general Lewenhaupt put a stop to these disorders, Peter himself not caring to stand before such enemies. He retired, therefore, into Lithuania, giving as the cause of his retreat, that the country could not supply him with provisions and forage necessary for so great an army. In the mean time Charles had taken up his residence in Saxony, where he gave law to the court of Vienna, and intimidated all Europe. He declared himself the protector of the Protestant interest in Germany, particularly of the emperor's Protestant subjects in Silesia. He desired, or rather commanded, the emperor to renew and confirm to them all the liberties granted by the treaties of Westphalia, but since that time reclaimed or eluded at the treaty of Ryswick. The emperor durst not refuse; and upwards of 100 churches were given to the Protestants. At last, Charles began to evacuate Saxony, in pursuit of his great plan, the dethroning czar Peter, and conquering the vast empire of Russia. While the army was on full march, in the neighbourhood of Dresden, he surprised king Augustus with a visit with only five attendants.

The armies of Sweden, in Saxony, Poland, and Finland, now exceeded 70,000 men; a force more than sufficient to have conquered all the power of Russia had they met them on equal terms. Peter, who had his army dispersed in small parties, instantly assembled it on receiving notice of the king of Sweden's march; was making all possible preparations for a vigorous resistance, and was on the point of attacking Stanislaus, when the approach of Charles struck his whole army with terror. In January 1708 he passed the Niemen, and entered the south gate of Grodno, just as Peter was quitting the place by the north gate. Charles at this time had advanced to some distance before the army at the head of 600 horse. The czar, having intelligence of his situation, sent back a detachment of 2000 men to attack him: but they were utterly defeated; and this disappointment was followed by the total evacuation of Lithuania. The king pursued his flying enemies in the midst of snow and ice, over mountains, rivers, morasses, and through almost every obstacle that could be surmounted by human power; and, coming up with them at the Boristhenes, completely defeated them.

The czar, finding himself closely pursued by the enemy with whom he was not able to cope, proposed peace; but Charles returned no other answer than that he would treat at Moscow; which being reported to Peter, he coolly replied, 'My brother Charles affects to play Alexander, but he will not find in me a Darius.' However he did not venture an engagement, but continued his retreat; and Charles pursued so closely that he was daily skirmishing with the rear of the enemy. In these actions the Swedes had generally the advantage, though in the main these victories proved detrimental, by weakening the army in a country where it was impossible to re-

cruit. Near Smolensko, the king, with only six regiments, defeated a body of 10,000 horse and 6000 Calmucks. In this engagement he was exposed to the utmost danger, the enemy having separated him from his troops.

By the 3d of October 1708 Charles was within 109 leagues of Moscow; but Peter had made the roads impassable, either by laying them under water, digging deep ditches, or covering them with the wood of whole forests. He had also destroyed the villages on every side, and taken away every possibility of subsisting an army. The season was also far advanced; the intense severe weather was approaching; so that the Swedes were threatened with all the miseries of cold and famine, at the same time that they were exposed to the attacks of an enemy greatly superior in number. For these reasons the king resolved to pass through the Ukrain, where Mazeppa, a Polish gentleman, was general and chief of the nation. Mazeppa, having been affronted by the czar, readily entered into a treaty with Charles, whom he promised to assist with 30,000 men, great quantities of provisions and ammunition, and with all his treasures, which were immense. The Swedish army advanced towards the Disna, where they had to encounter the greatest difficulties; a forest above forty leagues in extent filled with rocks, mountains, and marshes. To complete their misfortunes, they were led ninety miles out of the right way; all the artillery was sunk in bogs and marshes; the provision of the soldiers, which consisted of biscuit, was exhausted; and the whole army spent and emaciated when they arrived at the Disna. Here they expected to have met Mazeppa with his reinforcement; but, instead of that, they perceived the opposite banks of the river covered with a hostile army, and the passage itself almost impracticable. Charles, however, was still undaunted; he let his soldiers by ropes down the steep banks; they crossed the river, either by swimming or on rafts hastily put together; drove the Russians from their post, and continued their march. Mazeppa soon after appeared, having with him about 6000 broken remains of the army he had promised. The Russians had got intelligence of his designs, defeated and dispersed his adherents, laid his towns in ashes, and taken all the provisions collected for the Swedish army. However, he still hoped to be useful by his intelligence in an unknown country; and the Cossacks, out of revenge, crowded daily to the camp with provisions. Greater misfortunes still awaited the Swedes. When Charles entered the Ukrain, he had sent orders to general Lewenhaupt to meet him with 15,000 men, 6000 of whom were Swedes, and a large convoy of provisions. Against this detachment Peter now bent his whole force, and marched against him with an army of 65,000 men, Lewenhaupt defeated him in a number of engagements, and at last arrived at the camp of Charles with 4000 men, after having killed upwards of 30,000 of the enemy on their march.

This was the last effort of Swedish valor. The difficulties they had now to undergo exceed what human nature could bear; yet still they hoped by constancy and courage to overcome

every obstacle. In the severest winter known for a long time, even in Russia, they made long marches, clothed like savages in the skins of wild beasts; all the draught horses perished: thousands of soldiers dropped dead with cold and hunger: so that by February, 1707, the whole army was reduced to 18,000. Amidst numberless difficulties these penetrated at last to Pultowa, a town on the eastern frontier of the Ukrain, where the czar had laid up magazines; and of these Charles resolved to get possession. The place made an obstinate defence, the Swedes were repulsed in every assault, and 8000 of them were defeated and almost entirely cut off, in an engagement with a party of Russians. To complete his misfortunes, Charles received a shot from a carbine in his heel, which shattered the bone. For some days the czar, with an army of 70,000 men, had lain at a small distance, harassing the Swedish camp, and cutting off the convoys of provision; but now intelligence was received, that he was advancing, as if with a design of attacking the lines. In this situation, Charles determined to be the assaulter, and on the 8th of July, 1709, he lost the memorable battle of Pultowa, which decided the fate of the Swedes. Our limits forbid a detail of the particulars, but the issue of the day was, that Charles escaped with a mere handful of followers; the rest of his army being slain or taken prisoners.

Charles fled in a mean calash, attended by a little troop inviolably attached to his person, some on foot, and some on horseback. They were obliged to cross a sandy desert, where neither herb nor tree was to be seen, and where the burning heat and want of water were more intolerable than the extremities of cold they had formerly suffered. They reached Oczakow, the bashaw of which supplied the king with every necessary. But it was some time before boats could be got ready for transporting the whole of the king's attendants; by which accident 500 Swedes and Cossacks fell into the hands of the enemy. This loss affected him more than all his other misfortunes. The king remained but a few days at Oczakow, when the serasquier of Bender sent an aga to compliment him on his arrival in the Turkish dominions, and to invite him to that city. Here he was treated with the utmost hospitality. In the Turkish divan it was proposed to escort Charles with a numerous army to the frontiers of Poland: but the revolution which took place there quickly put an end to all such projects. Augustus thought himself no longer bound to observe the treaty which he had made, than Charles was at hand to force him to it. After the battle of Pultowa, therefore, he entered Poland, and took every measure, in concert with the czar, for the recovery of his kingdom. Stanislaus was obliged to leave his dominions and fly to Bender, in the disguise of a Swedish officer, to share the fortune of Charles. It was not in Poland alone that the Swedish affairs began to suffer in consequence of the defeat at Pultowa. The Danes invaded the province of Schonen with an army of 13,000 foot and 2500 horse. Only 13,000 Swedish forces remained to defend all the territories possessed by

Charles in Germany; and of these only a small part were allotted for the defence of Schonen. The regency of Sweden, however, exerted themselves to the utmost to repel this ungenerous invasion; and, having collected an army of 12,000 militia and 8000 regulars, despatched them under general Steenboek into Schonen. Some Saxon troops were incorporated in this army; and among these a prodigious desertion took place, which the general found it impossible to prevent; and thus the Danes gained several advantages, and at last took Christianstadt. Their insolence on this success was so great that the Swedes demanded to be instantly led against them. Here the good fortune of Sweden seemed once more to revive. The Danes were driven from a very strong situation, with the loss of 8000 killed and taken prisoners, besides a vast number wounded.

In the mean time Charles, by his agents, count Poniatowski and Sieur Neugebar, used his utmost efforts to procure a rupture between the Porte and Russia. For a long time the money bestowed by Peter on the viziers and janisaries prevailed; but at last, in 1711, the grand seignior, influenced by his mother, who was strongly in the interest of Charles, and who had been wont to call him her lion, determined to avenge his quarrel with Peter. He therefore gave orders to the vizier to fall upon the Russians with an army of 200,000 men. The vizier promised obedience; but professed his ignorance in the art of war. The khan of Crim Tartary, who had been gained over by the reputation and presents of the king of Sweden, had orders to take the field with 40,000 of his men, and had the liberty of assembling his army at Bender, that Charles might see that the war was undertaken upon his account. The czar, on these news, left the siege of Riga, where he had continued for some months; and with 24,000 men entered Moldavia, where he was joined by Cantemir, a vassal of the Porte. The vizier marched against him with a prodigious army; and, through the negligence of the czar, cooped him up in such a manner that he could neither advance nor retreat. In this desperate situation he perceived that he was now in as bad a situation as Charles at Pultowa; and gave orders for breaking through the enemy with fixed bayonets. The desponding spiritless soldiers, however, were little disposed to execute these orders; when Catharine, wife to the czar, without his knowledge, set on foot a treaty with the vizier; and, having soon obtained his consent, had the peace signed in six hours; by which means the whole Russian army was saved. The new treaty was most violently opposed by count Poniatowski and the khan of Tartary. The former had made the king acquainted with the situation of both armies; on which he instantly set out from Bender, filled with the hopes of fighting the Russians, and taking ample revenge. Having ridden fifty leagues post, he arrived at the camp just as the czar was drawing off his half-famished troops. He alighted at Poniatowski's tent; and, being informed of particulars, instantly flew in a rage to the vizier, whom he loaded with reproaches, and accused of treachery. Recollect-

ing himself, however, he proposed a method by which the fault might be remedied; but, finding his proposal rejected, he posted back to Bender, after having by the grossest insults showed his contempt of the vizier. This violent behaviour of Charles did not promote his interest. The vizier perceived that his stay in Turkey might prove fatal to himself, and therefore determined to get him out of the country as soon as possible, either by fair means or foul. Succeeding viziers adopted the same plan; and at last the grand seignior himself wrote a letter to the king, in which he desired him to depart by next winter, promising to supply him with a sufficient guard, with money, and every thing else necessary for his journey. Charles gave an evasive answer, and determined to procrastinate his journey, as well to gratify his own stubborn temper as because he discovered a correspondence between Augustus and the khan of Tartary, the object of which he had reason to believe was to betray him to the Saxons. When he was therefore again pressed to fix the day of his departure, he replied that he could not think of going before his debts were paid. Being asked how much was necessary for this purpose, he replied, 1000 purses (of thirty sequins each). 1200 purses were instantly sent to the serasquier at Bender, with orders to deliver them to the king of Sweden, but not before he should have begun his journey. By fair promises, however, Charles persuaded him to part with the money; after which, instead of setting out, he squandered away his treasure in presents and gratifications, and then demanded 1000 purses more before he would set out. The serasquier was astonished at this behaviour. He shed tears; and, turning to the king, told him, that his head would be the forfeit of having obliged him with the money. The grand seignior, on being acquainted with this shameful behaviour of Charles, flew into a rage, and called an extraordinary divan, where he himself spoke, a thing very unusual for the Turkish monarchs. It was unanimously agreed that such a troublesome guest ought to be removed by force should other means fail. Orders were therefore positively sent to Charles to depart; and, in case of refusal, to attack him in his quarters. Nothing could equal his obstinacy on this occasion: in spite of the menaces of his enemies, in spite of the intreaties of his friends, he persisted in his resolution; and at last determined to resist, with 300 Swedes, being all the attendants he had, an army of 20,000 janisaries well armed and furnished with cannon. At length he was attacked in earnest; though, even in this extremity, the Turks showed their regard to him, and were tender of his life. Most of the Swedes surrendered, as thinking it the only method of saving the king's life. But Charles became the more obstinate the more desperate his affairs seemed to be. With forty menial servants only, and the generals Hord and Dardorff, he determined to defend himself to the last extremity, and, after the house was on fire, he was forcing his way to an adjoining building, which had a stone roof, when his foot slipped, and his fall saved his life by making him a prisoner. This happened on the 12th of February,

1713. He was now kept prisoner, with all his retinue: and in this situation he was visited in disguise by the unfortunate Stanislaus, whom he desired 'never to make peace with Augustus;' adding, 'we shall soon have a change in our affairs.'

Sweden, from the return of Charles XII. unto his death.—Such were the considerations that still occurred to the mind of Charles; however, at last he seemed inclined to submit to his fate, and began seriously to think of returning to his kingdom, now reduced to the most deplorable situation. His habitation was now fixed at Demotica, a small town about six leagues from Adrianople. Here he was allowed provisions for his own table and those of his retinue; but only twenty-five crowns a day in money, instead of 500 which he had received at Bender. During his residence here he received a deputation from Hesse-Cassel, soliciting his consent to the marriage of Frederick the landgrave with Ulrica Eleonora, princess royal of Sweden; to which he readily agreed. A deputation was also sent him by the regency of Sweden, requesting that he would prepare for returning to his own dominions which were ready to sink under a ruinous war in his absence. What determined him, however, more than any thing to hasten his return, was the following accident:—The new grand vizier Ibrahim Molla, having for private reasons determined to come to a rupture with the czar, invited Charles to a conference, in the style and with the familiarity of an equal. Charles was so much chagrined at this indignity, that he sent his chancellor Mullern to meet the vizier with a pretence that he was sick. To avoid giving offence to this minister, Charles was obliged to keep his bed during his residence at Demotica, which was for ten months after. At last this vizier being strangled, and the Swedish interest at the Porte thereby entirely ruined, he determined to quit Turkey at all events. His departure was to be negotiated by his favorite Grothausen, whom he vested with the character of ambassador extraordinary; sending him to Adrianople with a train of fourteen persons richly dressed. To equip this retinue the king was reduced to the most mortifying shifts, and to the necessity of borrowing money from usurers at fifty per cent. The great object was, to obtain from the vizier money and a passport. Grothausen was received with all the respect due to his rank; but the vizier started difficulties. With regard to the passport, he said, it could be of no use until the consent of the court of Vienna was first obtained; and, as to money, he said, 'his master knew how to give when he thought proper, but it was beneath his dignity to lend; that the king should have every necessary provided for his journey, and possibly the Porte might make some pecuniary present, but he would not have it expected.' The imperial minister, however, removed every difficulty with regard to the passport, by granting it in the most full and ample manner, in the name of the emperor, the princes and states, of Germany. He sent also a present to the king, consisting of a tent of scarlet richly embroidered with gold; a sabre, the handle of which was studded with

jewels; and eight fine horses richly caparisoned. Money, the article most wanted, was entirely forgotten; however, the day was fixed for Charles's departure, and the vizier appointed sixty carriages loaded with all kinds of provisions, and several companies of janisaries and other troops to attend him to the frontiers of Transylvania. On the 14th of October, 1714, Charles quitted his bed at Demotica, and set out for Sweden. All the princes through whose territories he was to pass had given orders for his entertainment in the most magnificent manner; but the king, perceiving that these compliments only rendered his imprisonment and other misfortunes more conspicuous, suddenly dismissed his Turkish attendants, and, assembling his own people, bid them take no care about him, but make the best of their way to Stralsund. After this he set out post, in the habit of a German officer, attended only by colonel Doring. Keeping the bye-roads through Hungary, Moravia, Austria, Bavaria, Wirtemberg, the Palatinate, Westphalia, and Mecklenburg, he arrived on the 21st of November at midnight before the gates of Stralsund. Being unknown, he was admitted with difficulty; but, being soon recognised by the governor, the greatest tokens of joy were shown all over the town. In the midst of the tumult Charles went to bed. He had been booted for sixteen days, and now his legs were swelled to such a degree that it was necessary to cut his boots off. Having slept for some hours, he arose, reviewed his troops, and gave orders for renewing the war with redoubled vigor.

Sweden was now in the greatest distress. On the defeat at Pultowa, the Danes had invaded Schonen, but were defeated by general Steenboek. This victory, however, did not put an end to the war, for the kings of Denmark and Poland, with the czar of Muscovy, entered into stricter bonds of amity than ever. They dreaded the return of Charles to his own dominions, and apprehended that numberless victories would soon efface the remembrance of Pultowa. They determined therefore to make the best use of their time; and Charles never took a more imprudent resolution than obstinately to remain so long in the Turkish dominions. The kings of Denmark and Poland invaded Pomerania; but after laying siege in vain to Stralsund, Wismar, and other places, they were obliged to retire with disgrace. In 1712 the king of Denmark invaded and reduced Bremen and Verden; but the same year met with a terrible defeat from Steenboek, with the loss of a vast number killed and wounded, and almost all their artillery taken. The following year, however, this general being pursued, and surrounded by the united forces of the Russians, Danes, and Saxons, was obliged to throw himself into the neutral town of Tonningen; where he was besieged, and obliged to surrender at discretion, with his whole army. The consequence was an invasion of Finland by the czar; which he totally reduced, after defeating the Swedes in several battles. Indeed the Swedish forces were now unable to cope with almost any enemy. The return of Charles, however, seemed to give new life to the nation.

Though the number of inhabitants was visibly diminished, the levies he had ordered were completed in a few weeks; but the hands left to cultivate the earth consisted of the infirm, aged, and decrepid; so that a famine was threatened in consequence of the military rage which had seized all the youth of the kingdom. The presence of Charles did not now produce those consequences which the allies had feared. The kingdom was too much reduced to be able to furnish the necessary supplies of men and money; and, though the king's courage and military skill were not in the least diminished, the efforts he made, instead of restoring Sweden to its splendor, served entirely to ruin it. In 1715 Prussia declared against him, on account of his demanding back the town of Stettin, which that monarch had seized. To complete his embarrassment, George I. of Britain also became his enemy. The forces of Denmark, Prussia, Saxony, and Hanover, joined to invest Wismar, while a body of 36,000 men formed the siege of Stralsund; at the same time that the czar, with a fleet of twenty large ships of war, and 150 transports, carrying 30,000 men, threw every part of the Swedish coast into the greatest consternation. The heroism of Charles could not prevail against so many enemies; yet he was still so dreadful that the prince of Anhalt, with 12,000 brave troops, did not think himself a match for this furious enemy, when at the head of only 2000, till he had entrenched his army behind a ditch, defended by chevaux de frize. This precaution was not unnecessary; for in the night Charles with his men clambered up the ditch, and attacked the enemy furiously. Numbers, however, at last prevailed, and Charles was obliged to retire, after having seen his favorite Grothusen, general Dardorff, and During, the companions of his exile, killed by his side, he himself being wounded in the breast. This rash attempt was made to save Rugen, whence the town of Stralsund was supplied with provisions. The place was well fortified and garrisoned with 9000 men, with Charles himself at their head; but nothing could resist the efforts of the enemy. The houses were laid in ashes by the bombs; the walls miserably shattered, and large breaches made in them by the cannon; so that by the 17th of December it was proposed to give the assault. The attack on the horn work was desperate; the enemy was twice repulsed; but at last, by dint of numbers, effected a lodgment. The next day Charles headed a sally, in which he dealt terrible destruction among the besiegers, but was at length overpowered and obliged to retreat into the town. At last his officers, apprehending that he must either fall into the hands of the enemy, or be buried in the ruins of the place, intreated him to retire. A retreat, however, was now almost as dangerous as to remain in the town, on account of the fleets of the enemy with which the sea was covered; and this very circumstance induced the king to consent to it. Setting out, therefore, in a small boat with sails and oars, he passed all the enemy's ships and batteries, and arrived safe at Ystedt in Schonen.

To revenge himself for these losses, Charles

invaded Norway with an army of 25,000 men. The Danes were every where defeated and pursued with that vigor for which Charles was so remarkable; but strong reinforcements arriving from Denmark, and provisions failing, he was at last obliged to retire. Soon after this the Swedes lost Wismar; but, when every thing seemed to go to wreck, baron Goertz, the chief minister and favorite of Charles, set on foot a treaty with the czar, by which the most formidable of all Charles's enemies was taken off. The minister prevailed upon the inflexible temper of Charles, by representing to him that the cession of certain provinces to Peter would induce him to assist him in his projects of again dethroning Augustus, and of replacing James on the throne of Britain; which last scheme he had projected out of revenge for the elector of Hanover having seized on the duchies of Bremen and Verden. In consequence of the conferences between the czar and Goertz, the former engaged to send into Poland an army of 80,000 men to dethrone that prince whom he had so long defended. He engaged also to furnish ships for transporting 30,000 Swedes to Germany, and 10,000 into Denmark. This treaty, however, was not fully ratified; and the king's death put a final stop to all the great prospects of Sweden. Charles had resolved on the conquest of Norway, and he marched his army into that cold and barren country in October, when the ground was covered with frost and snow. With 18,000 men he formed the siege of Frederickshall, though the severity of the frost rendered it almost impossible to break the ground. Charles, however, resolved to form trenches: and his soldiers cheerfully obeyed, digging into the ground with the same labor as if they had been piercing a rock. On the 11th of December 1718 the king visited the trenches in the midst of a terrible fire from the enemy, to animate his men by his presence. He took his post in a most dangerous station, standing upon a gabion and leaning over the parapet, while the enemy were firing chain shot at the very spot where he stood. He was intreated to change his station; but he remained obstinate, as if he had been proof against cannon bullets. At last he was seen to fall on the parapet with a deep groan. A small cannon ball had struck him on the temple, beat in the left eye, and forced the right eye quite out of its socket; his right hand in the mean time grasped the hilt of his sword, as if he had meant to revenge the blow. See CHARLES XII.

From the death of Charles XII. until the revolution in 1772.—Charles XII. was succeeded by his sister, princess Ulrica Eleonora, wife to Frederick, hereditary prince of Hesse. On this occasion the states took care to make a previous stipulation for the recovery of their liberties, and obliged the princess to sign a paper to this purpose before entering on the government. Their first care was to make a peace with Great Britain, which the late king intended to have invaded. The Swedes then, to prevent their farther losses by the progress of the Russian, the Danish, the Saxon, and other arms, made many great sacrifices to obtain peace from those powers. In 1720 queen Ulrica Eleonora resigned the

crown in favor of her husband Frederick, who was elected by the States, and crowned May 3d, 1721. The French, about 1738, formed a dangerous party in the kingdom, under the name of the Hats; which not only broke the internal quiet of the kingdom, but led it into a ruinous war with Russia, by which the province of Finland was lost. Their Swedish majesties having no children, it was necessary to settle the succession; especially as the duke of Holstein was descended from the queen's eldest sister, and was, at the same time, the presumptive heir to the empire of Russia. Four competitors appeared: the duke of Holstein Gottorp, prince Frederick of Hesse-Cassel, nephew to the king, the prince of Denmark, and the duke of Deux-Ponts. The duke of Holstein had undoubtedly the best right. His name was Peter Ulric, the son of Charles Frederick, prince of Holstein-Gottorp, and grandson of duke Frederick IV. by Hedwiga Sophia, eldest sister to Charles XII., but he had embraced the Greek religion, that he might succeed to the throne of Russia; which he did, on the death of Elizabeth, and became the unfortunate Peter III. The czarina interposed, and offered to restore all the conquests she had made from Sweden, excepting a small district in Finland, if the Swedes would receive the duke of Holstein's uncle, Adolphus Frederick, bishop of Lubec, as their hereditary prince and successor to their crown. This was agreed to; and a peace was concluded at Abo, under the mediation of his Britannic majesty. This peace was so firmly adhered to by the czarina, that the king of Denmark dropt all resentment for the indignity done his son. Queen Ulrica Eleonora died in 1741, and king Frederick, her husband, in 1751.

King Adolphus Frederick was elected successor to the throne July 4th, 1743; and on July 17th, 1744, had married princess Louisa Ulrica, third sister to the king of Prussia. In 1751 he entered into the possession of his new dignity, which proved to him a crown of thorns. Through a strange medley of affairs and views of interest, the French had acquired vast influence in all the deliberations of the Swedish senate. The intrigues of the senators forced Adolphus to take part in the late war against Prussia; but as that war was disagreeable not only to the people, but also to the king of Sweden, the nation never made so mean an appearance; and, upon Russia's making peace with the king of Prussia, the Swedes likewise made their peace, upon the terms of leaving things as they stood at the beginning of the war. Adolphus died dispirited in 1771, after a turbulent reign of twenty years; and was succeeded by his son Gustavus III.

The most remarkable transaction of the reign of Gustavus III. is the revolution which took place in the government in 1772, by which the king, from being the most limited, became one of the most despotic monarchs in Europe. Ever since the death of Charles XII. the whole power of the kingdom had been lodged in the states; and this power they had on all occasions most grievously abused. Gustavus therefore determined either to seize on that power of which they made such a bad use, or perish in the at-

tempt. By the power of his eloquence, he obtained the acquiescence of all the military in one day: and on the following morning the terrified senate subscribed with acclamations to fifty-seven new articles of government which he presented to them, lodging their power in his own hand. The power, however, thus obtained, the king employed for the good of his subjects. He took care that the law should be administered with impartiality to the richest noble and the poorest peasant, making a severe example of such judges as were proved to have made justice venal. He gave particular attention and encouragement to commerce, was a liberal and enlightened patron of learning and science, and labored strenuously to introduce into his kingdom the most valuable improvements in agriculture that had been made in foreign countries.

Sweden, history of, until the present time.—Gustavus, while thus active in promoting the arts of peace, was not inattentive to those of war. The fleet and the army he placed on a more respectable footing than they had ever before attained. Of this the war with Russia afforded numerous proofs. It is needless for us to enter into a detail of the particulars of that war, which, as well as the astonishing activity and military skill displayed by the Swedish monarch, are fresh in the memory of all our readers. Suffice it to say, that neither Gustavus Adolphus nor Charles XII. gave greater proofs of undaunted courage and military conduct in their long and bloody wars, than were given by Gustavus III. from the end of 1787 to 1790, when peace was restored between the courts of St. Petersburg and Stockholm. In 1792 he entered into the alliance that was formed against the revolutionary government of France; and to raise an army to co-operate with the emperor and the king of Prussia, he was obliged to negotiate large loans, and to impose upon his subjects heavy taxes. The nobles took advantage of that circumstance to prejudice the minds of the people against the sovereign, who had labored so long for their real good. On the 16th of March, 1792, he received an anonymous letter, warning him of his immediate danger from a plot that was laid to take away his life, requesting him to remain at home, and avoid balls for a year. Gustavus, like Cæsar, read the note with contempt, and at a late hour went to a ball that very night. He mingled, without apprehension, among the crowd; and just as he was preparing to retire, in company with the Prussian ambassador, he was surrounded by several persons in masks, one of whom fired a pistol at the back of the king, and lodged the contents in his body. The king languished from the 17th to the 29th of March, when he died with that unshaken courage he had manifested during his life. A few hours before his decease he appointed his brother, the duke of Sudermania, sole regent, till his son, who was then about fourteen, should have attained the age of eighteen. His last words were a declaration of pardon to the conspirators against his life. But his orders in this instance were disobeyed. The assassin Ankarstrom, who had been detected by the pistols and cutlass he dropped, was severely whipped three successive days; on the

last of which his right hand and head were cut off, and his body impaled. Four of his accomplices were beheaded, and others were imprisoned, and some pardoned. Immediately on the death of the king, his son was proclaimed king by the title of Gustavus IV.

Gustavus IV., during his short and unfortunate reign, certainly displayed much of the genius of his illustrious ancestors; but madness was mixed with his genius, and the utmost extravagance of mind with the greatest generosity of intention. His conduct in the unfortunate war which first removed Prussia from the list of European powers, and the singular and unexpected revolution by which his aged uncle, the worthless tool of France, deprived him of his crown, are the most remarkable circumstances of his reign. The unfortunate monarch, with all the fine qualities with which he was adorned, seems to have had in his own country neither friend nor party. He lived for a little while in England, which he quitted suddenly. He then retired to Switzerland, and took the simple name of Gottorp; acquiescing, it would appear, in his own exclusion, and in that of his family. He after this repudiated his wife, became a Moravian in religion, and proposed to marry a

young lady of that sect; all evident signs of mental derangement, belying, in a very melancholy manner, the promise of his early years. The election of Bernadotte to be crown prince of Sweden followed; and the war with Russia (2d September 1812). A treaty of peace had been signed between Great Britain, Russia, and Sweden; and lord viscount Cathcart went out as British ambassador to Russia, and Mr. Thornton to Sweden. An expedition was then prepared, in concert with Great Britain and Russia, under the crown prince (Bernadotte), in Sweden, with the view of attacking Buonaparte in his rear.

It seems that the election of Bernadotte as crown prince or successor to the throne was without any intrigues on his own part, but certainly, without any on the part of the French emperor (who was jealous of this success of his protégée), chiefly on account of the reputation he had acquired through the north of Europe, by his wise and humane conduct in the government of Hanover. On the demise of Charles XIV., after his co-operation with the allies in the deliverance of Europe, Bernadotte mounted the throne, and succeeded in uniting Sweden and Norway under his government, and in establishing in his family the succession to the crown

SWEDENBORG (Emanuel). was born at Stockholm, in Sweden, January 29th, 1688. His father, Jesper Swedberg, was bishop of Skara, in West Gothland, a member of the society for the propagation of the gospel, formed on the plan of that in England, and president of the Swedish churches in England and America. The subject of this memoir, Emanuel, was ennobled by queen Ulrica Eleonora in 1719 and named Swedenborg. His youth was remarkable for uncommon assiduity and application in the usual exercises of that age. A son of the bishop of Skara could not fail to have a good and careful education, suitable to the manner of the times in which he lived. He was placed in the road to useful and extensive knowledge; and he advanced with a speed and success rarely witnessed. In 1709, when little more than twenty years of age, he published at Upsal a small collection of maxims, from Seneca and others, with the following title: *L. Annæi Senecæ et Pub. Syri Mimi, forsan et aliorum, Selectæ Sententiæ, &c.*, which was applauded as a remarkable production for a young man. In 1710 he published at Skara a superior collection of pieces on different subjects, in Latin verse, under the title of *Ludus Heliconius, sive Carmina Miscellanea, quæ variis in locis cecinit Emanuel Swedberg*. The same year he began his travels, first into England, afterwards into Holland, France, and Germany. On his return, in 1714, from his first voyage, he applied himself chiefly to mathematics and physics, in which he soon became so distinguished a proficient that he was made the associate of the celebrated Polhammar, in the superintendance of the construction of public works; and two years afterwards was appointed assessor extraordinary to the Royal College of Mines by Charles XII., who

honored him with frequent conversations, and bestowed upon him a large share of his favor. In 1716, at the age of twenty-eight years, he published essays and observations on the mathematical and physical sciences, under the title of *Dædalus Hyperboreus*. In 1718 he executed a work of the greatest importance at the time of the siege of Fredericks-hall, where he gave evident proof of his extraordinary abilities. Charles could not send his heavy artillery to Fredericks-hall, on account of the badness of the roads, which were then deeply covered with snow. In this extremity Swedenborg brought the sciences to the aid of valor. By help of proper instruments he cut through the mountains, raised the valleys which separated Sweden from Norway, and then sent to his master two galleys, five large boats, and a sloop, loaded with pieces of artillery, to be employed in the siege. The length of this canal was about two miles and a half, Swedish measure, or upwards of sixteen miles English. Mechanism, however, was not his only study; for he gave the Continuation of his *Dædalus Hyperboreus* in 1717 and 1718; and in the latter year an introduction to algebra, under the title of *The Art of the Rules*. He is said to have been the first person in Sweden who wrote on the subject of the integral and differential calculus.

Having lost his patron Charles XII. at the siege of Fredericks-hall, he was taken under the protection of queen Ulrica Eleonora, the sister and successor of that hero; and, in 1719, he was ennobled by her and named Swedenborg, as before observed; from which time he took his seat with the nobles of the equestrian order in the Triennial assemblies of the states. But his elevation to this rank did not lessen his ardor for the sciences;

for he published in the same year A Method to fix the Value of Money, and to determine the Swedish Measures in such a Way as to suppress all the Fractions, and to facilitate the Calculations. About the same time he gave the public a treatise On the Position and Motion of the Earth and the other Planets; with another On the Height of the Tides and the Flux and Reflux of the Sea; which, from information gathered in different parts of Sweden, appeared to have been greater formerly than when he wrote. From some experiments, of which he published an account, he concluded, agreeably to a well-established fact, that the earth is flatter at the poles than at the equator. The three last-mentioned works are said to have been printed in the Swedish language.

Assiduous in his attention to the duties of his office, as assessor of the mines, Swedenborg undertook a second journey into foreign countries, to examine their mines and smelting-works, particularly those of Saxony and Harts. He was particularly noticed at this time by the duke of Brunswick, who did much to facilitate his labors. During these travels, which were undertaken for the improvement of the manufactures of his native country, he printed the following tracts, viz.

1. *Prodromus Principiorum Naturalium, sive Novorum Tentaminum, Chemiam et Physicam, experimentalem geometricè explicandi.*
2. *Nova Observata et Inventa circa Ferrum et Ignam præcipua Naturam Ignis Elementorum, una cum nova Camini inventione.*
3. *Methodus nova inveniendi Longitudines locorum, terra marique, ope Lunæ.*
4. *Modus construendi Receptacula Navalia, vulgo en Suedois, Dockbygnadder.*
5. *Nova constructio Aggeris Aquatici.*
6. *Modus explorandi Virtutes Navigiorum.*
7. *Miscellanea Observata circa res Naturales, præsertim Mineralia, Ignem, et Montium Strata.*

The first six of these tracts were printed at Amsterdam in 1721, and the last at Leipsic and Hamburg in 1722. Few literary men have ever performed so much in so short a time. After his return home in 1722 Swedenborg did not remain idle, but so equally divided his time between the duties of his office, as metallic assessor to the Royal College, and his private studies, that in 1733 he finished his grand work, entitled *Opera Philosophica et Mineralia*, and had it printed under his own direction in 1734, part at Dresden and part at Leipsic; in which year he also went to inspect the mines of Austria and Hungary. This work is divided into three volumes folio: the title of the first is *Principia Rerum Naturalium, sive Novorum Tentaminum, Phænomena Mundi Elementaris philosophicè explicandi*; the second *Regnum Subterraneum sive Minerale de Ferro*; and the third *Regnum Subterraneum sive Minerale de Cupro et Orichalco*; all of them written with great strength of judgment, and ornamented with 155 copper plates, to facilitate the comprehension of the text. The first volume treats of elementary principles; of magnetism, and the variations of the magnetic needle; of the sun and its vortex, the origin of the planetary bodies, and of paradise and the first man. It is remarkable that, in treating on the origin of the planets in our solar system, he

makes express mention of seven primary ones besides the moon and the other satellites. This was more than forty years before the discovery of the seventh planet by Dr. Herschel. The second and third volumes treat on mineralogy, and are generally termed Swedenborg's *Regnum Minerale*. The professor of natural philosophy in the university of Pennsylvania, R. M. Patterson, observes on this work, that 'it is an extraordinary production of one of the most extraordinary men, certainly, that ever lived. Many of the experiments and observations on magnetism, presented in this work, are believed to be of much more modern date, and are unjustly ascribed to much more recent writers.' Indeed it has been frequently remarked, by other learned men, that several important discoveries in science, claimed by different writers, were anticipated, and in some cases minutely described, by Swedenborg.

His name had now been most deservedly enrolled among the academicians at Upsal, Stockholm, and Petersburg; and several distinguished foreigners were anxious to have the honor and advantage of corresponding with him. Wolfius, with many other learned men, valued his correspondence and consulted him on the most difficult subjects. The editors of the *Acta Eruditorum*, at Leipsic, found in his works a rich harvest to ornament their collection with. The authors, also, of the magnificent *Description of Arts and Trades*, which are carried on at Paris, found the second part of Swedenborg's work on iron and the preparation of steel, which abounds with valuable information, of so much consequence, that they translated and inserted the whole in their collection of the best things written on these subjects.

After the year 1737 he made eight different voyages into foreign parts, particularly England and Holland. He visited France and Italy; spent some time at Venice and Rome; and on his return published an account of his travels. Besides the works already mentioned Swedenborg was the author of the following. 1. *Prodromus Philosophiæ ratiocinantis de Infinito, de Causa Creationis, et de Mechanismo Operationis, Animæ et Corporis*; printed at Dresden in 1733. 2. *Economia Regni Animalis*; in two parts, the first printed at Amsterdam in 1740, and the second in 1741. 3. *Regnum Animale*: in three parts; the first two printed at the Hague in 1744; and the third in London in 1746. 4. *De Cultu et Amore Dei*; London, 1745.

In the two works entitled *Economia Regni Animalis* and *Regnum Animale*, the author made many important discoveries in anatomy, and in the circulation of the blood: but, owing to the little pains taken to circulate his philosophical and scientific writings, those discoveries are not generally known to belong to him. The treatise *De Cultu et Amore Dei* is also an extraordinary work. It is in two parts, the first of which traces the origin of the earth from the sun; then treats of paradise; and of the birth, infancy, and love of the first man, or Adam. The second part treats of the marriage of the first man; of the soul; of the intellectual spirit; of the state of integrity, and of the image of God. The existence of a seventh primary planet in our solar

system is again noticed in this little work, which was published about thirty-five years before the discovery made by Dr. Herschel.

Having thus given an account of the principal works, which Swedenborg published before he undertook to write on theology, it will now be proper to state that about this time, 1743 or 1744, an extraordinary change seems to have taken place in his studies and pursuits. His views were directed to subjects which he conceived to be of infinitely greater importance than those of mere literature and science. By many persons the reputation which baron Swedenborg acquired as a philosopher, and the high consideration in which he was held by the public academies of Europe, and by learned men of all nations, would have been prized almost beyond measure: but by him they were not so regarded, when he came to enter upon that new scene which he now states to have opened before him. 'Whatever of worldly honor and advantage,' says he, 'may appear to be in the things before-mentioned, I hold them but as matters of low estimation, when compared to the honor of that holy office to which the Lord himself hath called me, who was graciously pleased to manifest himself to me, his unworthy servant, in a personal appearance, in the year 1743; to open in me a sight of the spiritual world, and to enable me to converse with spirits and angels; and this privilege has continued with me to this day. From that time I began to print and publish various unknown Arcana, that have been either seen by me or revealed to me, concerning Heaven and Hell, the state of man after death, the true worship of God, the spiritual sense of the Scriptures, and many other important truths tending to salvation and true wisdom. And that mankind might receive benefit from these communications, was the only motive which has induced me at different times to leave my home to visit other countries. As to this world's wealth I have what is sufficient; and more I neither seek nor wish for.'

The extraordinary event, or impression of his mind, here related, was followed by a series of theological publications, which have no parallel in the annals of Christianity. We give the titles of them in the order in which they appeared; and as they have obtained in the world no small notice, even among persons of sound judgment and most amiable dispositions, we shall allow them to stand on their own merits, and leave the reader to form his own opinion of the nature of their contents. 1. *Arcana Cælestia*, or Heavenly Mysteries, contained in the sacred Scriptures, or word of the Lord: being an explanation of the spiritual sense of the books of Genesis and Exodus; interspersed with relations of wonderful things seen in the world of spirits, and the heaven of angels. In 8 vols. 4to. London, 1749 to 1756. 2. *De Cælo et Inferno, ex Auditibus et Visis*; a treatise concerning heaven and hell, and the wonderful things heard and seen there, London, 1758. 3. *De Nova Hierosolyma, et Ejus Doctrina Cælesti*; concerning the New Jerusalem, and its heavenly doctrines; London, 1758. 4. *De Ultimo Judicio, et Babylonia Destruata*; concerning the last judgment, and the destruction of Babylon; London, 1758. 5. *De*

Equo Albo, de quo in Apocalypsi; concerning the white horse mentioned in the Revelation; London, 1758. 6. *De Telluribus in Mundo nostro Solari, quæ vocantur Planetæ; et de Telluribus in Cælo Astrifero; deque illarum Incolis, &c.*; concerning the earths in our solar system, and in the starry heaven; with an account of their inhabitants, &c.; London, 1758. 7. *Doctrina Novæ Hierosolymæ de Domino*; the doctrine of the New Jerusalem, concerning the Lord; Amsterdam, 1763. 8. *Doctrina Novæ Hierosolymæ de Scriptura Sacra seu Verbo Domini*; the doctrine of the New Jerusalem concerning the sacred scripture or word of the Lord; Amsterdam, 1763. 9. *Doctrina Vitæ pro Nova Hierosolymæ, ex Præceptis Decalogi*; the doctrine of life for the New Jerusalem, from the precepts of the decalogue; Amsterdam, 1763. 10. *Doctrina Novæ Hierosolymæ de Fide*; the doctrine of the New Jerusalem concerning faith; Amsterdam, 1763. 11. *Continuatis de Ultimo Judicio, et de Mundo Spirituali*; continuation concerning the last judgment, and concerning the spiritual world; Amsterdam, 1763. 12. *Sapientia Angelica de Divina Amore et Divina Sapientia*; angelic wisdom concerning divine love and divine wisdom; Amsterdam, 1763. 13. *Sapientia Angelica de Divina Providentia*; angelic wisdom concerning divine providence; Amsterdam, 1764. 14. *Apocalypsis Revelata*; the apocalypse revealed; Amsterdam, 1766. 15. *Delitiæ Sapientiæ de Amore Conjugiali, &c.*; the delights of wisdom concerning conjugal love; after which follow the pleasures of insanity concerning scortatory love; Amsterdam, 1768. 16. *Sumonaria Expositio Doctrinæ Novæ Ecclesiæ*; a brief exposition of the doctrine of the new church; Amsterdam, 1769. 17. *De Commercio Animæ et Corporis*; concerning the intercourse between the soul and body; Amsterdam, 1769. 18. *Vera-Christiana Religio, continens Universalem Theologian Novæ Ecclesiæ*; Amsterdam, 1771.

These works have all been translated into English, and circulated very extensively both in Great Britain and America. The author left behind him many other works in MS., of which the following have been printed:—1. *Coronis seu Appendix ad Veram Christianam Religionem*; a coronis or appendix to the true Christian religion; London, 1780. 2. *Clavis Hieroglyphica Arcanorum Naturalium et Spiritualium, &c.*; an hieroglyphic key to natural and spiritual mysteries, by way of representations and correspondences; London, 1784. 3. *Summaria Expositio Sensus Interni Librorum Prophetico-Verbi Veteris Testamenti, necron et Psalmorum Davidis*; a summary exposition of the internal sense of the prophetic books of the Old Testament, and of the Psalms of David; London, 1784. 4. *Apocalypsis Explicata secundum Sensus Spirituales*; the apocalypse explained according to the spiritual sense; 4. vols. 4to., London, 1785 to 1789.

Sublime things are announced by all these titles; and though the works are many, and embrace a great variety of subjects, they all assume to be connected by one chain of argument and illustration. The application requisite to pro-

duce so many and such important works, not allowing him to continue the necessary functions of his office as assessor, beyond the year 1747, he resigned his situation in the Royal College, and obtained in the same year permission from the king to retire, and to retain his salary as an appointment for life, without any prejudice to his title and rank. He assisted as a member of the house of nobles during several diets; and his behaviour was such as to procure him universal esteem and respect. He was honored with the favor and particular kindness of the kings who reigned during his time; and all who had the happiness of enjoying his company soon became sensible of his superior wisdom, erudition, and virtue. The rules of life which he laid down for his own practice, and which after his death were found placed and repeated in various parts of his MSS., bespeak a temper of mind truly Christian, and are well worthy of being universally observed. These were, 1. 'To read often, and to meditate well on, the word of the Lord. 2. To be always resigned and content under the dispensations of Providence. 3. Always to observe a propriety of behaviour, and to preserve the conscience clear and void of offence. 4. To obey that which is ordained; to be faithful in the discharge of the duties of our employment; and to do every thing in our power to render ourselves as universally useful as possible.'

Of the particular circumstances connected with the appointment of this extraordinary man to the office, which he says he was called by the Lord to perform, we have no account that can be depended upon but that which he has himself given in several of his printed works, particularly in his work entitled *True Christian Religion*, in the chapter on the consummation of the age, the coming of the Lord, and the new heaven and new church, n. 779, 780; from which we quote the following passage:—'That this second coming of the Lord is effected by the instrumentality of a man (meaning himself), before whom he hath manifested himself in person, and whom he hath filled with his spirit, to teach from him the doctrines of the new church by means of the word.—Since the Lord cannot manifest himself in person (to the world), as was shown above, and yet he foretold that he would come and establish a new church, which is the New Jerusalem, it follows that he will effect this by the instrumentality of a man, who is able not only to receive the doctrines of that church in his understanding, but also to publish them in print. That the Lord hath manifested himself before me his servant, and sent me on this office, and that afterwards he opened the sight of my spirit and thereby let me into the spiritual world, and granted me to see the heavens and the hells, and also to converse with angels and spirits, and this now continually for several years, I testify in truth; and farther, that from the first day of my call to this office, I never received any thing appertaining to the doctrines of that church from any angel, but from the Lord alone, whilst I was reading the word. To the end that the Lord might be constantly present, he revealed to me the spiritual sense of his word, in which sense divine truth is in its light, and in this light he is

continually present.' A similar statement is made in n. 851 of the same work, where he asserts, 'that the privilege of conversing with angels and spirits had continued with him for twenty-seven years,' that is, from 1743 to 1770, when he wrote that work two years before his death!

The following are, according to one of his respectable followers, the chief articles of doctrine deducible from the whole of baron Swedenborg's *Theological Writings*, viz. 1. That Jehovah God, the creator and preserver of heaven and earth, is a Being of infinite love, wisdom, and power, that he is one in essence and in person, in whom nevertheless is a divine trinity, consisting of Father, Son, and Holy Spirit, like soul, body, and operation in man; and that the Lord and Saviour Jesus Christ is that God. 2. That Jehovah God himself came down from heaven as divine truth, which is the word, and took upon him human nature, for the purpose of subduing and removing the powers of darkness, of restoring the spiritual world to order, of preparing the way for a new church upon earth, and thus of accomplishing the great work of redemption: that through the process of sufferings and temptations he also glorified his humanity by uniting it with his essential divinity; and that all who believe in him from the heart, with the understanding, and in the life, will be saved. 3. That the word of the Lord, or sacred Scripture, was written by divine inspiration; that it contains an internal spiritual sense for the use of angels in heaven, and an external natural sense for the use of men upon earth; and that in each sense it is holy and divine. That these two senses, the spiritual and the natural, are united by correspondences, like soul and body; and thus that the word is the medium of communication with heaven, and of conjunction with the Lord. 4. That all evils, whether of affection, of thought, or of life, ought to be shunned as sins against God, because they proceed from the devil, that is, from hell, and destroy in man the capacity of enjoying the happiness of heaven. But that, on the other hand, good affections, good thoughts, and good actions, ought to be cherished and performed, because they are of God, and from God; and that every act of love and charity, of justice and equity, both towards society in general and towards individuals in particular, ought to be done by man as of himself, nevertheless under the acknowledgment and belief that they are really and truly from the Lord, operating in him and by him. 5. That man, during his abode in the world, is kept in a state of spiritual equilibrium between heaven and hell, or good and evil, in consequence of which he enjoys free-will in spiritual as well as natural things, and has the capacity either of turning himself to the Lord, or of separating himself from the Lord; that so far as he does the work of repentance, and lives in charity according to the truths of faith, so far his sins are remitted, that is to say, so far his evils are removed; and in the same proportion also he is regenerated, or created anew by the Lord. 6. That man is not life in himself, but only a recipient of life from the Lord, who alone is life in himself; which life is communicated by influx to all in the spiritual world, whether

belonging to heaven or to hell, and to all in the natural world; but is received differently by each according to the quality of the recipient subject. 7. That adequate means of salvation are, by the divine mercy and providence of the Lord, extended to all of the human race without exception; and consequently that men of every persuasion or denomination upon the face of the earth, whether they be Christians, Jews, Mahometans, or Pagans, may be saved, if they live in mutual love and charity from religious motives, according to the best of their knowledge and understanding. But that nevertheless the new and true Christian religion, inasmuch as it is more immediately derived from our Lord and Saviour Jesus Christ, who is the One only God of heaven and earth, is of all religions the most capable of effecting close and intimate conjunction with him; and on that account is to be esteemed more excellent, more heavenly, and more divine, than any other. 8. That every event or occurrence in human life, whether of prosperity or of adversity, is under the immediate superintendance and direction of the Divine Providence; and that nothing does or can befall man, either in his collective or in his individual capacity, but what even in the most minute, as well as in the more important circumstances attending it, is made to contribute in a way known only to infinite wisdom, to the final benefit and advantage of those who love and obey the Lord. 9. That immediately on the death of the material body, which will never be reassumed, man rises again as to his spiritual or substantial body, wherein he exists in a perfect human form, with every faculty which he before enjoyed; and that his eternal state, as to happiness or misery hereafter, will altogether depend on the quality of his past life, whether it has been good or evil. 10. But that with respect to children dying before they come to the use of reason, and the exercise of their own judgment, all such, whether baptised or unbaptised, whether within the Christian church or without it, and whether they be the offspring of godly or of ungodly parents, are received into heaven by the Lord, and after instruction, or improvement in understanding and wisdom, participate in all the happiness and perfection of angels. 11. That there is not in the universal heaven a single angel that was created such at first, nor a single devil in all hell that had been created an angel of light, and was afterwards cast out of heaven; but that all both in heaven and in hell are of the human race, in heaven such as had lived in the world in heavenly love and faith, and in hell such as had lived altogether according to the principles of self-love and the love of the world. 12. That true conjugal love, which can only exist between one husband and one wife, is a primary characteristic of the new church, being grounded in the marriage or conjunction of good and truth, and corresponding with the marriage of the Lord and his church; and therefore it is more celestial, spiritual, holy, and pure, than any other love in angels or men. 13. That baptism and the holy supper are sacraments of divine institution, and are to be permanently observed; baptism being an external medium of introduction

into the church, and a sign representative of man's purification and regeneration; and the holy supper being an external medium, to those who receive it worthily, of introduction, as to spirit, into heaven, and of conjunction with the Lord, of which it is also a sign and seal. 14. That the last judgment, so frequently spoken of in the gospels, and in the Apocalypse, being a separation of the evil from the good in the spiritual world, where heretofore they had been collected and mixed in society together, from the time of the Lord's first advent into the world till the time of his second advent, was actually accomplished in the year 1757; when the former heaven and the former earth, or the old church, passed away according to the Scriptures, and the foundation of a new church was laid, wherein all things are become new. 15. That therefore, as an act of mercy towards the human race, which would otherwise have perished in eternal death, the second advent of the Lord has already taken place and still continues in the present day; being a coming not in person, but in the power and glory of the spiritual sense of his holy word, as demonstrated in the theological writings of his servant Emanuel Swedenborg: and thus that the holy city, New Jerusalem, is now descending from God out of heaven, prepared as a bride adorned for her husband.

'In addition to these articles of doctrine,' says the gentleman to whom we are indebted for the above summary, 'there are many other important subjects contained in the writings of Swedenborg. The doctrine of correspondences is one, according to which, he says, the whole of the Sacred Scriptures is written, and without a knowledge of which its true and genuine sense cannot possibly be understood. This doctrine he represents as having been 'hidden now for some thousands of years, viz. ever since the time of Job; at which time, and in the ages before it, the science of correspondences was esteemed the chief of all sciences, being the fountain of wisdom to man, because it was the fountain of knowledge concerning spiritual things relating to heaven and the church; but, by reason of its being perverted to idolatrous purposes, it was so obliterated and destroyed, by the divine providence of the Lord, that no traces of it were left remaining: that nevertheless it is at this time again revealed by the Lord, in order to effect a conjunction of the members of the church with him, and their association with the angels, which purposes are effected by the word, in which all and every thing are correspondences.'

He further declares 'that there is a sun in the spiritual world distinct from the sun of the natural world; that the former sun is pure love, and the latter sun pure fire; that therefore whatever proceeds from the spiritual sun, by reason of its being pure love, hath something of life in it, and whatever proceeds from the natural sun, by reason of its being pure fire, hath in it nothing of life; that hence ariseth the distinction between what is spiritual, and what is natural,' the one not being a refinement, attenuation, or exaltation of the other, in the way of continuous degrees, from grosser to purer of the

same order, but a discreetly distinct and superior order of things, just as the light of truth in the mental eye is discreetly distinct from the light of the sun or of a candle in the bodily eye; 'which distinction heretofore unknown (or at least not properly attended to) is now revealed, together with the source of that light which enlighteneth the human understanding with wisdom, and the source of that heat which kindleth love in the human will.'

He also affirms 'that the planets in our solar system are inhabited by human beings, nay, that millions of planetary bodies, revolving about other suns in the starry heavens, are in like manner the abodes of men, and that he himself has actually been permitted to visit many of them, not in body, but in spirit. The manner in which he explains this subject is really curious, and well worthy of notice. He states that, in consequence of his intercourse with angels and spirits for many successive years of his life, he discovered that distances in the spiritual world are not like distances here on earth, but are altogether according to the several states of the interiors of the inhabitants. They who are in a similar state are together in one society, and in one place; for all presence is caused by similitude of state, and all distance by dissimilitude of state. Hence to be present with any spirit or angel, whether he be from this earth, or from any other earth in the universe, it is only requisite to be in a similar state with such spirit or angel as to the interiors of the mind, that is, as to the interior affections and thoughts. And in this way, he says, it is as possible for the spirit of a man still living in the body, whose interiors are open to heaven, to be led by the Lord into a similitude of state with the spirits and angels from other earths or planets, and even with the inhabitants themselves, as with the spirits, angels, and distant inhabitants of this earth. Now when the interior faculties of a man are so far opened as to enable him to see and converse with spirits and angels (which however is a rare case in the present day, owing to causes which need not be here stated), then such spirits and angels as are present with him (and every man is surrounded with beings of this description) can see through his eyes the natural objects of this world and hear through his ears the conversation that passes among men; which they cannot otherwise do. So, again, the man whose interiors are open may, by being brought into a similar state with an inhabitant of some distant earth, in like manner see through the eyes of such inhabitant, if his interiors are open, the natural objects of his world, and hear through his ears the natural sounds there produced.

This doctrine of the possibility of man's seeing and conversing with spirits and angels, Swedenborg confirms by a variety of testimonies from the sacred Scriptures, particularly by the cases of Abraham and Sarah, Lot, the inhabitants of Sodom, Joshua, Gideon, Manoah and his wife, Zacharias, Mary, John, and many others, who all saw and conversed with angels as with men. He adds also his own experience, saying, 'Inasmuch as it hath been granted me by the Lord to be at one and the same time in

the spiritual world and in the natural world, and thereby to converse with angels as with men, and thus to become acquainted with the states of those who, after death, flock together into that heretofore unknown world (for I have conversed with all my relations and friends, and likewise with kings and princes, and men of learning, after their departure out of this life, and this now for twenty-seven years without interruption), therefore I am able to describe the states of men after death, from lively experience, both in relation to such as have lived good lives, and such as have lived evil.' He then goes on to describe the successive states of those after death who had confirmed themselves in false doctrines, by a misapplication and perversion of the sacred Scriptures. See *True Christian Religion*, n. 281.

We select another passage from the same work, n. 792, 794, for the information of the reader, which, with the other peculiarities taught by Swedenborg will furnish a just view of the nature of his publications, and the extraordinary character of the writer. 'With respect to the state and nature of a future life, mankind have heretofore remained in the dark: it has been generally believed that man after death is a mere soul, and the common idea concerning such soul has been that it is something like ether, or air, consequently that it is like the breath which goes out of a man's body when he dies, in which nevertheless there resides some vital principle. But then it has been conceived that this vital principle neither has the faculty of seeing, such as belongs to the eye, nor of hearing, such as belongs to the ear, nor of speaking, such as belongs to the organs of speech: when nevertheless man after death is as much a man as he was before, and so little changed that he does not know but he is still living in the former world; for he sees, hears, and speaks, as in the former world; he walks, runs, and sits, as in the former world; he lies down, sleeps, and wakes, as in the former world; he eats and drinks, as in the former world; he enjoys conjugal delight, as in the former world; in a word, he is a man in all and every respect. From which circumstances it is evident that death is not an extinction but a continuation of life, and consequently that it is only a passage from one state to another.—In consequence of what I have seen, and been an eye-witness of for many years together, I can assert the following facts relating to the spiritual world; that there are earths in that world, just as in the natural world, and that there are also plains and valleys, mountains and hills, fountains and rivers; that there are paradises, gardens, groves, and woods; that there are cities, with palaces and houses contained therein; also that there are writings and books, employments and merchandises; and that there are gold, silver, and precious stones; in a word, that there is in the spiritual world all and every thing that is in the natural world, but that in heaven such things are in an infinitely more perfect state. The difference is, that all things which are seen in the spiritual world are created in a moment by the Lord, as houses, paradises, meats, and other things, and that they

are created according to a correspondence with the interiors of angels and spirits, that is, of their affections and thoughts; whereas all things that are seen in the natural world begin to exist and grow from seed.'

The Rev. Thomas Hartley, formerly rector of Winwick, in Northamptonshire, who was personally acquainted with Swedenborg, describes his character as follows:—'The extensive learning displayed in his writings evinces him to be the scholar and the philosopher; and his polite behaviour and address bespeak the gentleman. He affects no honor, but declines it; pursues no worldly interest, but spends his substance in travelling and printing, in order to communicate instruction and benefit to mankind; and he is so far from the ambition of heading a sect, that, wherever he resides on his travels, he is a mere solitary, and almost inaccessible, though in his own country of a free and open behaviour. He has nothing of the precisian in his manner, nothing of melancholy in his temper, and nothing in the least bordering upon the enthusiast in his conversation or writings; in the latter of which he delivers facts in the plain style of narrative, speaks of his conversation with spirits and angels with the same coolness that he treats of earthly things, as being alike common to him; he proves all points of doctrine from Scripture testimony; always connects charity and a good life with true faith; and is, upon the whole, the most rational divine I ever read.'—Hartley's Preface to the Intercourse between the Soul and Body. He died at his lodgings in Great Bath Street, Cold Bath Fields, Clerkenwell, London, on the 29th of March 1772, in the eighty-fifth year of his age; and, after lying in state at an undertaker's, his remains were deposited in a vault under the Swedish church in Prince's Square, Ratcliff Highway.

SWEDENBORGIANS, or, as they call themselves, the Members of the New Jerusalem Church, are the followers of Emanuel Swedenborg, a Swedish nobleman, distinguished by his writings as a philosopher and theologian; for an account of whom, and the doctrines taught by him, see the preceding article. During the lifetime of this author, and for some years after his death, it appears that only a few individuals in his own country, and still fewer in England, cordially embraced his doctrines. In 1782, however, a society of gentlemen was formed in Manchester, for the purpose of translating, printing, and publishing the author's works in English; and the next year, 1783, a similar society was formed in London. But it was not till the year 1788 that the followers of Swedenborg instituted public worship separately from the other professors of Christianity: in that year they opened a chapel in Great East Cheap, London, as members of the New Jerusalem Church; and their doctrines soon began to excite very general attention. In a few years societies were formed in different parts of Great Britain, and numerous places of worship have either been erected or engaged by them in some of the principal towns, as well as villages, throughout the kingdom. It is supposed there are many thousands in England, Scotland, and Ireland, who profess baron

Swedenborg's doctrines; and it is well known that his writings have obtained a favorable reception among many distinguished and well-informed persons in France, Holland, Germany, Sweden, Denmark, Russia, Poland, North and South America, the West India Islands, the East Indies, and other distant parts of the globe. In England the admirers of his system use a printed liturgy, and have appropriate forms for baptism, the holy supper, and other rites of the church, whereby uniformity of worship is established among them. They also hold annual conferences of the ministers and other members of their church; and, on the whole, they appear to be in a prosperous condition. They have among their writers of eminence, who have distinguished themselves by their successful vindications of the character and writings of Swedenborg against the various attacks that have from time to time been made against them. The Rev. John Clowes, rector of St. John's Church, Manchester, the translator of many of the baron's works, and the able advocate of the New Jerusalem doctrines, completely refuted the calumnies brought against the noble author by the abbé Barruel. Mr. Robert Hindmarsh, also of London, formerly printer extraordinary to his royal highness the prince of Wales, and afterwards George IV., succeeded in answering Dr. Priestley, Mr. Wesley, and some others. And the Rev. Samuel Noble, minister of the New Jerusalem church in Cross Street, Hatton Garden (late the Caledonian Asylum, where Mr. Irving formerly officiated), has been said to be equally successful in silencing the ungenerous and ill-founded attacks which have been more recently directed against the doctrines of the New Jerusalem. Besides these writers, many others might be named, whose varied productions are held in high estimation, and do credit to the cause which they are intended to serve.

SWEEP, *v. a., v. n., & n. s.* } *Part, & part.*
SWEEPINGS, *n. s.* } *pass.*, swept. *Sax.*
SWEEPNET, } *гпан*; and *Swed.*
SWEEPSTAKE, } *svepa*. To drive
SWEEPY, *adj.* } away with a besom;

to clean with a brush or besom: hence to carry off; carry with pomp or parade: pass with violence or pomp: the act or instrument of sweeping; violent destruction; direction of any particular motion; compass: the sweepings are that which is swept away: sweepnet, a net that sweeps all: sweepstake, a man that wins all: sweepy is far-reaching; passing with great speed or violence.

The river Kishon *sweeps* them away. *Jud. v.*
 A poor man that oppresses the poor, is like a *sweeping* rain which leaveth no food.

What woman, having ten pieces of silver, if she lose one, doth not *sweep* the house, and seek diligently till she find it? *Luke, xv. 8.*

The blustering winds striving for victory *sweep* the snow from off the tops of those high mountains, and cast it down into the plains in such abundance that the Turks lay as men buried alive.

Let frantic Talbot triumph for a while,
 And, like a peacock, *sweep* along his tail.

Shakspeare. Henry VI

Though I could,
With barefaced power, *sweep* him from my sight,
And bid my will avouch it; yet I must not.

Shakspeare.

She *sweeps* it through the court with troops of
ladies,

More like an empress than duke Humphrey's wife.

Id.

Is 't writ in your revenge,
That *sweepstake* you will draw both friend and foe,
Winner and loser?

Id.

She was a *sweepnet* for the Spanish ships, which
happily fell into her net.

Camden.

Cowen in her course

Towards the Sabrinian shores, as *sweeping* from her
source,

Takes Tow.

Drayton.

In countries subject to great epidemical *sweeps*,
men may live very long; but, where the proportion
of the chronical distemper is great, it is not likely to
be so.

Graunt.

Flying bullets now

To execute his rage appear too slow;
They miss or *sweep* but common souls away;
For such a loss Opdam his life must pay.

Waller.

My looking is the fire of pestilence,
That *sweeps* at once the people and the prince.

Dryden.

I have already *swept* the stakes, and with the
common good fortune of prosperous gamesters can
be content to sit.

Id.

Before tempestuous winds arise,

Stars shooting through the darkness glide the night
With *sweeping* glories, and long trails of light.

Id.

They rush along, the rattling woods give way,
The branches bend before their *sweepy* sway.

Id.

A door drags, when, by its ill hanging on its
hinges, or by the ill boarding of the room, the bot-
tom edge of the door rides in its *sweep* upon the
floor.

Moxon's Mechanical Exercises.

A torrent swelled

With wintry tempests, that disdains all mounds,
Breaking away impetuous, and involves
Within its *sweep*, trees, houses, men.

Philips.

To *sweep* fame, power, and wealth away;
The past is all by death possest,
And frugal fate that guards the rest,

By giving, bids them live to-day.

Fenton.

Having made one incision a little circularly, being
a second, bringing it with an apposite *sweep* to meet
the other.

Sharp.

Descend, ye nine; descend, and sing;
The breathing instrument silent,

Wake into voice each silent string,
And *sweep* the sounding lyre.

Pope.

A duke holding in a great many hands, drew a
huge heap of gold; but never observed a sharper,
who under his arm *swept* a great deal of it into his
hat.

Swift.

Should this one broomstick enter the scene, covered
with dust, though the *sweepings* of the finest
lady's chamber, we should despise its vanity.

Id.

SWEET, *adj.* & *n. s.*

SWEET'BREAD, *n. s.*

SWEET'BRIAR,

SWEET'EN, *v. a.* & *v. n.*

SWEETEN'ER, *n. s.*

SWEET'HEART,

SWEET'ING,

SWEET'ISH, *adj.*

SWEETLY, *adv.*

SWEET'MEAT, *n. s.*

SWEET'NESS,

Sax. *ƿeete*; Belg.
zoet; Dan. *soed*; Goth.
soet; Lat. *suavis*. Lusci-
ous to the taste or
smell; eye or ear;
soft; mild; gentle;
grateful; something
pleasing to a sense,
or the senses; a word
of endearment; a per-
fume: sweetbread is

the pancreas of a calf: sweet briar, a fragrant
shrub: to sweeten is, to make sweet, mild, or
kind; to palliate; reconcile; soften: and, as a
verb neuter, to grow sweet: sweetener corres-
ponds: sweetheart is a lover or mistress: sweet-
ing, a particularly sweet apple; a term of en-
dearment: sweetish, somewhat sweet: sweetly,
in a sweet manner; delicately: sweetmeat, a
sweet preserve: sweetness, the quality of being
sweet; lusciousness; mildness; agreeableness.

The best wine for my beloved goeth down *sweetly*.

Cant.

The right form, the true figure, the natural colour
that is fit and due to the dignity of a man, to the
beauty of a woman, to the *sweetness* of a young babe.

Ascham.

A child will chuse a *sweeting*, because it is pre-
sently fair and pleasant, and refuse a runnet, be-
cause it is then green, hard, and sour.

Id. Schoolmaster.

She, the *sweetness* of my heart, even *sweetening*
the death which her *sweetness* brought upon me.

Sidney.

Mopsa as glad as of *sweetmeats* to go of such an
errand, quickly returned.

Id.

Balm his foul head with warm distilled waters,
And burn *sweet* wood, to make the lodging *sweet*.

Shakspeare.

Heaven bless thee;

Thou hast the *sweetest* face I ever looked on.

Id.

Let me report to him

Your *sweet* dependency, and you shall find
A conqueror that will pray in aid of kindness.

Id.

Pluck out

The multitudinous tongue, let them not lick
The *sweet* which is their poison.

Id. Coriolanus.

Sweet! leave me here a while;

My spirits grow dull, and fain I would beguile
The tedious day with sleep.

Shakspeare.

Give me an ounce of civet to *sweeten* my imagina-
tion.

Id. King Lear.

Mistress, retire yourself

Into some covert; take your *sweethearts*,
And pluck o'er your brows.

Shakspeare.

Trip no further, pretty *sweeting*;

Journies end in lovers meeting.

Id.

Where a rainbow hangeth over or toucheth, there
breatheth a *sweet* smell; for that this happeneth but
in certain matters which have some *sweetness*, which
the dew of the rainbow draweth forth.

Bacon.

Time changeth fruits from more sour to more
sweet; but contrariwise liquors, even those that are
of the juice of fruit, from more *sweet* to more sour.

Id. Natural History.

For March come violets and peach-tree in blossom,
the cornelian-tree in blossom, and *sweetbriar*.

Bacon.

Where a wasp hath bitten in a grape, or any fruit,
it will *sweeten* hastily.

Id. Natural History.

This honey tasted still is ever *sweet*.
Nothing so *sweet* is as our country's earth,
And joy of those from whom we claim our birth.

Chapman.

What softer sounds are these salute the ear,
From the large circle of the hemisphere,
As if the center of all *sweets* met here? *Ben Jonson.*

Whence frowns my *sweet*?

Have I too long been absent from these lips?

Id.

I would have my love

Angry sometimes, to *sweeten* off the rest
Of her behaviour.

Id. Catiline.

If every *sweet*, and every grace,
Must fly from that forsaken face.

Cureu.

Never tie yourself always to eat meats of easy digesture, as veal, pullets, or *sweetbreads*.

Harvey on Consumption.

One thing, *sweetheart*, I will ask,
Take me for a new-fashioned mask. *Cleveland.*

The dulcimer, all organs of *sweet* stop. *Milton.*

The Pleiades before him danced,
Shedding *sweet* influence. *Id.*

Hail! wedded love,
Perpetual fountain of domestic *sweets*! *Id.*

Shred very small with thyme, *sweet*-margory, and
a little winter savoury. *Walton's Angler.*

Serene and clear harmonious Horace flows,
With *sweetness* not to be express in prose. *Roscommon.*

His *sweetness* of carriage is very particularly re-
membered by his contemporaries. *Fell.*

Mercy has, could Mercy's self be seen,
No *sweeter* look than this propitious queen. *Waller.*

Powder of crabs' eyes and claws, and burnt egg-
shells, are prescribed as *sweeteners* of any sharp
humours. *Temple.*

The sails drop with rain,
Sweet waters mingle with the briny main. *Dryden.*

Euryalus,
Than whom the Trojan host
No fairer face or *sweeter* air could boast. *Dryden's Æneid.*

Now since the Latian and the Trojan brood
Have tasted vengeance, and the *sweets* of blood,
Speak. *Id.*

As, in perfumes,
'Tis hard to say what scent is uppermost;
Nor this part musk or civet can we call,
Or amber, but a rich result of all:
So she was all a *sweet*. *Dryden.*

Sweetbread and collops were with skewers pricked
About the sides; and imbibing what they decked. *Id.*

Corregio has made his memory immortal, by the
strength he has given to his figures, and by *sweeten-*
ing his lights and shadows, and melting them into
each other so happily that they are even impercept-
ible. *Id. Dufremoy.*

She interprets all your dreams for these,
Foretells the estate, when the rich uncle dies,
And sees a *sweetheart* in the sacrifice. *Id. Juvenal.*

There was plenty, but the dishes were ill sorted;
whole pyramids of *sweetmeats* for boys and women,
but little solid meat for men. *Dryden.*

These lessons may be gilt and *sweetened* as we
order pills and potions, so as to take off the disgust
of the remedy. *L'Estrange.*

A wench was wringing her hands and crying; she
had newly parted with her *sweetheart*. *Id.*

If a child cries for any unwholesome fruit, you
purchase his quiet by giving him a less hurtful
sweetmeat: this may preserve his health, but spoils
his mind. *Locke.*

Sweet and stinking commonly serve our turn for
these ideas, which, in effect, is little more than to
call them pleasing or displeasing; though the smell
of a rose and violet, both *sweet*, are certainly very
distinct ideas. *Id.*

All kindnesses descend upon such a temper, as
rivers of fresh water falling into the main sea; the
sea swallows them all, but is not changed or *sweet-*
ened by them. *South.*

Thy mercy *sweetened* every soil,
Made every region please;

The hoary Alpin hills it warmed,
And smoothed the Tyrrhene seas.

Addison's Spectator.

At a lord-mayor's feast, the *sweetmeats* do not
make their appearance till people are cloyed with
beef and mutton. *Addison.*

This old man's talk, though honey flowed
In every word, would now lose all its *sweetness*. *Id.*

Flowers

Innumerable, by the soft south-west
Opened, and gathered by religious hands,
Rebound their *sweets* from the odoriferous pavement.
Prior.

When metals are dissolved in acid menstruums,
and the acids, in conjunction with the metal, act
after a different manner, so that the compound has a
different taste much milder than before, and some-
times a *sweet* one; is it not because the acids adhere
to the metallic particles, and thereby lose much of
their activity? *Newton's Opticks.*

Make your transparent *sweetmeats* truly nice,
With Indian sugar and Arabian spice. *King's Cookery.*

The streets with treble voices ring,
To sell the bounteous product of the spring;
Sweet-smelling flowers, and elders early bud. *Gau.*

They esteemed that blood pituitous naturally,
which abounded with an exceeding quantity of
sweetish chyle. *Floyer.*

The balmy zephyrs, silent since her death,
Lament the ceasing of a *sweeter* breath. *Pope.*

Praise the easy vigour of a line,
Where Denham's strength and Waller's *sweetness*
join. *Id.*

When you roast a breast of veal, remember your
sweetheart the butler loves a *sweetbread*. *Swift.*

Be humbly minded, know your post;
Sweeten your tea, and watch your toast. *Id.*

Those softeners, *sweeteners*, and compounders, shake
their heads so strongly that we can hear their
pockets jingle. *Id.*

No poet ever *sweetly* sung,
Unless he were like Phœbus young;
Nor ever nymph inspired to rhyme,
Unless like Venus in her prime. *Id.*

They are allowed to kiss the child at meeting and
parting; but a professor, who always stands by,
will not suffer them to bring any presents of toys or
sweetmeats. *Id.*

A man of good education, excellent understand-
ing, and exact taste; these qualities are adorned
with great modesty, and a most amiable *sweetness* of
temper. *Id.*

Sweet expresses the pleasant perceptions of almost
every sense: sugar is *sweet*, but it hath not the same
sweetness as musick; nor hath musick the *sweetness*
of a rose, and a *sweet* prospect differs from them all:
nor yet have any of these the same *sweetness* as dis-
course, counsel, or meditation hath; yet the royal
psalmist saith of a man, we took *sweet* counsel to-
gether: and of God, my meditation of him shall be
sweet. *Watts.*

Devotion softens his heart, enlightens his mind,
sweetens his temper, and makes every thing that
comes from him instructive, amiable, and affecting.
Law.

SWEETWILLIAM. See DIANTHUS.

SWEETWILLIAM OF BARBADOES, a species of
ipomoea.

SWEETWILLOW. See MYRICA.

SWELL, *v. n., v. a., &* } *Part. pass.* swollen.
SWELLING, *n. s.* [*n. s.* } Sax. *ƿellan*; Belg.
swellen; Teut. *schwellen*. To grow bigger; grow
turgid; extend; inflate; aggravate; cause to
grow big; extension of bulk: a swelling is an
effort to grow big, or for vent; a morbid tumor;
protuberance.

I will help every one from him that *swelleth* against
him, and will set him at rest. *Ps. xii. 6.*

This iniquity shall be as a breach ready to fall,
swelling out in a high wall. *Isaiah xxx. 13.*

Strangely visited people,
All swollen and ulc'rous, pitiful to the eye,
The mere despair of surgery he cures.

Shakspeare. Macbeth.
My pity hath been balm to heal their wounds,
My mildness hath allayed their swelling griefs.

Shakspeare.
Here he comes, swelling like a turkey-cock. *Id.*
The hearts of princes kiss obedience,
So much they love it; but to stubborn spirits
They swell and grow as terrible as storms. *Id.*

O for a muse of fire, that would ascend
The brightest heaven of invention!
A kingdom for a stage, princes to act,
And monarchs to behold the swelling scene. *Id.*

The swan's down feather,
That stands upon the swell at full of tide,
And neither way inclines. *Id. Antony and Cleopatra.*

All these miseries proceed from the same natural
causes, which have usually attended kingdoms swollen
with long plenty, pride, and excess. *Clarendon.*

Peleus and Telephus, exiled and poor,
Forget their swelling and gigantick words. *Roscommon.*

Propitious Tyber smoothed his wat'ry way,
He rolled his river back, and poised he stood,
A gentle swelling, and a peaceful flood. *Dryden's Æneid.*

Swol'n in his breast; his inward pains increase,
All means are used, and all without success. *Dryden.*

In all things else above our humble fate,
Your equal mind yet swells not into state. *Id.*

The king of men, who, swol'n with pride,
Refused his presents, and his prayers denied. *Id.*
My heart was torn in pieces to see the husband
suppressing and keeping down the swellings of his
grief. *Tatler.*

Your youth admires
The throes and swellings of a Roman soul,
Cato's bold flights, the extravagance of virtue. *Addison.*

The superficies of such plates are not even, but
have many cavities and swellings, which, how shal-
low soever, do a little vary the thickness of the place. *Newton's Opticks.*

There is not a chronical disease that more fre-
quently introduces the distemper I am discoursing of
than strumous or scrophulous swellings or ulcers. *Blackmore.*

It is low ebb with his accuser, when such peccadil-
los are put to swell the charge. *Atterbury.*

SWELT, *v. n.* To break out in sweat.
Chearful blood in faintness chill did melt,
Which, like a fever fit, through all his body swelt. *Spenser's Faerie Queene.*

If the sun's excessive heat
Makes our bodies swelter,
To an osier hedge we get
For a friendly shelter;
There we may
Think and pray,
Before death
Stops our breath. *Chalkhil.*

Some would always have long nights and short
days; others again long days and short nights; one
climate would be scorched and sweltered with ever-
lasting dog-days, while an eternal December blasted
another. *Bentley's Sermons.*

SWELLING. See SURGERY and TUMOR.
SWELLING, WHITE, or Paronychia. See
SURGERY, Index.

SWENO I., or Sveno, SWAN, SWEIN, or

SWEYN, a king of Denmark, who flourished in
the tenth century, twice invaded England, con-
quered part of it, and became father of Canute
the Great, who conquered the whole of it, and
reigned many years. See DENMARK and ENG-
LAND.

SWENO, II. and III. See DENMARK.
SWENO'S STONE, an ancient monument near
Forres, erected in memory of the defeat of the
Danes under Sweno. On that side of it which
fronts the south, and measures the thickness of
the obelisk about four feet above the pavement
on the top of the steps by which one ascends, is
an inscription disposed in two lines, on a scale
of fifteen inches in length. The Rev. Dr. Play-
fair reads it thus: LOIH in resi; and says it
composes the initials of the following words:
lege obelisci hujus Suenoglyphicis in nostro re-
gno extinctionem Suenone invasionis; which the
Dr. translates thus, 'understand that the hiero-
glyphics of this obelisk represent the extinction,
in our kingdom, of the invasion under Sweno.'
The monument was placed here, because the
Danes had attempted to form their settlement in
this quarter. Translated literally it signifies
'by the hieroglyphics of this obelisk, read the
extinction, in our kingdom, of the invasion under
Sweno.'

SWERD, *v. n.* See To SWARD. To breed a
green turf.

The clays that are long in swerding, and little
subject to weeds, are the best land for clover. *Mortimer.*

SWERTIA, or more properly SUERTIA; for,
it is monstrously unclassical to put W even into
a modern Latin word. To avoid such barbarism
the late Dr. Browne turned his name into
Bruno. Marsh Gentian, in botany, a genus of
plants belonging to the class of pentandria, and
to the order of digynia; and in the natural sys-
tem ranging under the twentieth order, rótaacea.
The corolla is wheel-shaped. There are necta-
liferous pores at the bases of the segments of the
corolla. The capsule is unilocular and bivalve.
There are six species; viz. 1. S. carinthiaca; 2.
corniculata; 3. dichotoma; 4. difformis; 5.
perennis; and 6. Rotata. S. perennis is a na-
tive of England. It is distinguished by radical
oval leaves. It flowers in August.

SWERVE, *v. n.* Saxon and Belg. *swerven*;
Swed. *swarfva*. To wander; rove; bend from
a straight course or direction; deviate; wind
round.

The ungodly have laid a snare for me; but yet I
swerve not from thy commandments. *Common Prayer.*

A maid thitherward did run,
To catch her sparrow which from her did swerve. *Sidney.*

That which angels do clearly behold, and without
any swerving observe, is a law celestial and heavenly. *Hooker.*

Were I the fairest youth
That ever made the eye swerve. *Shakspeare.*
Annihilation in the course of nature, defect and
swerving in the creature, would immediately follow. *Hakeuill.*

Till then his majesty had not in the least swerved
from that act of parliament. *Clarendon.*
Firm we subsist, yet possible to swerve. *Milton.*

The *swerving* vines on the tall elms prevail,
Unhurt by southern showers or northern hail.

Dryden.

She fled, returning by the way she went,
And *swerved* along her bow with swift ascent. *Id.*

Many who, through the contagion of an example,
swerve exceedingly from the rules of their holy faith,
yet would upon such an extraordinary warning be
brought to comply with them. *Atterbury's Sermons.*

SWIETEN. See VAN SWIETEN.

SWIETENIA, or more properly SUIETENIA, mahogany, in botany, a genus of plants belonging to the class of decandria, and to the order of monogynia; and in the natural system arranged under the fifty-fourth order, miscellanææ. The calyx is quinquefid. There are five petals; the nectarium is cylindrical, supporting the antheræ with its mouth. The capsule is five-celled, woody, and opening at the mouth. The seeds are imbricated and winged. There is only one species;

S. mahagoni, a native of the warmest parts of America, growing also in the island of Cuba, Jamaica, Hispaniola, and the Bahama Islands. It abounded formerly in the low lands of Jamaica, but it is now found only on hills and places difficult of access. It thrives in most soils, but varies in texture and grain according to the nature of the soil. On rocks it is of a smaller size, but very hard and weighty, of a close grain and beautifully shaded; while the produce of the low and richer lands is observed to be more light and porous, of a paler color and open grain; and that of mixed soils to hold a medium between both. The tree grows very tall and straight, and is usually four feet in diameter; the flowers are of a reddish or saffron color, and the fruit of an oval form, and about the size of a turkey's egg. The wood is generally hard, takes a fine polish, and is found to answer better than any other sort in all kinds of cabinet ware. It is said to be used sometimes in ship-building; a purpose for which it is remarkably adapted, if it were not too costly, being very durable, capable of resisting gun-shots, and burying the shots without splintering. The seed vessels are of a curious form, consisting of a large cone splitting into five parts, and disclosing its winged seeds, disposed in the regular manner of those of apocynum. The seeds, being winged, are dispersed on the surface of the ground, where some falling into the chinks of the rocks strike root; then creep out on the surface of it, and seek another chink, into which they creep and swell to such a size and strength, that at length the rock splits and is forced to admit of the root's deeper penetration; and with this little nutriment the tree increases to a stupendous size in a few years. The first use to which mahogany was applied in England was to make a box for holding candles for Dr. Gibbons, an eminent physician in the latter end of the seventeenth and beginning of the eighteenth century, who had a brother, a West India captain, who brought over some planks of this wood as ballast. The superior qualities of it being immediately discovered, it soon came into general use.

SWIFT, *adj. & n. s.* } Sax. *grift*. Quick;
SWIFTLY, *adv.* } moving far in a short
SWIFTNESS, *n. s.* } time; fleet; speedy;
rapid: the current of a stream: the adverb and noun substantive correspond.

Men of war, whose faces were like the faces of lions, and as *swift* as the roes upon the mountains.

1 *Chron.* xii. 8.

Let every man be *swift* to hear, slow to speak.

James i. 19.

Thou art so far before

That *swiftest* wing of recompense is slow

To overtake thee.

Shakspeare.

We may outrun

By violent *swiftness* that which we run at;

And lose by over-running.

Id. *Henry VIII.*

We imitate and practise to make *swifter* motions than any out of other muskets.

Bacon.

These move *swiftly*, and at great distance; but then they require a medium well disposed, and their transmission is easily stopped. *Id.* *Natural History*

Exulting, till he finds their nobler sense
Their disproportioned speed does recompense;

Then curses his conspiring feet, whose scent
Betrays that safety which their *swiftness* lent.

Denham.

To him with *swift* ascent he up returned.

Speed to describe whose *swiftness* number fails.

Id.

He can live in the strongest *swifts* of the water.

Walton.

Pleased with the passage, we slide *swiftly* on,

And see the dangers which we cannot shun.

Dryden.

Such is the mighty *swiftness* of your mind,

That, like the earth's, it leaves our sense behind.

Id.

Things that move so *swift* as not to affect the senses distinctly with several distinguishable distances of their motion, and so cause not any train of ideas in the mind, are not perceived to move.

Locke.

Thy stumbling foundered jade can trot as high

As any other Pegasus can fly;

So the dull eel moves nimbler in the mud,

Than all the *swift*-finned racers of the flood.

Dorset.

It preserves the ends of the bones from incalcescency, which they, being solid bodies, would contract from any *swift* motion.

Ruy.

Clouded in a deep abyss of light,

While present, too severe for human sight,

Nor staying longer than one *swift*-winged night.

Prior.

In decent order they advance to light;

Yet then too *swiftly* fleet for human sight,

And meditate too soon their everlasting flight. *Id.*

Mantiger made a circle round the chamber, and the *swift*-footed martin pursued him.

Arbutnot.

There too my son—ah once my best delight,

Once *swift* of foot, and terrible in fight.

Pope's Odyssey.

SWIFT, *n. s.* From the quickness of their flight; apus. A bird like a swallow; a martin.

Swifts and swallows have remarkably short legs, and their toes grasp any thing very strongly.

Derham.

SWIFT (Dr. Jonathan), a wit and classical writer of the English language, was born in Dublin, November 30th, 1667. His father was an attorney, and of a good family; but, dying poor, the expense of his son's education was defrayed by his friends. At the age of six young Swift

was sent to the school of Kilkenny, whence he removed in his fifteenth year to Trinity College, Dublin. So much did he despise the study of the old logicians, at that time held so indispensably necessary, that he was refused a degree on account of his ignorance of their writings, and obtained it afterwards through the interest of his friends, and 'by special favor,' as inserted in the college registry. He remained in the college nearly three years after this, little known or regarded. By scholars he was reckoned a block-head; and, as his circumstances would not permit him to keep company with persons of equal rank upon an equal footing, he lived much alone, and his time was employed in pursuing his course of reading in history and poetry. Yet, under this pressure, he conceived the first rude draught of the Tale of a Tub. In 1688, being by the death of Godwin Swift his uncle, who had chiefly supported him, left without subsistence, he went to consult his mother, who then lived in Leicester, about the future course of his life; and, by her direction, solicited the advice and patronage of Sir William Temple, whose father had lived in great friendship with Godwin Swift. Temple received him with great kindness, and was so much pleased with his conversation that he detained him two years in his house, and recommended him to king William, who offered to make him a captain of horse. This not suiting his disposition, and Temple not having it quickly in his power to provide for him otherwise, Swift left his patron (1694) in discontent: having previously taken his master's degrees at Oxford. He now resolved to enter into the church, where his first preferment was only £100 a-year, being the prebend of Kilroot in Connor; which some time afterwards, upon Sir William Temple's earnestly inviting him back to his house at Moorpark, he resigned. In 1699 Swift lost his patron Sir W. Temple, who left him a legacy in money, with the property of his MSS.; and, on his death-bed, obtained for him a promise from the king, of the first prebend that should become vacant at Westminster or Canterbury. Swift dedicated to the king the posthumous works with which he was entrusted, and for a while attended the court; but soon found it in vain. He was then invited by the earl of Berkeley to accompany him into Ireland, where he obtained the livings of Laracor and Rathbaggin, in the diocese of Meath; and soon afterwards invited over the unfortunate Stella, a young woman of the name of Johnson, whose life he contrived to embitter, and whose days, though he certainly loved her, we may confidently affirm that he shortened by his caprice. This lady is generally believed to have been the daughter of Sir W. Temple's steward, though it has been said that she was Sir William's own natural daughter, and Swift himself his natural son; and that a discovery of this relationship was the cause of Swift's otherwise unaccountable conduct to that excellent woman. This apology, however, seems worthy of no credit. But, be it as it may, it is certain that Sir William left her £1000; and that, accompanied by Mrs. Dingley, whose whole fortune amounted to an annuity of £27 for life, she went, in consequence of Swift's invitation, to Laracor. With these two ladies

he passed his hours of relaxation, and to them he opened his bosom; but they never resided in the same house, nor did he see either without a witness. In 1701 Swift published A discourse of the contests and dissensions in Athens and Rome. It was the only work which he ever expressly acknowledged. Early in the following spring king William died; and Swift, on his next visit to London, found queen Anne upon the throne. He was during the earlier part of the queen's reign of no party, but employed himself in discharging the duties of his function, and in publishing from time to time such tracts as he thought might be useful. In 1704 he published The Tale of a Tub; which, considered merely as a work of genius, is unquestionably the greatest which he ever produced; but the levity with which religion was thought to be there treated, raised up enemies to him among all parties, and eventually precluded him from a bishopric. From that period till 1708 he seems to have employed himself in solitary study; but he then gave successively to the public The sentiments of a Church of England man, the ridicule of astrology under the name of Bickerstaff, the Argument against abolishing Christianity, and the defence of the Sacramental Test. Soon after began the busy and important part of Swift's life. He was employed in 1710 by the primate of Ireland to solicit the queen for a remission of the first fruits and twentieth parts to the Irish clergy. This introduced him to Mr. Harley, afterwards earl of Oxford, who, though a whig himself, was at the head of the tory ministry, and in great need of an auxiliary so able as Swift, by whose pen he and the other ministers might be supported in pamphlets, poems, and periodical papers. In 1710 was commenced the Examiner, of which Swift wrote thirty-three papers, beginning his first on the 10th of November, 1711. In 1712 he published The Conduct of the Allies ten days before the parliament assembled; and soon afterwards, Reflections on the barrier Treaty. The purpose of these pamphlets was to persuade the nation to a peace, by showing that 'mines had been exhausted and millions destroyed' to secure the Dutch and aggrandise the emperor, without any advantage whatever to Great Britain. Though these two publications, together with his Remarks on the Bishop of Sarum's Introduction to the third Volume of his History of the Reformation, certainly turned the tide of popular opinion, and effectually promoted the designs of the ministry, the best preferment which his friends could venture to give him was the deanery of St. Patrick's, which he accepted in 1713. In the midst of his power and his politics, he kept a journal of his visits, his walks, his interviews with ministers, and quarrels with his servant, and transmitted it to Mrs. Johnson and Mrs. Dingley, to whom he knew that whatever befel him was interesting; but in 1714 an end was put to his power by the death of the queen, which broke down at once the whole system of tory politics, and nothing remained for him but to withdraw from persecution to his deanery. In the triumph of the whigs, Swift met with every mortification that a spirit like his could possibly be exposed to.

The people of Ireland were irritated against him beyond measure; and every indignity was offered him as he walked the streets of Dublin. Nor was he insulted by the rabble only, but persons of distinguished rank and character forgot the decorum of common civility to give him a personal affront. In this situation he retired from the world to discharge his duties as a clergyman, and attend to the care of his deanery. That no part of his time might lie heavy on his hands, he employed his leisure hours on some historical attempts relating to the change of the ministers and the conduct of the ministry; and completed the History of the four last years of queen Anne's reign, which had been begun in her lifetime, but which he never published. Of the work which bears that title, and is said to be his, Dr. Johnson doubts the genuineness; and it certainly is not such as we should have expected from a man of Swift's sagacity and opportunities of information. In 1716 he was privately married to Mrs. Johnson by Dr. Ashe, bishop of Clogher; but the marriage made no change in their situation, 'and it would be difficult to prove,' says lord Orrery, 'that they were ever afterwards together but in the presence of a third person.' The dean lived in a private manner, known and regarded only by his friends, till about 1720 that he published his first political pamphlet relative to Ireland, entitled A Proposal for the Universal Use of Irish Manufactures; which so roused the indignation of the ministry that they commenced a prosecution against the printer, which drew the attention of the public to the pamphlet, and at once made its author popular. Whilst he was enjoying the laurels which this work had wreathed for him, his felicity, as well as that of his wife, was interrupted by the death of Mrs. Van Homrigh, and the publication of his poem called Cadenus and Vanessa, which brought upon him much merited obloquy. With Mrs. Van Homrigh, he became acquainted in London during his attendance at court; and finding her possessed of genius, and fond of literature, he took delight in directing her studies, till he got, insensibly, possession of her heart. From being proud of his praise, she grew fond of his person; and, despising vulgar restraints, she made him sensible that she was ready to receive him as a husband. She had wit, youth, beauty, and a competent fortune to recommend her, and for a while Swift seems to have been undetermined whether or not he should comply with her wish. She had followed him to Ireland, where she lived in a house about twelve miles from Dublin; and he continued to visit her occasionally, and to direct her studies, as he had done in London; but with these attentions she was not satisfied, and at last sent to him a letter written with great ardor and tenderness, insisting that he should immediately accept or refuse her as a wife. His answer, which probably contained the secret of his marriage, he carried himself; and, having indignantly thrown it on the lady's table, instantly quitted the house, we believe, without speaking to her, and returned to Dublin to reflect on the consequences of his own conduct. These were dreadful. Mrs. Van Homrigh survived her disappointment but a few weeks;

during which time she cancelled a will that she had made in his favor, leaving him a large fortune of £8000 a-year; and ordered the poem to be published in which Cadenus had proclaimed her excellence and confessed his love. In 1724 his patriotism again burst forth, to obstruct the currency of Wood's halfpence, and his zeal was crowned with success. Wood had obtained a patent to coin £180,000 in halfpence and farthings for the kingdom of Ireland; and was about to turn his brass into gold, when Swift, finding that the metal was debased to an enormous degree, wrote letters under the name of M. B. Drapier, to show the folly of giving gold and silver for coin not worth a third part of its nominal value. A prosecution was carried on against the printer; and lord Carteret, then lord lieutenant, issued a proclamation, offering £300 reward for discovering the author of the fourth letter. The day after Swift brushed up to the lord lieutenant at a levee at the castle, and upbraided him in loud and petulant terms with persecuting a poor shop-keeper whose crime was an endeavour to save his country from ruin; when lord Carteret, who had listened with great composure to the whole speech, made this fine reply, in a line of Virgil:—

Res duræ, & regni novitas me talia cogunt
Moliri.

From this time Swift was considered by the populace as the champion, patron, and instructor of Ireland. In 1727 he returned to England; where, in conjunction with Pope, he collected three volumes of miscellanies; and the same year he sent into the world his Gulliver's Travels. Whilst he enjoyed the reputation of this work, he was suddenly called to a home of sorrow. Poor Stella was sinking into the grave; and, after a languishing decay of about two months, died in her forty-fourth year, January 28th, 1728. With her vanished all his domestic enjoyments; the severity of his temper increased; he drove his acquaintance from his table, and wondered why he was deserted. The fits of giddiness and deafness to which he had been subjected from his boyish years became more frequent and violent as he grew old. In 1736, while he was writing a satire, called the Legion Club, against the Irish parliament, he was seized with so dreadful a fit of his malady that he left the poem unfinished; and never after attempted a composition that required a course of thinking. From this time his memory gradually declined. In 1741 he became utterly incapable of conversation; and it was found necessary to appoint legal guardians to his person and his fortune. He now lost all sense of distinction. During next year a short interval of reason ensuing gave hopes of his recovery; but in a few days he sunk into lethargic stupidity, motionless, heedless, and speechless. After a year of total silence, however, when his housekeeper told him that the usual illuminations were preparing to celebrate his birth, he answered, 'It is all folly: they had better let it alone.' He at last sunk into a perfect silence, which continued till the 29th of October 1745, when he expired without a struggle, in his seventy-eighth year. By his will, dated May 1740, just before he ceased to

be a reasonable being, he left about £1200 in specific legacies; and the rest of his fortune, which amounted to about £11,000, to erect and endow an hospital for lunatics and idiots. He was buried in the most private manner, according to his will, in the great aisle of St. Patrick's cathedral.

SWIFT (Dean, esq.), a near relation of the dean, grandson to Godwin Swift, the dean's uncle, was born in Dublin, educated at the university there, and completed his studies at Oxford. He had a fine taste, wrote entertaining verses, and was esteemed a perfect master of the Greek and Roman classics. He published an Essay upon the Life, Writings, and Character of Dr. Jonathan Swift, 1755; 2. The eighth 4to. volume of the dean's works, 1765; and, 3. His Letters, in 2 vols., 1768. He died at Worcester in 1783.

SWIFT, in ornithology. See HIRUNDO.

SWILL, *v. a. & n. s.* Sax. *ƿilzan*. To drink luxuriously and grossly; wash; drench; inebriate: drink thus lavishly taken or poured down.

The wretched, bloody, and usurping boar,
That spoiled your summer fields and fruitful vines,
Swills your warm blood like wash, and makes his
trough

In your embowelled bosoms.

Shakspeare. Richard III.

As fearfully as doth a galled rock,
O'erhang and jutty his confounded base,
Swilled with the wild and wasteful ocean. *Shakspeare.*

I should be loth

To meet the rudeness and *swilled* insolence
Of such late wassailers.

Milton.

He drinks a *swilling* draught; and, lined within,
Will supple in the bath his outward skin. *Dryden.*
Give swine such *swill* as you have. *Mortimer.*

With that a German oft has *swilled* his throat,
Deluded that imperial Rhine bestowed
The generous rummer.

Philips.

The most common of these causes are an hereditary disposition, and *swilling* down great quantities of cold liquors.

Arbuthnot.

Such is the poet, fresh in pay,
The third night's profits of his play;
His morning draughts till noon can *swill*,
Among his brethren of the quill.

Swift.

Thus as they swim in mutual *swill*, the talk
Reels fast from theme to theme.

Thomson.

SWIM, *v. n., v. a., &* } *Pret.* swam, swom,
SWIMMER, *n. s.* [*n. s.*] } or swum. Sax. *ƿim-*
SWIMMINGLY, *adv.* } man; Belg. *swimmen*.
To move or float on the water; be conveyed by water; glide along; be floated; be dizzy; to flow in any thing; hence, have abundance of a thing: to pass by swimming: the bladder of a fish: a swimmer is one who swims: swimmingly is, smoothly: without obstruction.

The soldiers' counsel was to kill the prisoners, lest any of them should *swim* out and escape.

Acts xxvii. 42.

The rest, driven into the lake, were seeking to save their lives by *swimming*; they were slain in coming to land by the Spanish horsemen, or else in their *swimming* shot by the harquebusers.

Knolles.

I will scarce think you have *swam* in a gondola.

Shakspeare.

Leap in with me into this angry flood,
And *swim* to yonder point.

Id. Julius Cæsar.

She with pretty and with *swimming* gate
Following, her womb then rich with my young
squire,

Would imitate.

Shakspeare.

We have ships and boats for going under water,
and brooking of seas; also *swimming*-girdles and supporters.

Bacon.

Birds find ease in the depth of the air, as *swimmers* do in a deep water.

Id.

With tenders of our protection of them from the fury of those who would soon drown them, if they refused to *swim* down the popular stream with them.

King Charles.

They now *swim* in joy,
Ere long to *swim* at large, and laugh; for which
The world a world of tears must weep.

Milton.

Animals *swim* in the same manner as they go, and need no other way of motion for natation in the water, than for progression upon the land.

Broune's Vulgar Errors.

Latrostrous and flat-billed birds being generally *swimmers*, the organ is wisely contrived for action.

Broune.

The frighted wolf now *swims* among the sheep,
The yellow lion wanders in the deep:
The stag *swims* faster than he ran before.

Dryden.

I *swoom* with the tide, and the water under me was buoyant.

Id.

A hovering mist came *swimming* o'er his sight,
And sealed his eyes in everlasting night.

Id.

I am taken with a grievous *swimming* in my head,
and such a mist before my eyes that I can neither hear nor see.

Id.

Sometimes he thought to *swim* the stormy main,
By stretch of arms the distant shore to gain.

Id.

My slack hand dropt, and all the idle pomp,
Priests, altars, victims *swam* before my sight!

Smith.

The braces have the nature and use of tendons, in contracting the *swim*, and thereby transfusing the air out of one bladder into another, or discharging it from them both.

Grew.

When the heavens are filled with clouds, when the earth *swims* in rain, and all nature wears a lowering countenance, I withdraw myself from these uncomfortable scenes into the visionary worlds of art.

Addison's Spectator.

John got on the battlements, and called to Nick,
I hope the cause goes on *swimmingly*.
The fainting soul stood ready winged for flight,
And o'er his eye-balls *swam* the shades of night.

Pope.

Sudden the ditches swell, the meadows *swim*.

Thomson.

Life is oft preserved
By the bold *swimmer*, in the swift illapse
Of accident disastrous.

Id.

SWIMMING, the art of suspending one's self on water, and at the same time making a progressive motion through it. Although swimming is not natural to man, yet there are no nations so barbarous but the art is known among them, even in greater perfection than among civilised people. It is probable, therefore, that the art, though not absolutely natural, will always be acquired by people in a savage state from imitating the brutes, most of whom swim naturally. The theory of swimming depends upon this simple principle: that if a force is applied to any body, it will always move towards that side where there is the least resistance. This is evident in the motion of vessels: and the same thing takes place in swimming, whether the au-

mal be man, quadruped, bird or fish. When a man swims, he strikes the water with his hands, arms, and feet; in consequence of which the body moves in a direction contrary to the stroke. Upon this principle, and on this only, a man may either ascend, descend, or move obliquely, in any possible direction in the water. It is incredible what expert swimmers will perform in this way; of which Mr. Forster gives a remarkable instance in the inhabitants of Otaheite; whose agility was such, that when a nail was thrown overboard, they would jump after it into the sea, and never fail to catch it before it came to the bottom. As to the practice of swimming, few directions can be given. The great obstacle is the natural dread which people have of being drowned; and this it is impossible to overcome by any thing but practice and habit. With regard to the real danger of being drowned, it is but little, and arises entirely from terror. Dr. Franklin observes, '1st. That though the legs, arms, and head, of a human body, being solid parts, are specifically heavier than fresh water, yet the trunk, particularly the upper part, from its hollowness, is so much lighter than water, as that the whole of the body, taken together, is too light to sink wholly under water, but some part will remain above until the lungs become filled with water: which happens from drawing water into them instead of air, when a person in the fright attempts breathing while the mouth and nostrils are under water. 2dly, That the legs and arms are specifically lighter than salt water, and will be supported by it; so that a human body would not sink in salt water though the lungs were filled as above, but from the greater specific gravity of the head. 3dly, That therefore a person throwing himself on his back in salt water, and extending his arms, may easily lie so as to keep his mouth and nostrils free for breathing; and by a small motion of his hands may prevent turning, if he should perceive any tendency to it. 4thly, That in fresh water, if a man throws himself on his back near the surface, he cannot long continue in that situation, but by a proper action of his hands on the water. If he uses no such action, the legs and lower part of the body will gradually sink till he comes to an upright position; in which he will continue suspended, the hollow of the breast keeping the head uppermost. 5thly, But if in this erect position the head is kept upright above the shoulders, as when we stand on the ground, the immersion will, by the weight of the part of the head that is out of the water, reach above the mouth and nostrils, perhaps a little above the eyes; so that a man cannot long remain suspended in water with his head in that position. 6thly, The body continuing suspended as before, and upright, if the head be leaned quite back, so that the face looks upwards, all the back part of the head being then under water, and its weight consequently in a great measure supported by it, the face will remain above water quite free for breathing, will rise an inch higher every inspiration, and sink as much every expiration, but never so low as that the water may come over the mouth. 7thly, If, therefore, a person unacquainted with swimming, and falling acci-

dentally into the water, could have presence of mind to avoid struggling and plunging, and to let the body take this natural position, he might continue long safe from drowning, till, perhaps, help would come; for, as to the clothes, their additional weight, while immersed, is very considerable, the water supporting it; though, when he comes out of the water, he would find them very heavy indeed.' The doctor's method of learning to swim is as follows:—The person must walk into water so deep that it will reach to the breast. He is then to lie down gently on the belly, keeping the head and neck perfectly upright, the breast advancing forward, the thorax inflated, and the back bent; then, withdrawing the legs from the bottom, and stretching them out, strike the arms forward in unison with the legs. Swimming on the back is somewhat similar to that on the belly; but with this difference, that, although the legs are employed to move the body forwards, the arms are generally unemployed, and the progressive motion is derived from the movement of the legs. In *diving*, a person must close his hands together, and, pressing his chin upon his breast, make an exertion to bend with force forwards. While in that position, he must continue to move with rapidity under the surface; and, whenever he wishes to return to his former situation, he has nothing to do but bend back his head, and he will immediately return to the surface. It is very common for novices to use corks or bladders to assist in keeping the body above the water. Dr. Franklin allows that they may be of service for supporting the body while one is learning what is called the stroke, or that manner of drawing in and striking out the hands and feet that is necessary to produce progressive motion. 'But,' says he, 'you will be no swimmer till you can place confidence in the power of the water to support you: I would, therefore, advise the acquiring that confidence in the first place, especially as I have known several who, by a little of the practice necessary for that purpose, have insensibly acquired the stroke, taught as it were by nature. The practice I mean is this:—Choosing a place where the water deepens gradually, walk coolly into it till it is up to your breast: then turn round your face to the shore, and throw an egg into the water between you and the shore; it will sink to the bottom, and be easily seen there, if the water is clear. It must lie on the water so deep as that you cannot reach it to take it up but by diving for it. To encourage yourself to do this, reflect that your progress will be from deeper to shallower water; and that at any time you may, by bringing your legs under you, and standing on the bottom, raise your head far above the water: then plunge under it with your eyes open, throwing yourself towards the egg, and endeavouring, by the action of your hands and feet against the water, to get forward till within reach of it. In this attempt you will find that the water buoys you up against your inclination, and it is not so easy a thing to sink as you imagined; that you cannot but by active force get down to the egg. Thus you feel the power of the water to support you, and learn to confide in that power; while your endeavours to overcome it,

and to reach the egg, teach you the manner of acting on the water with your feet and hands; which action is afterwards used in swimming to support your head higher above water, or to go forward through it.' Many other rules have been laid down for acquiring this; but, if a young man once gets rid of fear, these are sufficient, and by practice he may soon acquire various evolutions; or he may find a full account of these in the *Encyclopedie Methodique*.

SWIMMING OF FISH. A great proportion of the inhabitants of the waters have an air-bladder, by which they poise themselves. Their movements chiefly depend upon their tail. See **ICHTHYOLOGY** and **ZOOLOGY**.

SWINDON, a market-town and parish in Kingsbridge hundred, Wilts., situate on an eminence, ten miles north from Marlborough, and eighty-three from London; containing 272 houses and 1580 inhabitants. This is a neat town, and the houses are well built of stone. The church is neatly fitted up in its interior. Here is a free-school for boys and girls, and in the vicinity of the town are some excellent stone quarries. Market on Monday. Fairs, Monday before April 5th, second Monday after May 11th, September and October. It is a vicarage, value £17.

SWINE, *n. s.* † Sax. *ƿin*; Belg. *swyn*; Goth. *SWINEHERD* † and Swed. *swin*. Probably the plural of some old word, but now the same in both numbers. A hog; a pig: a keeper of hogs.

There *swineherd*, that keepeth the hog. *Tusser*.
O monstrous beast! how like a *swine* he lies!

Shakspeare.

Now I fat his *swine*, for other's cheere. *Chapman*.

Who knows not Circe,

The daughter of the Sun? whose charmed cup
Whoever tasted, lost his upright shape,
And downward fell into a grovelling *swine*. *Milton*.

Had the upper part, to the middle, been of human shape, and all below *swine*, had it been murther to destroy it? *Locke*.

How instinct varies in the grovelling *swine*,
Compared, half-reasoning elephant, with thine!

Pope.

The whole interview between Ulysses and Eumeus has fallen into ridicule: Eumeus has been judged to be of the same rank and condition with our modern *swineherds*. *Broome*.

SWINE, in zoology. See **Sus**.

SWINE, in geography, a branch of the Oder, anciently called *Suevus*.

SWINE-GRASS, or **SWINE CRESS**. See **COCHLEARIA**.

SWINE'S CRESS, a species of *cochlearia*.

SWINE-STONE, *lopis suillus*, or fetid stone, so called from its excessively fetid smell, is a species of saline stone. It is found, 1. Solid, with the particles scarcely visible, of a black color; as the marble of Flanders and Jutland. 2. With visible grains of a blackish-brown color, found in Sweden. 3. With coarse scales, found also in Sweden. Many of the limestones found in England belong to this species, and emit a very fetid smell when struck violently; but it goes off in the fire. See **MINERALOGY**.

SWINESHEAD, a market-town and parish in Kirton hundred, parts of Holland, Lincolnshire, six miles south-west of Boston, and 113 north-

east of London; containing 345 houses and 1695 inhabitants. Market on Thursday. Fairs, first Thursday in June and second in October.

SWING, *v. n.*, *v. a.*, & *n. s.* Sax. *ƿingian*. To wave to and fro loosely: whirl around in the air; wave loosely: motion of this kind, or the influence or power that moves; course; liberty; unrestrained tendency; sweep.

Where the *swing* goeth, there follow, fawn, flatter, laugh, and lie lustily at other men's liking.

Ascham's Schoolmaster.

His sword prepared,
He *swang* about his head, and cut the winds.

Shakspeare.

The ram that batters down the wall,
For the great *swing* and rudeness of his poise,
They place before his hand that made the engine.

Id.

Take bottles and *swing* them: fill not the bottles full, but leave some air, else the liquor cannot play nor flower.

Bacon.

In casting of any thing, the arms, to make a greater *swing*, are first cast backward.

Id. Natural History.

Facts unjust

Commit, even to the full *swing* of his lust.

Chapman.

Swing thee in the air, then dash thee down,
To the hazard of thy brains, and shattered sides.

Milton.

Those that are so persuaded, desire to be wise in a way that will gratify their appetites, and so give up themselves to the *swing* of their unbounded propensions.

Glanville.

Swinging a red hot iron about, or fastening it unto a wheel under that motion, it will sooner grow cold.

Broune.

In this encyclopædia, and round of knowledge, like the great wheels of heaven, we are to observe two circles, that, while we are daily carried about, and whirled on by the *swing* and rapt of the one, we may maintain a natural and proper course in the sober wheel of the other.

Id.

The descending of the earth to this orbit is not upon that mechanical account Cartesius pretends, namely, the strong *swing* of the more solid globuli that overflow it.

More.

I tried if a pendulum would *swing* faster, or continue *swinging* longer in our receiver, in case of extraction of the air than otherwise.

Boyle.

If one approach to dare his force,
He *swings* his tail, and swiftly turns him round.

Dryden.

Take thy *swing*:

For not to take is but the self-same thing. *Id.*

Men use a pendulum, as a more steady and regular motion than that of the earth; yet, if any one should ask how he certainly knows that the two successive *swings* of a pendulum are equal, it would be very hard to satisfy him.

Locke.

Were it not for these, civil government were not able to stand before the prevailing *swing* of corrupt nature, which would know no honesty but advantage.

South.

These exuberant productions only excited and fomented his lusts; so that his whole time lay upon his hands, and gave him leisure to contrive, and with full *swing* pursue his follies.

Woodward.

If the coach *swung* but the least to one side, she used to shriek so loud, that all concluded she was overturned.

Arbutnot.

Jack hath hang'd himself: let us go see how he *swings*.

Id.

When the *swinging* signs your ears offend
With creaking noise, then rainy floods impend.

Gay.

Let them all take their *swing*
To pillage the king,
And get a blue ribband instead of a string. *Swift*.

SWINGE, *v. a. & n. s.* } Sax. *ƿpincan*. To
SWINGEBUCKLER, *n. s.* } whip; bastinado;
SWINGING, *adj.* } punish; flourish
SWINGINGLY, *adv.* } about: a sweep or
way: a swingebuckler is a bully: swinging,
sweeping; huge; great; a low word: the adverb
corresponding.

You had not four such *swingebucklers* in all the
inns of court again. *Shakspeare. Henry IV.*

Sir, I was in love with my bed: I thank you,
you *swinged* me for my love, which makes me the
bolder to chide you for your's.

Id. Two Gentlemen of Verona.

He, wroth to see his kindom fail,
Swinges the scaly horror of his folded tail. *Milton*.

The shallow water doth her force infringe,
And renders vain her tail's impetuous *swinge*.
Waller.

This very reverend letcher, quite worn out
With rheumatism, and crippled with his gout,
Forgets what he in youthful times hath done,
And *swinges* his own vices in his son.

Dryden, jun. Juvenal.

The countrymen, seeing the lion disarmed, with a
swinging cudgel broke off the match. *L'Estrange*.

A good *swinging* sum of John's readiest cash went
towards building of Hocus's country-house.

Arbuthnot.

The printer brought along with him a bundle of
those papers, which, in the phrase of the whig-
coffee-houses, have *swinged* off the Examiner.

Swift.

Henceforward he'll print neither pamphlets nor
linen,
And, if swearing can do't, shall be *swingingly*
mauled. *Id.*

SWINGING, a kind of exercise strongly recom-
mended to persons in consumption by some
physicians, and disapproved of by others. See
MEDICINE.

SWING-TREE of a waggon is the bar fast-
ened across the fore-guide to which the traces of
the horses are fastened.

SWING-WHEEL, in a royal pendulum, that
wheel which drives the pendulum. In a watch
or balance clock it is called the crown-wheel.

SWINK, *v. n., v. a., & n. s.* Sax. *ƿpincan*.
To labor; toil; drudge: to over-labor: such
labor; drudging. Obsolete.

Riches, renown, and principality,
For which men *swink* and sweat incessantly.

Spenser.

Ah, Piers, been thy teeth on edge, to think
How great sport they gaynen with little *swinke*? *Id.*

Thou's but a lazy loorde,
And rekes much of thy *swinke*. *Id.*

The laboured ox
In his loose traces from the furrow came,
And the *swinked* hedger at his supper sat. *Milton*.

SWINNA, an island of Scotland, in the Pent-
land Frith, one mile long and half a mile broad,
inhabited by six families, and about twenty-two
souls, who live chiefly by piloting vessels through
the dangers of the frith, and the whirlpools, called
the Wells of Swinna.

SWINTON (John), a very celebrated English

antiquary, the son of John Swinton of Bexton,
gent, was born in Cheshire in 1703. His pa-
rents were not affluent, as he was entered at
Oxford as a Servitor at Wadham College in
October, 1719. On June 30, 1723, he was
elected a scholar on a Cheshire foundation. In
December, 1723, he became B. A., and on De-
cember 1, 1726, M. A. He was ordained deacon
May 30, 1725; priest May 28, 1727; and made
rector of St. Peter le Bailey in Oxford in Febru-
ary, 1728. In June 1728 he was elected a fel-
low of his college; but willing to see the world,
he accepted of a chaplainship to the English fac-
tory at Leghorn. But as he did not enjoy his
health he went to Florence in April 1733, where
he attended Mr. Coleman, the English envoy, in
his last moments. He returned through Venice
and Vienna, and visited Presburg in Hungary.
While he was abroad he was admitted into some
foreign societies; viz. the Academy degli Apa-
tisti at Florence, and the Etruscan Academy of
Cortona. On his return he settled at Oxford,
where he became chaplain to the gaol. He mar-
ried in 1743 and gave up his fellowship. In
1759 he became B. D.; in 1767 he was elected
custos Archivorum; and, on April 4th, 1777, he
died without issue. His wife died in 1784, and
both were buried in the chapel of Wadham Col-
lege. His publications were numerous and
learned. He published, 1. *De Lingua Etruriae*
Regalis vernacula Dissert. 4to. 19 p. Oxon, 1738.
2. *A Critical Essay on the Words Διαμων and*
Δαιμωνιον, 8vo. London, 1739. 3. *De priscis*
Romanorum literis, 4to. 20 p. Ox. 1746. 4. *De*
Primogenio Etruscorum Alphabeto, Ox. 1746.

chols, in a paper printed in the Gentleman's Magazine for December, 1784. The original is deposited in the British museum. It assigns the following divisions of the history to Mr. Swinton:—The history of the Carthaginians, Numidians, Mauritians, Gætulians, Garamantes, Melano-Gætulians, Nigritiæ, Cyrenaica, Marmorica, the Regio Syrtica, Turks, Tartars, and Moguls, Indians, and Chinese; a Dissertation on the Peopling of America, and one on the Independence of the Arabs.

SWITCH, *n. s. & v. a.* Isl. and Swed. *swig.*
A small flexible twig: to lash; jerk.

Fetch me a dozen crabtree staves, and strong ones; these are but *switches*. *Shakspeare. Henry VIII.*

Lay thy bridle's weight
Most of thy left side; thy right horse then *switching*,
all thy throat

Spent in encouragements give him; and all the rein
let float. *Chapman's Iliad.*

When a circle 'bout the wrist
Is made by beadle exorcist,
The body feels the spur and *switch*. *Hudibras.*

Mauritaniâ, on the fifth medal, leads a horse with something like a thread; in her other hand she holds a *switch*. *Addison*

SWITZERLAND, a delightful country in the interior of Europe, bounded on the west by France, on the south by Italy, on the north and east by Germany. It extends from east to west nearly 200 miles, and from north to south about 140. Its form is a medium between an oblong and an oval; and, though the limits of its circumference are irregular, it is on the whole compact. Various have been its modern territorial changes and arrangements; but it was recognised by the congress of Vienna, in 1815, as consisting of twenty-two cantons of the following extent and population:—

Cantons.	Extent. Square miles.	Population.	Chief Towns.	
				Population.
Zurick	960	224,150	Zurick	10,470
Berne	3,690	356,710	Berne	13,000
Lucerne	768	105,560	Lucerne	5,000
Uri	512	13,930	Altorf	3,000
Schwitz	470	96,040	Schwyz	4,640
Unterwalden	260	23,150	Sarnen	3,000
Glarus	453	28,000	Glarus	3,000
Zug	125	14,710	Zug	2,500
Fryburg	490	67,814	Fryburg	6,460
Solothurn	277	54,380	Solothurn	4,100
Basle	266	55,330	Basle	16,200
Schaffhausen	170	28,050	Schaffhausen	5,500
Appenzell	223	57,510	Herisau	7,000
St. Gall	853	157,700	Appenzell	3,000
Gray League	2,986	98,090	St. Gall	9,000
Aargau	768	152,900	Chur	3,350
Thurgau	357	89,845	Aargau	3,000
Tessino	1,183	103,950	Frauenfeld	1,500
Vaud or Waadt	1,493	178,880	Lugano	3,400
Vallois or Wallis	1,962	77,570	Lausanne	9,960
Neufchatel	320	56,640	Sitten or Sion	2,500
Geneva	95	53,560	Neufchatel	5,150
			Geneva	22,000
	18,681, or 11,955,840 acres	2,037,030		

Each of the cantons has its own system of government; out they all form a general community, by means of representatives chosen from each, who meet to regulate the external relations of the union, and to provide the means, in troops and money, for the common defence; assembling yearly in July, or more frequently, on the requisition of any five of them. Treaties of peace, or declarations of war, require the assent of three-fourths of the votes. All other matters are determined by majority. The place of meeting is in rotation, Zurich, Berne, and Lucerne, each for two years, where the supreme court is held, and the chancellor and state-secretary hold their offices. The expenses of the general government are defrayed by contributions from each canton, according to their estimated wealth, which, as well as the military contingent, is adjusted every period

of twenty years. The revenues, expenses, and debts of the cantons are generally kept as a kind of state secret; and the taxes are various, but, in general, very light.

Every man capable of bearing arms is occasionally trained and exercised, but a more permanent force is arranged, to which each of the cantons must furnish their proportion, at the rate of two men out of every hundred of the proper age. These form an army of nearly 34,000 men, as follows:—

Artillery	32 companies	2,272 men.
Sappers	2 ditto	142
Pontoniers	1 ditto	71
Train		1,400
Light cavalry	17 troops	1,088
Sharpshooters	10 companies	1,000
Infantry	204 ditto	25,199
		2 Q

Yagars . . . 2 companies 2,000 men.
Staff corps 586

A militia, mustered under the direction of each individual canton, amounts also to 67,516 men, besides the landwehr, or levy en masse, which comprehends the whole of the male population. To cherish the military spirit, the cantons permit great numbers of their young men to enter into the service of foreign states. In 1816 the numbers so engaged were estimated at 30,000; of whom 12,370 were in France; 10,000 in the Netherlands; 430 in Prussia; and the others in Spain and Sardinia.

Lucerne, Uri, Schwitz, Unterwalden, Zug, Fryburg, Solothurn, Tessino, and a part of Appenzell, still adhere to the Roman Catholic religion. Protestantism is established in Zurich, Berne, Basle, Schaffhausen, Vaud, Neuchâtel, Geneva, and a part of Appenzell: and both religions in Glarus, Thurgau, Aargau, St. Gall, and the Gray League, but here the majority of the people are Protestants. The number of the Reformed or Calvinists are estimated to be 1,046,000; of the Catholics 682,000; in the remainder are comprised a few Jews, Lutherans, and Baptists.

Switzerland, the most mountainous country in Europe, is largely occupied by various branches of the Alps. The only extensive tract of vales, with mountains of more moderate height, is to the westward, in the cantons of Bale, Zurich, and part of Berne; but even here the frontier is formed by mountains, the Jura ridge extending in a long line from north to south. The most remarkable valley of Switzerland is that of the Rhone; being at once the widest, and surrounded by the highest mountains. The Alps vary in height from 5000 to 8000, 10,000, and even 15,000 feet. After Mont Blanc, computed at 15,500 feet, comes Monte Rosa, 14,200 feet. Mount St. Gothard, the great St. Bernard, and the Simplon, well known as the route of travellers, are still not equal in height to several mountains of the interior, such as Mont Cervin, 13,800 feet; the Jungfrau-horn, the Tursteraarhorn, the Furca, Schreckhorn, each nearly 14,000 feet; the Wetterhorn and Gallenstock, between 11,000 and 12,000, &c. Toward their base the Alps exhibit every variety of temperature and product; rich corn fields or luxuriant pastures extending along the lower part of many of them. The middle consists of pastures less productive, but containing a great variety of plants; while the summits are composed of rocks, craggy, inaccessible, devoid of vegetation, and covered with enormous masses of ice and snow. In some parts the transition from pasture to sterility takes place very gradually; in others it is more rapid. Every mountain has its rivulets, which dash from rock to rock, and frequently its beautiful cascades. At Staubach, in the valley of Lauterbronnen, in the canton of Berne, is a stream which precipitates itself over a rock of nearly 1000 feet. Other parts offer a transition from scenes bleak and savage to landscapes of luxuriant verdure.

Switzerland is less remarkable for its minerals than might be expected. Iron, however, is found in several parts, particularly in the district of Sargans, in the east; and there are mines, or

rather quarries, of rock salt in the canton of Berne. Mines of silver, copper, and lead, are also found in different parts; but they do not repay the labor of working. Marble, porphyry, alabaster, crystal, and sulphur, are found occasionally: of mineral waters the most considerable are those of Leuck and Schintznach, and the warm baths of Pfeffers. The glaciers, or lakes of frozen snow, accumulated to a vast height, or rather depth, are found first at about 8000 or 9000 feet above the sea; although, in a winter of unusual rigor, their ramifications extend considerably lower. Their surface, in some cases smooth and unbroken, is in others marked by deep chasms and pinnacles rising in fantastic forms, and presenting to the eye the appearance of a city of crystal. In the long alpine range, extending along the south of Switzerland, from Mont Blanc in the west, to the extremity of Tyrol in the east, are reckoned no less than 400 of these glaciers, differing greatly in magnitude, but frequently extending from sixteen to eighteen miles in length by one or two in breadth. The latter can with difficulty be ascertained, but is supposed to vary from 100 to 600 feet; the total extent of their surface has been calculated at 1000 square miles. Bourrit's description of one of these magnificent scenes is as follows:—'At length,' says he, 'we perceived through the trees a mountain of ice as splendid as the sun, and flashing a similar light on the environs. The first aspect of the glacier of the Rhone inspired us with great expectation. A moment afterwards, this enormous mass of ice having disappeared behind thick pines, it soon after met our sight between two vast blocks of rock, which formed a kind of portico. Surprised at the magnificence of this spectacle, and at its admirable contrasts, we beheld it with rapture. At length we reached this beautiful portico, beyond which we were to discover all the glacier. We arrived; at this sight, one would suppose one's self in another world; so much is the imagination impressed with the nature and immensity of the objects. To form an idea of this superb spectacle, figure in your mind a scaffolding of transparent ice, filling a space of two miles, rising to the clouds, and darting flashes of light like the sun. Nor were the several parts less magnificent and surprising. One might see, as it were, the streets and buildings of a city, erected in the form of an amphitheatre, and embellished with pieces of ice, cascades, and torrents. The effects were as prodigious as the immensity and the height. The most beautiful azure, the most splendid white, the regular appearance of a thousand pyramids of ice, are more easy to be imagined than described. Such is the aspect of the glacier of the Rhone, reared by nature on a plan which she alone can execute; we admire the majestic course of the river without suspecting that what gives it birth and maintains its waters, may be still more majestic and magnificent.'

No country is better provided with water, particularly in summer, when the melting of the snow affords a copious supply. The Rhone, rising in the centre of Switzerland, holds a westerly course through a beautiful valley, and pours into the lake of Geneva a stream which, turbid at

its influx, becomes pure and transparent when reissuing from the lake. The Ticino collects the waters flowing from Mount St. Gothard and the Alps, which look towards Lombardy. The Aar, rising on the northern slope of the central Alps, receives numberless streams flowing towards the western or more level parts of Switzerland; while the Rhine, holding at first a north-east course, encircles a part of the cantons, flows through the lake of Constance and Zell, and receives successively the Thur, the Limmat, the Reuss, and the Aar, which, joined to its own waters, render it, ere quitting the Swiss territory, the second river in Europe. The lakes of Switzerland are also numerous: the principal are those of Geneva, Constance, Neufchatel, Bienne, Zurich, Wallenstadt, Walstadter or Lucerne, Thun, and Brientz; most of them navigable. On this account a number of the towns of Switzerland are situated on their sides; and the mountains, rising from the shore in an amphitheatre form, render the scenery beautifully romantic.

The valleys of Switzerland and the bases of the mountains enjoy the warmth of an Italian sun, where their ascent discovers a scanty vegetation, and the summit is doomed to all the rigors of an Arctic winter. Such a contrast is not, however, exhibited in the northern or level part of the country, where the climate differs little from that of the south of Germany. In winter, however, the degree of cold is greater in the valleys of Switzerland, than in most parts of France or Germany, in consequence, doubtless, of the accumulation of snow and ice on the adjacent mountains; and stormy weather frequently occurs.

In travelling through this country one is constantly surprised at the care bestowed on the most unpromising spots; and at seeing vines, corn, and rich pasturages, where at one time there can have been little else than naked rocks. The products are wheat, barley, oats, maize, flax, hemp, and tobacco: the fruits of frequent occurrence, vines, chestnuts, prunes, peaches, walnuts, cherries; in the colder situations, apples and pears; and in the southern valleys the almond and fig. Wood, both for building and fuel, is found in most parts: but the corn raised is considerably below the consumption; and bread is by no means of universal use. The breeding of cattle, a branch of industry pointed out by the abundance of pasture, and the difficulties attending tillage, forms the grand source of national subsistence: the herds are driven to the mountains in spring, and graze there until the approach of winter forces them to descend; cheese, butter, allow, hides, form the chief articles of export. After cattle, the animals chiefly raised are goats, sheep, and hogs. The summits of the Alps are occupied by the chamois, wild goat, white and red fox, and a kind of hare, which, in summer, resembles the hare of Britain, but in winter becomes white.

Switzerland has on the whole a fair share of trade. The conveyance of goods along the Aar, the Reuss, and the Rhine, facilitates its intercourse with Germany and the Netherlands; and the Rhone, though more difficult of navigation, serves the same purpose in regard to

France: the exports are linen, cotton cloth, woollens, and, in a small degree, silks; also cattle, sheep, hides, tallow, butter, and cheese; the chief imports, corn from Germany, salt from Tyrol and Franche Comte; spices, dyewoods, groceries, and other colonial produce from Holland; raw silk from Italy, and manufactured articles (such as hardware and cotton yarn), from England. The manufactures are linen, lace, thread, and woollens, and are of old standing; cottons have been introduced, or at least extended, since the latter part of the eighteenth century; leather gloves, silks, porcelain, pottery, toys, tobacco, and snuff, are made in various places; and clocks and watches have long been staple articles at Geneva and Neufchatel.

The universities of Geneva and Basle have long been distinguished. There are, besides, academies or colleges at Zurich, Berne, and Lausanne, and schools of good repute in various towns, in particular Neufchatel, Schaffhausen, and St. Gall; also at Coire, the small sequestered capital of the Grisons. Among literary associations are to be mentioned the Helvetic society of Bale, the physical of Zurich, and the economical of Berne. In regard to improvements in education, it suffices to mention the names of Pestalozzi and Fellenberg, both inhabitants of Switzerland: nor is there any reluctance here to borrow improvements from other countries, the method of Bell and Lancaster having been introduced in several places.

The Swiss were anciently called Helvetii, and the country Helvetia, whence the modern name of the Helvetic Republic. The ancient Helvetians were a Gaulish or Celtic people, and Helvetia was divided into four cantons or territories. Julius Cæsar was the first who reduced the inhabitants under the dominion of the Romans, and these founded colonies here under the names of Julia Equestris, Augusta Raurocorum, and Aventicum. Their dominion continued till the fifth century, when the country was overrun by the Burgundians and Germans; but soon after the Franks made themselves entire masters of it. On the decease of Louis I., king of the Franks and emperor of the Romans, the south part of Helvetia, or Burgundy, devolved to the emperor Lotharius, and the north, or that of Alemain, to king Louis the German. Lotharius II., son to the former and king of Austrasia, retained the south part of Helvetia, which, together with Burgundy, or Franche Comte, was styled the Lesser Burgundy. After his demise this south part also devolved to Louis the German, who thus became possessed of all Switzerland, and from him it descended to his son Charles the Fat. In 888 Rodolphus, duke of the Lesser Burgundy, took on him the title of king, but the north part of Switzerland continued under the dominion of the emperor Arnolphus. Rodolphus II., son to the former, obtained a grant of the Argau from the emperor Henry I. This prince was succeeded by his son Conrad, as the latter was by his son Rodolphus III., who, in 1032, by a formal will, bequeathed his kingdom of the Lesser Burgundy to the emperor Conrad II., whereby all Switzerland once more became united to the German empire. In the thirteenth century it became a

third time a nominal province of the German empire, which, however, was possessed of little real authority here. A great part of the country was in the hands of the clergy, and the remainder in general of particular nobles. The inhabitants of Uri, Schwitz, Unterwald, and the territory of Hasli, were, from time immemorial, possessed of the right of being governed by their own magistrates, with other important privileges; and, in the twelfth century, the first three entered into an alliance which they solemnly renewed every tenth year. They had always declared themselves averse to the authority of the emperor's stadtholder in Switzerland, till, in 1209, Otho IV. compelled them to receive Rodolphus III., count of Habsburg, as his representative, though he was to take an oath that he would govern according to law and equity, and make no encroachments upon their rights and liberties. This nobleman seems to have been little observant of that engagement; for, in 1231, we find them unanimously addressing the emperor, Henry VII., to recall him; which he accordingly did, farther confirming to them all their privileges. In 1249 the like was done by his successor Frederick. In 1257, during the interregnum, in consideration of his great power, they chose for their protector Rodolphus V. count of Habsburg, who, in 1273, became emperor of Germany. At the solicitation of his son Albert, duke of Austria, he intended to have erected a particular dukedom in Switzerland, which design did not transpire till several years after, when it appeared that he had purchased of the abbot of Murbach the town of Lucern, with his revenues, and prerogatives in several villages in the territory of Schwitz. These three districts, on the death of Rodolphus, faithfully adhered to his successor the emperor Adolphus, which gave so much offence to his son, duke Albert, that on his accession to the crown of Germany, on the death of the latter, he displayed his resentment in more than one instance, not only refusing peremptorily to confirm their privileges, without vouchsafing to allege any reason for his refusal, but likewise setting over them two noblemen of the most infamous character for avarice and arrogance, whose administration became quite insupportable. On this, seeing that nothing less was in agitation than the total deprivation of their liberties, and the bringing them under the yoke of Austria, they united in a firm resolution to defend themselves to the last extremity. The tyranny of Grisler, the Austrian governor, hastened this resolution by his barbarously ordering William Tell, the celebrated Swiss patriot, to shoot an apple off his son's head at a considerable distance. Tell, having accomplished this without hurting his son, Grisler observed that he had another arrow concealed under his cloak, and asked him for what purpose that was. To which Tell boldly replied, 'To have shot you through the heart if I had had the misfortune to have killed my son.' On this the enraged governor ordered Tell to be hanged; but his fellow citizens flew to arms, attacked and vanquished Grisler, who was shot to death by William Tell, and instantly formed an association for their independence. This memorable event happened on the 7th of

November, 1307. See TELL. Arnold Melchthal of Unterwalden was the first who raised the standard of liberty. The citizens chose for commanders three gentlemen of approved courage and abilities; namely, Werner, or Gerhard Stauffach, of Schwitz, Walthur Furst of Uri, and Arnold Melchthal above-mentioned, who secretly agreed together that, on the first day of January, 1308, they should surprise and demolish the castles in which the imperial governors resided. This resolution being effected, these three places joined again in a league for ten years, which gave birth to the Helvetic confederacy. Schwitz being the most powerful of the three confederate places, and the first meeting of the confederates being held at Brunnen in its territories, as also the first league concluded there, and after that the first battle, by the success of which the liberty of the confederates was retrieved, being fought within its jurisdiction, its name was given to the general confederacy. The emperor Albert, thinking that this was the season for totally reducing these three places by force of arms, hastened to Baden to begin the preparations, but being, on his return, murdered by his brother's son, John of Habsburg, the design was dropped; till, not long after, the house of Austria invented another pretence for falling on the United Cantons. For these and other parts of Switzerland adhering to the emperor Louis of Bavaria, his competitor, Frederick of Austria, was so extremely irritated that the Switzers having, during their contests with the abbey of Einsidlen, made some of its monks prisoners, put them under the ban, to which the bishop of Constance added excommunication. The former was taken off again by the emperor Louis, and the latter by the archbishop of Mentz. Leopold, duke of Austria, by virtue also of a commission from his brother Frederick, above-mentioned, in 1315 attacked the confederates with a powerful army, but was defeated by them at Morgarten. Hereupon, on the 8th of December, 1315, they entered into a perpetual alliance, which proved the origin of the late Helvetic confederacy. In 1332 Lucern acceded to it; in 1351 Zurich and Glarus; and, in 1352, their number was increased by the accession of Zug and Berne.

For the space of 125 years this confederacy was composed only of the above eight territories or cantons, on which account they are called the Old Cantons. In 1481 Friburg and Soleure, and in 1501 Basil and Schaffhausen, were admitted into the confederacy; and in 1513 Appenzell also acceded to it. These thirteen towns and counties, which properly constituted the Helvetic republic, were united by a reciprocal convention, which, though not in all places the same, and the unions of the eight old and five later cantons differing in certain respects, yet in the principal points nearly agreed; the first and chief articles relating to the succors, assistance, and protection, to be given to any one of them in case of any unjust violence, and determining in what manner and by whom the reasons for any military enterprise should be discussed; as also how and where such succor should be given, and stating both the expenses of the war and the distribution of any acquisitions. The second

article regulated their procedure in accommodating any differences which might arise between two or more towns or cantons, &c. In some leagues, and particularly in those of the old towns, it was permitted to enter into any other connexions at pleasure, provided such connexions did not affect the original confederacy; but in the conventions with the later towns and cantons it was expressly stipulated that they should not contract any engagements without the privity, advice, and consent, of the old ones. The federal union, however, extended no farther than to the succors stipulated in the leagues, and other cases set forth in the same; in all other incidental affairs relative to the confederacy, the majority of votes was not obligatory to the whole body; particularly with respect to the making of alliances with foreign powers, wherein every town and canton was at liberty to act as a contracting party or not, and that even though such alliance should have been approved of by all the other towns and cantons. Thus the whole Helvetic body consisted properly of thirteen distinct republics or free states, united by oath for their mutual security and maintenance. It had for some centuries before the French revolution supported itself in an absolute freedom and independency, enjoyed all the privileges of majesty, made wars, concluded treaties, received and sent envoys from and to the several European powers, entered into alliances with them, given what form they thought proper to their constitution, enacted laws and ordinances both in temporal and spiritual affairs, and exercised all the various prerogatives of sovereignty. Accordingly, at the peace of Westphalia in 1648, it was acknowledged to be a free state even by the emperor and empire.

This brave nation continued to enjoy their freedom and independence under their respective various constitutions with little interruption, except what took place in their internal governments by occasional alterations, from 1648 till the commencement of the French revolution in 1789. But soon after that great event, which more or less convulsed all the states of Europe, the rage for innovation, and the hopes of establishing a perfect liberty and equality, reached the Swiss Cantons; and the democratic party not only attempted to overturn the old aristocratic governments, but even to new model those democratic cantons, the governments of which by universal suffrage, and other established privileges, appeared to be as perfectly free as they could be rendered by any change. At last, on the 22nd of March, 1798, they were revolutionised upon the plan of the French republic, under a directory and two councils. See HELVETIC REPUBLIC. After this the whole country was repeatedly overrun, and successive changes made in its government, by the different belligerent powers; while the inhabitants, notwithstanding the natural strength of their situation, were subjected to all the horrors of war.

One benefit however, was derived from these changes. An uniform mode of keeping accounts was adopted, viz. in franken or francs of ten batzen; each batze being divided into ten rappen. The franc is equal to one franc and a half of the

money of France. The money now coined consisted of gold pieces of thirty-two and sixteen francs, silver pieces of forty and twenty batzen, or four and two francs, and base silver pieces of ten and five batzen.

The Swiss are a brave, honest, hospitable, hardy, people; very true to their engagements, friendly, and humane. In short there is not a people in Europe whose national character stands higher. In their persons they are generally tall, robust, and well made; but their complexions are none of the best, and those that live in the neighbourhood of the mountains are subject to wens. The women are generally handsome and well-shaped, sensible and modest, yet frank, easy, and agreeable in conversation. Few of the peasants are miserably poor; many of them are rich, especially in the Protestant cantons, and that of Berne in particular.

Before the time of the French Revolution, the form of government was in some monarchical, in others aristocratical, and in others democratical. Their sovereigns were the princes of the empire, such as the bishop of Basil, and the abbot of St. Gall. The aristocratical governments were the cantons of Zurich, Basil, and Schaffhausen, with some incorporate places, as the towns of St. Gall, Muhlhauser, and Biel, the cantons of Berne, Lucerne, Friburg, and Soleure, over which were appointed Schultherszen or justiciaries, and Neufchatel, and Geneva. The democratical form of government prevailed in the six cantons of Uri, Schwitz, Unterwalden, Zug, Glaris, and Appenzell, which were under the direction of Landammans; as also, though with some variation, in the Grisons and the Valais, but in all every male of the age of sixteen, whether master or servant, had a vote in the enacting of laws, and electing of magistrates. The general annual diets were held at Baden or Frauenfeldt, extraordinary diets at Altorf. Lucerne took the lead of the Roman Catholic cantons, but Zurich, though less powerful than Berne, took the precedence of the whole. With respect to their military establishments the only regular forces here were those of the garrisons of Zurich, Berne, Basil, Geneva, and Arburg; but every burgher, peasant, and subject, was diligently to exercise himself in the use of arms, to appear on the stated days for shooting at a mark, to furnish himself with proper clothing, accoutrements, powder, and ball, to be always ready for the defence of his country, and punctually to comply with every article of war. Switzerland was, and probably still is, well provided with arsenals, particularly at Berne; but the only fortified places in it are Soleure, Zurich, Berne, Basil, and Arburg. The Switzers engaged in the service of foreign princes and states either merely as guards, or as marching regiments; in the latter case the government permitted the enlisting volunteers, though only in such states as they were in alliance or had made a previous agreement with: and no subject was to be forced into foreign service, nor even to be enlisted without the concurrence of the magistracy. All the advantages arising to the regencies from these levies, were usually only an annual subsidy paid by the state in whose favor the

levies were thus granted; and perhaps a promise of reciprocal aid when necessary. The public benefit, however, attending this custom was that these men, returning home after a long service abroad, were a great improvement to the standing militia of their country. The confederates of the Swiss cantons were the abbot of St. Gall and the Valais; the Grisons, towns of Geneva, St. Gall, Bienne, Muhlhausen, and Neufchatel. The independent states under the protection of the states or the allies were Gerisau Engelberg, and Kapperschweil, Roman Catholics; and Haldenstein, Protestants. The subjects were Baden, Morat, Granson, Echalen, Orbe, Schwarzenburg, Werdenberg, and Bienne, Protestants; the free bailiwics Utnach Gaster, the Italian bailiwics, Roman Catholics; and the Thurgau, Rheintal, Surgans, and Tockenburg, mixed. But great changes have taken place in the constitution and government of this country during the late revolutionary war.

At last, in the spring of 1814, the allied armies approached the Swiss frontier, and entered it with an overpowering force, refusing to acknowledge the neutrality, but promising the future independence of Switzerland. They proved faithful to this engagement. The number of cantons, increased by the French to nineteen, was now carried, by the addition of the Valais, Geneva, and Neufchatel, to twenty-two, the integrity and independence of which were recognised, as we have seen, by the congress of Vienna. Austria, however, reserved to herself the Valtelline, a mountainous district in the south-east, and formerly a dependency of the Grisons.

SWITZERLAND, a county of Indiana, United States, bounded west by Jefferson, south by the Ohio River, north in part by Indian lands, and east by Dearborn county. Its surface is, in some places, broken by the Ohio and Silver Creek hills. It is watered by Venoge and Plum creeks, and several small streams, some running into the Ohio, and others into White River. Vevay is the chief town.

SWOBBER, *n. s.* See SWABBER. A sweeper of the deck.

Cubbed in a cabin, on a mattress laid,
On a brown george with lousy swobbers fed.

Dryden.

The clergyman used to play at whist and swobbers: playing now and then a sober game at whist for pastime, it might be pardoned; but he could not digest those wicked swobbers.

Swift.

SWOLLEN, } The *part. pass.* of SWELL,
SWOLN. } which see.

Unto his aid she hastily did draw
Her dreadful beast, who, *swoln* with blood of late,
Came ramping forth with proud presumptuous gait.

Spenser.

When thus the gathered storms of wretched love
In my *swoln* bosom with long war had strove,
At length they broke their bounds: at length their force

Bore down whatever met its stronger course;
Laid all the civil bonds of manhood waste,
And scattered ruin as the torrent past.

Prior.

Whereas at first we had only three of these principles, their number is already *swoln* to five.

Baker on Learning.

SWOON, *v. n. & n. s.* Saxon *aprunan*. To suffer a suspension of thought and sensation; faint: the fit of fainting.

So play the foolish thongs with one that swoons;
Come all to help him, and so stop the air
By which he should revive.

Shakspeare.

We see the great and sudden effect of smells in fetching men again, when they swoon.

Bacon.

The most in years swooned first away for pain;
Then, scarce recovered, spoke.

Dryden.

There appeared such an ecstasy in his action, that he seemed ready to swoon away in the surprize of joy.

Tatler.

The woman finds it all a trick,
That he could swoon when she was sick;
And knows that in that grief he reckoned
On black-eyed Susan for his second.

Prior.

SWOOP, *v. a. & n. s.* Saxon *ƿƿipan*; Goth. *swepa*. To seize by falling at once as a hawk upon his prey: the act of so doing.

All my pretty ones?

Did you say all? What all? O hellkite! all?

What, all my pretty chickens and their dam,

At one fell swoop?

Shakspeare. Macbeth.

The nine-stoned trophy thus whilst she doth entertain,

Proud Tamer swoops along with such a lusty train,
As fits so brave a flood.

Drayton.

A fowl in Madagascar, called a ruck, the feathers of whose wings are twelve paces, can with as much ease swoop up an elephant as our kites do a mouse.

Wilkins.

The physician looks with another eye on the medicinal herb, than the grazing ox, which swoops it in with the common grass.

Glanville's Scepis.

This mouldering piecemeal in your hands did fall,
And now at last you came to swoop it all.

Dryden.

The eagle fell into the fox's quarters, and carried away a whole litter of cubs at a swoop.

L'Estrange.

SWOP, *v. a.* Of uncertain derivation.—Johnson. Mr. Thomson says, ingeniously, of Teut. *wo*, two, and *happen*, to acquire or gain. To change; to exchange one thing for another. A low word.

When I drove a thrust home, he put it by,
And cried, as in derision, Spare the stripling;
Oh that insulting word! I would have scopped
Youth for old age, and all my life behind,
To have been then a momentary man.

Dryden's Cleomenes.

SWORD, *n. s.* } Sax. *ƿƿeord*; Belg. *sweerd*;
SWORD'ED *adj.* } Teut. *schwerd*; Goth. *siord*.
SWORD'ER, *n. s.* } A weapon used in cutting
SWORD'FISH, } or thrusting: hence destruction
SWORD'KNOT, } by war; the punishment
SWORD'LAW, } or authority of justice:
SWORD'MAN, } sword is girt with a sword:
SWORD'PLAYER. } a swordsman, a cut-throat; a soldier: swordfish, a fish with a long bone projecting from its head: swordknot, the ribbon tied on the hilt of a sword: swordlaw is violence: swordman is also a soldier; one dextrous with the sword: swordplayer, a fencer; gladiator; a public prizefighter with the sword.

Each man took his sword, and slew all the males.

Genesis.

The sword without, and terrour within.

Deut. xxxii. 25.

A swordfish small him from the rest did sunder,
That in his throat him pricking softly under,
His wide abyss him forced forth to spew.

Spenser.

Old unhappy traitor, the sword is out
That must destroy thee. *Shakespeare. King Lear.*

A Roman sworder and banditto slave
Murdered sweet Tully. *Id. Henry VI.*

Worthy fellows, and like to prove most sinewy
swordmen. *Id. All's Well that ends Well.*

At Lecca's house,
Among your swordmen, where so many associates
Both of thy mischief and thy madness met.

Ben Jonson.

These they called swordplayers, and this spectacle
a sword-fight. *Hakewill on Providence.*

Essex was made lieutenant-general of the army,
the darling of the swordmen. *Clarendon.*

But the sword

Of Michael from the armoury of God
Was given him tempered so, that neither keen
Nor solid might resist that edge: it met
The sword of Satan with steep force to smite
Descending, and in half cut sheer. *Milton.*

The sworded seraphim
Are seen in glittering ranks with wings displayed. *Id.*

So violence

Proceeded, and oppression, and swordlaw,
Through all the plain, and refuge none was found. *Id.*

This I, her sword-bearer, do carry,
For civil deed and military. *Hudibras.*

Justice to merit does weak aid afford,
She quits the balance and resigns the sword. *Dryden*

Our little fleet was now engaged so far,
That like the swordfish in the whale they fought;

The combat only seemed a civil war,
Till through their bowels we our passage wrought. *Id.*

Malpighi observed the middle of the optick nerve
of the sword-fish to be a large membrane, folded,
according to its length, in many doubles, like a fan.
Derham's Physico-Theology.

Wigs with wigs, swordknots with swordknots strive,
Beaus banish beaus, and coaches coaches drive. *Pope.*

A SWORD is an offensive weapon worn at the
side, and serving either to cut or stab. Its parts
are the handle, guard, and blade; to which may
be added the bow, scabbard, pummel, &c.

SWORD OF STATE, which is borne before the
king, lords, and governors of counties, cities,
or boroughs, &c. For or before the king it ought
to be carried upright; the hilt as low as the
bearer's waist, the blade up between his eyes.
For or before a duke the blade must decline
from the head, and be carried between the neck
and the right shoulder. For or before an earl
the blade is to be carried between the point of
the shoulder and the elbow; and for or before a
baron the blade is to be borne in the bend of the
arm. This ceremonial form no less denotes the
dignity of a governor than the coronet set on his
coat of arms.

SWORD FISH. See XIPHIAS.

SYB, *adj.* Properly sib. Sax. *rib.* Related
by blood. Obsolete. But the Scottish dialect
retains it.

If what my grandsire to me said be true,
Siker, I am very *syb* to you. *Spenser's Pastorals.*

SYBARIS, an ancient city of Italy, in Lucania,
at the mouth of the river on the bay of Tar-
rentum; founded by a colony of Achaëans. It
became very rich and powerful; and at one

period had the command of four adjacent nations,
of twenty-five towns, and an army of 300,000
men. The city walls were six miles and a half
in circumference, and the suburbs covered seven
miles of the banks of Crathis. It was five times
destroyed, but always rebuilt. It stood a long
and vigorous siege by the Crotonians, but at
last was reduced by the Pythagoreans, A. A. C.
508. A town was built on its site called Thu-
rium, A. A. C. 444.

SYBARITÆ, SYBARITES, the people of Sy-
baris, who were long celebrated for bravery and
skill in arts; but at last degenerated so much by
the increase of luxury that Sybarite became
synonymous with effeminate.

SYCAMINE, *n. s.* } Gr. *συκομορος*. A tree.
SYCAMORE. } See below. The syc-
amore of Scripture is not the same with ours.

If ye had faith as a grain of mustard-seed, ye
might say unto this sycamore tree, Be thou plucked
up, and it should obey you. *Luke xvii. 6.*

I was no prophet, but an herdman, and a gatherer
of sycamore fruit. *Amos vii. 14.*

Go to yonder sycamore tree, and hide your bottle
of drink under its hollow root. *Walton's Angler.*

Sycamores with eglantine were spread;
A hedge about the sides, a covering over head. *Dryden.*

Sycamore is our acer majus, one of the kinds of
maples: it is a quick grower. *Mortimer's Husbandry.*

SYCAMORE, in botany. See ACER.

SYCAMORE TREE OF SCRIPTURE. See FIGUS.

SYCIAR, a city of Samaria, anciently called
Shechem. See SAMARIA, and SHECHEM.

SYCOPHANT, *n. s.* Gr. *συκοφαντης*; Lat.
sycophanta. A talebearer; makebate; a malicious
parasite.

Accusing *sycophants*, of all men, did best sort to
his nature; but therefore not seeming *sycophants*, be-
cause of no evil they said, they could bring any new
or doubtful thing unto him, but such as already he
had been apt to determine; so as they came but as
proofs of his wisdom, fearful and more secure, while
the fear he had figured in his mind had any possibility
of event. *Sidney.*

Men know themselves void of those qualities which
the imput *sycophant*, at the same time, both as-
cribes to them, and in his sleeve laughs at them for
believing. *South.*

His *sycophanting* arts being detected, that game is
not to be played a second time; whereas a man of
clear reputation, though his barque be split, has
something left towards setting up again.

Government of the Tongue.

SYCOPHANT was an appellation given by the
ancient Athenians to those who informed of the
exportation of figs contrary to law; and hence
it is still used in general for all informers, para-
sites, flatterers, &c.

SYDENHAM (Floyer), M. A., a learned
English writer, born in 1710, and educated at
Wadham College, Oxford; where he took his
degree in 1734. He translated some parts of
Plato's writings, and published them between
1753 and 1767. He was known and esteemed
by many gentlemen eminent in literature; but
having, from that excess of modesty which too
often accompanies great merit and excessive sen-
sibility, concealed his distress, he was put in jail

for a small debt contracted for maintenance, and died without letting his friends know his wants. Of this melancholy event the rev. and ingenious David Williams speaks in the following indignant and affecting terms in his *Claims of Literature*, p. 93:—“During the summer of 1788 an event took place which tarnished the character of English opulence and humanity, and afflicted the votaries of learning. Floyer Sydenham, the well known translator of Plato, one of the most useful, if not one of the most competent Greek scholars of his age, a man revered for his knowledge, and beloved for the candor of his temper, and the gentleness of his manners, died in consequence of having been arrested and detained for a debt to a victualler, who had for some time furnished his frugal dinner. At the news of that event every friend of literature felt a mixture of sorrow and shame; and one of the members of a club at the Prince of Wales’ coffee house proposed, that it should adopt, as its object and purpose, some means to prevent similar afflictions, and to assist deserving authors and their families in distress.” This gave rise to the establishment of that excellent institution, the Literary Fund for the relief of Authors and their Families.

SYDENHAM (Thomas), M. D., an excellent English physician, was the son of William Sydenham, of Winford Eagle, in Dorsetshire, and was born there about 1624. He studied at Magdalen Hall, Oxford; but left that university when Oxford was garrisoned for king Charles I., and went to London: where, becoming acquainted with Dr. Thomas Cox, an eminent physician, that gentleman persuaded him to study physic; accordingly, after the garrison was delivered up to the parliament, he retired again to Magdalen Hall, entered on the study of medicine, and in 1648 was created M. B. Soon after he was made a fellow of All Souls College, and continued there several years: when, leaving the university, he settled at Westminster; became M. D. at Cambridge; grew famous for his practice; and was the chief physician in London from 1660 to 1670; when he became disabled by the gout. He died in 1689.

SYDENHAM (William), elder brother of the above, was for some time a gentleman commoner of Trinity College, Oxford. Entering into the army of the parliament, he acquitted himself so well that he rose to the highest offices. In 1649 he was appointed governor of the Isle of Wight, and vice admiral of that isle and of Hampshire. In 1653 he was chosen M. P. for Dorsetshire; in 1654 was appointed commissioner of the treasury, and a member of the privy council; and in 1658 was summoned to parliament by the protector, Richard Cromwell. What became of him after the Restoration we know not.

SYDEROPECILUS, in mineralogy, a stone mentioned by the ancients. It was found in Arabia, and obtained this name from its being spotted with a ferruginous color. It might possibly be a granite with spots of this peculiar color.

SYDERVELT, a town of Holland, in the department of the Rhine, and late province of Guelderland; six miles west of Culemburg.

SYDLING, a town of England, in Dorset-

shire; called also St. Nicholas; with a fair December 6th.

SYDNEY, a thriving town of New Holland, and the capital of the British settlements in New South Wales. It is about seven miles from the mouth of Port Jackson, in a cove to which it gives name, and stands principally on two hilly necks of land, with a proportion of flat ground intervening. These together form one of the finest natural basins of water that can be imagined, and for safety and convenience rival the finest works of art. It is perfectly secured against any wind, and ships of any dimensions lie there. The western side of the town extends to the water’s edge, and occupies, with a small exception round Dawe’s battery, the whole of the neck of land which separates Sydney Cove from Lane Cove. On the eastern neck of land, the extension of the town has been stopped by the government-house, and the adjoining domain, which occupies the whole of Bennilong’s point.

Until the administration of governor Macquarrie, little or no attention had been paid to the laying out of the streets, and each proprietor was left to build as caprice inclined him. He, however, succeeded in establishing a perfect regularity in most of the streets, and, in all future additions that may be made to it, the proprietors of leases will not be allowed to deviate from the lines marked out by the surveyor-general. Here is a very good market, established by this governor in 1813, and very well supplied with grain, vegetables, poultry, butter, eggs, and fruit. It is held three times a week; viz. on Mondays, Wednesdays, and Fridays, in a large oblong enclosure. The vender pays a small duty to the clerk of the market. Here is also the New South Wales bank.

Two excellent public schools have been founded at Sydney. One is a day school for boys, and of course only intended to impart gratuitous instruction:—the other is designed both for the education and support of poor and helpless female orphans. Besides these two public schools in the town of Sydney, which together contained, by late accounts, 224 children, there are establishments for the gratuitous diffusion of education in every populous district throughout the colony: the masters being allowed stipulated salaries from the orphan fund. Formerly particular duties, those on coals and timber, which still go by the name of ‘the orphan dues,’ were allotted for the support of these schools; but they were found to be insufficient, and afterwards one-fourth, and more recently one-eighth, of the whole revenue of the colony was appropriated to this purpose. Independent of these laudable institutions, supported at the expense of the government, there are various private ones intended for the dissemination of religious knowledge. One is termed the Auxiliary Bible Society of New South Wales, and its object is to co-operate with the British and Foreign Bible Society, and to distribute the holy Scriptures either at prime cost, or gratis, to deserving applicants. Another is the New South Wales Sunday School Institution. There are also in this town and other parts of the colony, several good private semi-

aries for the board and education of the children of opulent parents.

The harbour of Port Jackson is considered equal to any in the world, and would contain the shipping of all countries. It is navigable for vessels of any burden for about seven miles above the town, i. e. about fifteen from the entrance, and possesses the best anchorage all the way. Value of land in Sydney town is daily increasing; rents are in consequence high; and Mr. Wentworth, in his statistical account of the British settlements in this quarter, mentions, that it is very far from a commodious house that can be had for £100 a year unfurnished. Population 7000. Long. 151° 25' E., lat. 33° 15' S.

SYDNEY, a river in the interior of New Holland, seen by Mr. Oxley in his second expedition. Its course was northward, and the part of it seen crossed 31° S. lat., long. 151° 15' E.

SYDNEY BAY, a bay on the south coast of Norfolk Island, in the South Pacific. Long. 168° 2' E., lat. 29° 5' N.

SYENE, an ancient city of Egypt, situated, according to Mr. Bruce, in lat. 24° 0' 45" N., although Pliny and Strabo both say that it lay directly under the tropic of Cancer. Syene is remarkable for being the place where the first attempt was made to measure the circumference of the earth, by Eratosthenes, whom Ptolemy Eurgetes had invited from Athens to Alexandria. It is now called Assouan. Here is still a small temple, supposed by some to be the ancient observatory. Mr. Hamilton cleared it till he reached the pavement, but he was interrupted before he dug down to the spot where the ancient well might have been expected. There are also the remains of a Roman bridge, and a handsome stone quay. But the principal ruins of Syene are those of the Saracen town, including the city wall, built of unburnt bricks, and flanked with square towers. Many large houses are still in a state of extraordinary preservation, as well as mosques, with lofty minarets, still entire. Although Syene is considered as a military station, yet the Aga is not provided with any force, and the castle is of no strength. In the Nile, opposite to Syene, is ELEPHANTINA, which see.

SYLAH, a large fortified town of Gujrat, district of Chawalara, Hindostan. The south of this town marks the boundary of Cottiwar, and here Gujrat Peninsula may be considered as terminating. This place is larger than Wankaneer, but not so well fortified. It belongs to a Rajpoot chieftain, but, like all others in this neighbourhood, pays a tribute to the Guicowar. A very large sheet of water covers the south face of the town. (Macmurdo, &c.)

SYLBURGIUS (Frederick), a learned German, born at Marpurz in Hesse, in 1546. He taught Latin, Greek, and French for some time at Licha; but afterwards applied himself solely to the revising and correcting of ancient authors, particularly the Greek classics, for the presses of Wechel and Commelin. He also greatly assisted the celebrated Henry Stephens in compiling his *Thesaurus Græcæ Linguae*. See STEPHENS. He likewise published a Greek Grammar, which was much esteemed. For these services he had a salary from the university of Marpurz. He died in 1596.

SYLEUM, an ancient town of Pamphylia.

SYLLA (Lucius Cornelius) was descended from the illustrious family of the Cornelii, but from a branch quite distinct from that of the Scipios. His debauched behaviour in his younger years did not correspond with his excellent education. Nicopolis, a rich courtesan, left him heir to her great estate. He learned the art of war under Marius, whom he attended to Numidia as questor; and soon became the most skilful soldier in the army, while by his obliging behaviour he gained the esteem of all. His courage and dexterity contributed to the success of the war; and his eloquence persuaded Bocchus to deliver up Jugurtha. He served afterwards in the social war, and as a reward he was raised to the prætorship, next elected consul, and soon after declared general of the army against Mithridates VII. king of Pontus. Marius was exasperated that the management of this war was not committed to him. The people were persuaded, by his intrigues, to reverse the decree, and substitute him in place of Sylla. Upon this he sent down officers to take the command of the army; but Sylla by this time had gained over the soldiers, who, instead of obeying the decree of the people, slew Marius's officers, and intreated Sylla to lead them instantly to Rome. Accordingly he entered the city sword in hand, slew Sulpicius the consul, obliged Marius to flee, new-modelled the laws, and afterwards marched into the east, and immediately laid siege to Athens; for that city, together with the rest of Greece, had fallen into the power of Mithridates. He wrote to the Amphycions, who were assembled at Delphi, to send him all the gold in the temple of Apollo, promising to restore it at the end of the war; and when he received it said that he now was sure of victory, since the gods themselves furnished him with money. Athens was at last taken by assault, and Sylla was upon the point of destroying it, when he recollected its ancient glory, and spared, as he said, the living for the sake of the dead. After burning the Piræus he gained two decisive victories over the generals of Mithridates. In the second battle, fought at Orchomenus, he was almost defeated; his troops began to flee, when, leaping from his horse, he snatched up a standard, and crying out, 'I will die here gloriously; and soldiers, when you are asked where you abandoned your general, answer, At Orchomenus.' This reproach recalled the courage of the Romans; they followed him and gained a complete victory. Mithridates then sued for peace. Mean time Cinna had declared against Sylla in Italy; and Marius returning from banishment had taken the most severe vengeance on all his enemies. Sylla was declared a traitor; his laws reversed, his friends were murdered, and the government new-modelled. These news induced Sylla to conclude a treaty with Mithridates, and march directly to Rome. His approach terrified the Romans. Marius and Cinna were both dead; but the consuls made vigorous preparations to oppose him. A civil war was begun, but Sylla in the end subdued all his enemies, and entirely ruined the Marian faction. He entered Rome at the head of his victorious army, and assumed the title of Felix

Happy. The remainder of his life was stained with the most abominable cruelties. He ordered 8000 wretches, who had thrown themselves upon his clemency, to be butchered in the Campus Martius. To carry on these cruelties with the appearance of justice, he commanded the people to elect him dictator. He kept this office above two years; and then, to the amazement of all, laid it down, and offered to stand his trial before the people. Soon afterwards he retired into the country, and plunged into every kind of debauchery. He died of the lousy disease, in the sixtieth year of his age. His person was elegant, his air noble, and his manners easy. He was eloquent, liberal, crafty, insinuating; and a profound master of dissimulation, by which he concealed a hideous train of vices. This Nero of the republic did one essential service to science by recovering the works of Aristotle at the taking of Athens.

SYLLABLE, *n. s. & v. a.* Fr. *syllabe*; Gr. *σλλαβη*. As much of a word as is uttered by the help of one vowel, or one articulation: to utter; pronounce.

Abraham, Job, and the rest that lived before any syllable of the law of God was written, did they not sin as much as we do in every action not commanded?

Hooker.

I heard

Each syllable that breath made up between them.

Shakspeare.

To-morrow, and to-morrow, and to-morrow,

Creeps in this petty pace from day to day;

To the last syllable of recorded time;

And all our yesterdays have lighted fools

The way to dusty death.

Id. Macbeth.

Airy tongues that syllable men's names

On sands, and shores, and desert wildernesses.

Milton.

There is that property in all letters of aptness to be conjoined in syllables and words, through the voluble motions of the organs from one stop or figure to another, that they modify and discriminate the voice without appearing to discontinue it.

Holder's Elements of Speech.

He hath told so many melancholy stories, without one syllable of truth, that he hath blunted the edge of my fears.

Swift.

SYLLABUB, *n. s.* Rightly **SILLABUB**, which see. Milk and acids.

No syllabubs made at the milking pail,
But what are composed of a pot of good ale.

Beaumont.

Two lines would express all they say in two pages:
'tis nothing but whipt syllabub and froth, without solidity.

Felton.

A SYLLABUB is a kind of compound drink, most usual in summer; ordinarily made of white wine and sugar, into which is squirted new milk with a syringe or wooden cow. Sometimes it is made of canary, in which case the sugar is spared, and a little lemon and nutmeg are added in lieu of it. To prepare it the best way, the wine and other ingredients, except the milk, are to be mixed over night, and the milk or cream added in the morning. The proportion is, a pint of wine to three of milk.

SYLLABUB WHIPT. To half a pint of white wine or rhenish is put a pint of cream, with the whites of three eggs. This they season with

sugar and beat with birchen rods, or work with a syringe. The froth is taken off as it rises, and put into a pot; where, after standing to settle two or three hours, it is fit to eat.

SYLLABUS, in literature, denotes a table of contents, or an index to the chief heads of a book.

SYLLEPSIS (*συλληψις*, Gr.), in grammar, a figure in which two nominative cases of the singular number are joined to a plural verb.

SYLLOGISM, *n. s.* Fr. *syllogisme*; Gr. *συλλογισμὸς*. An argument composed of three propositions: as, 'every man thinks; Peter is a man; therefore Peter thinks:' the derivatives all strictly corresponding.

Though we suppose subject and predicate, and copula, and propositions and syllogistical connexions in their reasoning, there is no such matter; but the entire business is at the same moment present with them, without deducing one thing from another.

Hale's Origin of Mankind.

A piece of rhetorick is a sufficient argument of logick, an apologue of Æsop beyond a syllogism-in-Barbara.

Browne.

A man knows first, and then he is able to prove syllogistically; so that syllogism comes after knowledge, when a man has no need of it.

Locke.

What a miraculous thing should we count it, if the flint and the steel, instead of a few sparks, should chance to knock out definitions and syllogisms!

Bentley.

Though the terms of propositions may be complex, yet, where the composition of the whole argument is thus plain, simple, and regular, it is properly called a simple syllogism, since the complexion does not belong to the syllogistical form of it.

Watts's Logick.

Men have endeavoured to transform logic into a kind of mechanism, and to teach boys to syllogize, or frame arguments and refute them, without real knowledge.

Watts.

Logic is, in effect, an art of syllogizing.

Baker.

A SYLLOGISM, in logic, consists of three propositions; the first two called premises; the last the conclusion. See LOGIC.

SYLOES, a promontory of Africa.

SYLPH, in modern mythology and dæmonology, an ideal being, somewhat analogous to the fairy of the British (see FAIRY); supposed to attend with anxious care about all the minutiae and paraphernalia of a fine lady.—Pope's Rape.

SYLVA. See PANCARPUS.

SYLVAN, *adj. & n. s.* Fr. *sylvain*. Woody; shady; relating to woods: a wood-god; a rustic.

Cedar and pine, and fir, and branching palm,

A sylvan scene! and, as the ranks ascend,

Shade above shade, a woody theatre

Of stateliest view.

Milton's Paradise Lost.

Eternal greens the mossy margin grace,

Watched by the sylvan genius of the place.

Her private orchards, walled on every side,

To lawless sylvans all access denied.

Id.

SYLVANUS, a brave warrior among the Franks, under the emperor Constantius, who being, by the most deliberate villany and forgery of Dynames, compelled to declare himself emperor, was afterwards, when his innocence was discovered, murdered by Ursicinus, another traitor. See CONSTANTINOPLE.

SYLVESTER (Joshua), born in 1563. He translated the works of Du Bartas; some pieces of Fracastorius from the Latin; and the Quatrains of Pibrac, with some other tracts from the French. He died in Holland, in 1618.

SYLVIA, or *Iliu*, or *Rhea Sylvia*, the mother of Romulus. See **RHEA** and **ROME**.

SYLVIA, in ornithology, a modern genus of birds, belonging to the order of passerres, formed by Dr. Latham, by limiting the motacilla to the wagtail, and arranging the other species formerly classed under that genus under the sylvia. See **ORNITHOLOGY**. The motacilla he thus describes:—The beak is subulated, slender, and somewhat indented at the point. The tongue seems torn at the end, and the tail is long. He thus characterises the sylvia:—The beak is subulated, straight, and small; the mandibles are nearly equal. The nostrils are obovate, and a little depressed. The exterior toe is joined at the under part to the base of the middle one. The tongue is cloven, and the tail is small. He makes thirteen species of the motacilla, and 174 species of the sylvia. See **MOTACILLA**.

SYLVIVS (*Aeneas*), I. and II. kings of Alba, the son and grandson of *Aeneas* the Trojan, by *Lavinia*. See **ROME**.

SYLVIVS (*Aeneas*). See **PIUS II.**

SYLVIVS (James), or James Du Bois, a celebrated French anatomist and physician, the son of Nicholas Du Bois, a camblet weaver, born at Amiens, in Picardy, in 1478. He acquired a great knowledge of Greek and Latin, and some Hebrew, under his elder brother Francis Sylvius, or Du Bois, who was principal of the College of Tournay, at Paris, and a great promoter of learning. James wrote several works on anatomy, medicine, and pharmacy, which have been often printed, though he was much opposed by his contemporaries. He defended Galen against Vesalius. See **ANATOMY**, Index. He was also a good mathematician, and invented several useful machines. His great vice was avarice, which prevented him from taking the degree of M. D., though he went to Montpellier in 1520 on purpose; but he was reconciled to his brethren and admitted M. B. in June 1531. He read lectures on Hippocrates and Galen, which spread his fame far and wide. In 1535 he was appointed a professor in the college of Triquet, and in 1548 professor of physic in the Royal College at Paris; which office he retained till his death, in 1555. He was never married.

SYMA, or **SYME**, a town of Asia.—Lempr.

SYMBOL, *n. s.* } Fr. *symbole*; Gr. }
SYMBOLICAL, *adj.* } *σύμβολον*; Lat. *sym-* }
SYMBOLICALLY, *adv.* } *bolum*. An abstract; }
SYMBOLIZATION, *n. s.* } compendium; com- }
SYMBOLIZE, *v. n. & v. a.* } prehensive form; }
 type; figurative representation: the adjective and adverb corresponding: to symbolize is to have some quality, or something in common with another, by symbolic representation: as a verb active, to make representative: symbolization corresponding.

The pleasing of colour *symbolizeth* with the pleasing of any single tone to the ear; but the pleasing of order doth *symbolize* with harmony. *Bacon*.

They both *symbolize* in this, that they love to loo' upon themselves through multiplying glasses.

Havel.

The sacrament is a representation of Christ's death, by such *symbolical* actions as himself appointed.

Taylor.

It *symbolically* teaches our duty, and promotes charity by a real signature and a sensible sermon.

Id.

Salt, as incorruptible, was the *symbol* of friendship; which, if it casually fell, was accounted ominous, and their amity of no duration.

Browne.

By this encroachment idolatry first crept in, men converting the *symbolical* use of idols into their proper worship, and receiving the representation of things unto them as the substance and thing itself.

Id.

Some *symbolize* the same from the mystery of its colors.

Id. Vulgar Errors.

The hieroglyphical *symbols* of Scripture, excellently intended in the species of things sacrificed in the dreams of Pharaoh, are oftentimes racked beyond their *symbolizations*.

Id.

I affectedly *symbolized* in careless mirth and freedom with the libertines, to circumvent libertinism.

More.

Aristotle and the schools have taught that air and water, being *symbolizing* elements, in the quality of moisture, are easily transmutable into one another.

Bacon.

The soul is such, that it strangely *symbolizes* with the thing it mightily desires.

South's Sermons.

Words are the signs and *symbols* of things; and as, in accounts, cyphers and figures pass for real sums, so words and names pass for things themselves.

Id.

The heathens made choice of these lights as apt *symbols* of eternity, because, contrary to all sublunary beings, though they seem to perish every night, they renew themselves every morning. *Addison on Metals.*

Beginning with the *symbol* of our faith, upon that the author of the gloss enquires into the nature of faith.

Baker.

A **SYMBOL** is a sign or representation of something moral, by the figures or properties of natural things. Hence symbols are of various kinds; as hieroglyphics, types, enigmas, parables, fables, &c.

SYMBOLUM, an ancient town of Macedonia, near Philippi; on the borders of Thrace.—Lempr.

SYME. See **SYMA**.

SYMI, or **SIMI**. See **SIMI**.

SYMMACHUS, a writer who flourished in the second century, and translated the Hebrew Bible into Greek. Only a few fragments of his work are extant.

SYMMACHUS, a senator and orator of Rome, who was consul A. D. 391. He wrote ten books of Epistles against the Christian religion; which are extant, and have been refuted by Ambrose, bishop of Milan, and Prudentius, the Christian poet. He was banished from Rome by Valentinian, but recalled and received into favor by Theodosius. Ammianus Marcellinus speaks of him as a man of great learning and modesty. Scioppius, Pareus, and other learned men, have written notes upon his epistles. The best editions are those of Geneva, 8vo., 1598; Paris, 4to., 1604; and Franckfort, 8vo., 1642.

SYMMETRY, *n. s.* } Fr. *symmetric*; Gr. }
SYMMETRIAN, *n. s.* } *συν* and *μετρον*. Adap- }
SYMMETRICAL, *adj.* } tation or agreement of }
SYMMETRIST, *n. s.* } parts: proportion; bal-

mony : a symmetrian or symmetrist is one who studies proportion : symmetrical, proportionate.

His face was a thought longer than the exact *symmetrians* would allow. *Sidney.*

She by whose lines proportion should be Examined, measure of all *symmetry* ; Whom had that ancient seen, who thought souls made

Of harmony, he would at next have said That harmony was she. *Donne.*

Some exact *symmetrists* have been blamed for being too true. *Wotton's Architecture.*

Symmetry, equality, and correspondence of parts, is the discernment of reason, not the object of sense. *More.*

Nor were they only animated by him, but their measure and *symmetry* were owing to him. *Dryden.*

SYMMETRY is the just proportion of the several parts of any thing, so as to compose a beautiful whole.

SYMMETRY, in painting. See PAINTING.

SYMMONS (Charles), D. D., a native of Cardigan, which his father had represented in three successive parliaments, was born in 1749, and received the rudiments of his education at Westminster school, whence he removed to Glasgow, and subsequently to Clare-hall, Cambridge. Having graduated in 1776 as bachelor of divinity, he obtained two years afterwards the rectory of Narberth, and in 1794 that of Lampteter in Pembrokeshire. This last piece of preferment he narrowly escaped losing, in consequence of a sermon preached by him at Cambridge, before the presentation was made out, the discourse containing some whiggish sentiments little congenial to those then in power. The same cause operated to throw difficulties in the way of his doctor's degree, and he therefore found it advisable to enter himself ad eundem at Jesus College, Oxford, in which university he proceeded D. D. in March. Dr. Symmons was a warm admirer of literature, and a zealous supporter of the Literary Fund. His own writings consist of Inez, a dramatic poem, 1797 ; a second entitled Constantia, 1800 ; an octavo volume of miscellaneous poetry, partly of his own composition and partly that of his daughter, 1813 ; a Rhymed translation of the *Æneid*, 1817 ; and a Life of Milton, prefixed to an edition of that author's prose works. After his decease, which took place at Bath in the spring of 1826, his friend, Mr. Whittingham, published a posthumous biographical sketch of Shakspeare of his writing.

SYMONDSBOROUGH, a remarkable large borough of Flintshire, near Wellington in Devonshire, in the northern extremity of Hemyock. The people have a notion that a king called Symon was buried here.

SYMPATHETIC INK. A good sympathetic ink has been made from a solution of a mixture of sulphate of copper and muriate of ammonia, which appears of a bright yellow when exposed to heat, but disappears with cold or moisture.

SYMPATHY, *n. s.* } Fr. *sympathie* ;
SYMPATHET'IC, or } Greek *συμπάθεια*.
SYMPATHET'ICAL, *adj.* } Fellowfeeling; mutual
SYMPATHET'ICALLY, *adv.* } sensibility; the
SYMPATHIZE, *v. n.* } quality of being af-

fected by the affection of another : the adjective, adverb, and verb neuter correspond.

You are not young ; no more am I : go to, then, there's *sympathy* : you are merry, so am I ; ha ! ha ! then there's more *sympathy* ; you love sack, and so do I ; would you desire better *sympathy* ?

Shakspeare. Merry Wives of Windsor.
They saw, but other sight instead, a crowd Of ugly serpents : horror on them fell, And horrid *sympathy*. *Milton.*

Or *sympathy*, or some connat'ral force, Powerful at greatest distance to unite, With secret amity, things of like kind, By secretest conveyance. *Id. Paradise Lost.*

The thing of courage, As roused with rage, with rage doth *sympathize*. *Milton.*

To confer at the distance of the Indies by *sympathetick* conveyances, may be as usual to future times as to us in a literary correspondence. *Glanville.*

Hereupon are grounded the gross mistakes in the cure of diseases, not only from *sympathetick* receipts, but amulets, charms, and all incantatory applications. *Browne.*

United by this *sympathetick* bond, You grow familiar, intimate, and fond. *Roscommon.*

Green is a pleasing color, from a blue and a yellow mixed together, and by consequence blue and yellow are two colours which *sympathize*. *Dryden.*

Can kindness to desert like your's be strange ? Kindness by secret *sympathy* is tied ; For noble souls in nature are allied. *Id.*

There are such associations made in the minds of most men ; and to this might be attributed most of the *sympathies* and antipathies observable in them. *Locke.*

There never was any heart truly great and generous, that was not also tender and compassionate : it is this noble quality that makes all men to be of one kind ; for every man would be a distinct species to himself, were there no *sympathy* among individuals. *South's Sermons.*

Their countrymen were particularly attentive to all their story, and *sympathized* with their heroes in all their adventures. *Addison's Spectator.*

To you our author makes her soft request, Who speak the kindest, and who write the best ; Your *sympathetick* hearts she hopes to move, From tender friendship and endearing love. *Prior.*

Though the greatness of their mind exempts them from fear, yet none condole and *sympathize* more heartily. *Collier.*

All the ideas of sensible qualities are not inherent in the inanimate bodies ; but are the effects of their motion upon our nerves, and *sympathetical* and vital passions produced within ourselves. *Beniley.*

SYMPATHY also signifies an agreement of affections and inclinations, or a conformity of natural qualities, humors, temperaments, which make two persons delighted and pleased with each other.

SYMPATHY may subsist either between different persons or bodies, or between different parts of the same body. It is either similar or dissimilar : similar, when the affection or action in the sympathiser is similar to the affection or action in the sympathant ; and dissimilar when those are different.—Sympathy, too, is often an imitative faculty, sometimes involuntary, frequently without consciousness : thus we yawn when we see others yawn, and are excited to laugh by the laughing of others. Sympathy, according to Dr. Jackson, relates to the operations of the affec-

tions of the mind, to the operations of the imagination, and to the affections of the external senses. 1. The affections of the mind produce in the body different sensations and impressions, and, as sympathies of consciousness, determine in general the spirits to those parts which are most apt to be affected. The affections of the mind of one person will often work upon the spirits of many. Thus whole companies are sometimes disposed to be sad and melancholy or merry and jovial, when any one present is much inclined to either of those states of mind. Those tender sympathetic affections which lay hold of the mind at the representation of theatrical performances originate from the same principle, while they are the surest test of just execution in the actor, and of the expressive language of the author. Indeed all stage effect depends on sympathy. 2. It is probable that a connexion between the affections and sensations of the female mind and uterus is very materially concerned in the process of generation, and probably can alone give efficacy to those actions and impressions subservient to conception through the sympathising affections of the mind. But this is a subject of which we as yet know little; though the facts are numerous and incontrovertible; but physiologists seem unwilling to admit of them, because they cannot account for them. See SURGERY. 3. As affecting the senses, sympathies have been compared to unisons of sound in music, which produce agreeable sympathetic feelings; and the reverse produces disagreeable feelings. 'All concords and discords of music are sympathies and antipathies of sound.' A disagreeable sound will often set the teeth on edge. The most agreeable as well as odious objects operate in a secondary way in producing those sympathetic impressions and actions which they commonly give rise to. An increased secretion of saliva often takes place at the sight of a favorite dish. Many have attempted to account for the remarkable sympathy which takes place between parts of the body seemingly unconnected with each other; but these attempts are merely conjectures.

SYMPHLEGMA (Gr. *συμπλεγμα*, an embracing, from *συν*, with, and *πλενω*, to fold or join), in painting and sculpture, a term used to denote a group of persons interlaced with each other. Thus we may, according to Winckelmann, call the children of Niobe a symphlegma. Pliny gives this name to two famous groups of wrestlers; the one of Cephessodorus, of which it was said that the hands of the figures appeared rather to be buried in flesh than in marble; and the other of Heliodorus, who represented the struggle of Pan and Olympus. But this appellation of symphlegma cannot be applied to two figures placed by each other's side, as Gort has imagined.

SYMPHONIA, in botany, a genus of plants, belonging to the class of monadelphia and order of pentandria.—There is one pistil: cor. globular, and the berry five-celled. There is only one species yet discovered, viz. *S. globolifera*.

SYMPHONY, *n. s.* } Fr. *symphonie*; Gr. **ΣΥΜΦΩΝΙΟΥΣ**, *adj.* } *συν* and *φωνη*. Concert or instruments; harmony of sounds: the adjective corresponding.

A learned searcher from Pythagoras's school, where it was a maxim that the images of all things are latent in numbers, determines the comeliest proportion between breadths and heights reducing symmetry to *symphony*, and the harmony of sound to a kind of harmony in sight. *Wotton.*

Up he rode,
Followed with acclamation and the sound
Symphonious of ten thousand harps, that tuneful
Angelick harmonies. *Milton.*

Speak ye who best can tell, ye sons of light,
Angels! for ye behold him, and with songs
And choral *symphonies*, day without night,
Circle his throne rejoicing. *Id. Paradise Lost.*

The trumpets sound,
And warlike *symphony* is heard around;
The marching troops through Athens take their way;
The great earl marshal orders their array. *Dryden.*

SYMPHONY, in music, denotes a consonance of several sounds agreeable to the ear, whether vocal or instrumental. See HARMONY.

SYMPHYSIS, *n. s.* Gr. *συν* and *φύω*. Defined below.

Symphysis, in its original signification, denotes a connascency, or growing together; and perhaps is meant of those bones which in young children are distinct, but after some years unite and consolidate into one bone. *Wiseman.*

SYMPHYSIS, in anatomy, one of the kinds of junctures or articulations of the bones. See ANATOMY.

SYMPHYTUM, comfrey, in botany, a genus of plants belonging to the class of pentandria, and order of monogynia; and in the natural system ranging under the forty-first order, *asperifolia*. The limb of the corolla is tubular and ventricose, and the throat is shut with awl-shaped rays. There are three species; of which *S. officinale* is a British plant. The stem is about two feet high, round, branched, green, and rough. The radical leaves are very large and rough; those on the stalks are decurrent and alternate. The flowers grow on loose spikes, and are either of a yellowish or purple color. It grows on the banks of rivers and flowers from May to October.

SYMPLEGADES, or *Cyaneæ*, two rugged islands at the entrance of the Euxine Sea; twenty stadia from the mouth of the Thracian Bosphorus: the one on the coast of Asia, and the other on that of Europe; separated by only twenty furlongs of water, which however foams and rages constantly, so as to render the passage very dangerous. They were first explored by the Argonauts. They were also called *Planeta*, or *Wanderers*, from a mistaken idea that they moved or floated.

SYMPLÖCE, *συμπλοκη*, in rhetoric, a figure, where the same word is repeated. See ORATORY.

SYMPLICOS, in botany, a genus of plants belonging to the class of polydelphia, and to the order of polyandria: and in the natural system ranging under those the order of which is doubtful. The calyx is quinquefid and interior: the corolla is pentapetalous: the stamina are attached to the tube of the corolla in a four-fold series. There are five species; viz. 1. *S. alstonia*; 2. *S. arcehea*; and, 3. *S. cisponina*; described by Mr. L'Héritier of the Academy of Sciences at

Paris. 4. *S. Martinicensis*, the only species described by Linnæus, is a native of Martinico. 5. *S. tinctoria*, a plant used by dyers, is also mentioned by L'Heritier.

SYMPOSIAC, *adj.* Fr. *symposiaque*; Gr. *συμμοσιακος*. Relating to merry makings, or a drinking party.

By desiring a secrecy to words spoke under the rose, we only mean in society and comotation, from the ancient custom of *symposiack* meetings to wear chaplets of roses about their heads. *Browne.*

In some of those *symposiack* disputations amongst my acquaintance, I affirmed that the dietetick part of medicine depended upon scientifick principles.

Arbuthnot.

SYMPOSIARCH, from *συμποσιον*, a banquet, and *αρχον*, governor, in antiquity, the director or manager of an entertainment. This office was sometimes performed by the person at whose charge the entertainment was provided; sometimes by another named by him; and at other times, especially in entertainments provided at the common expense, he was elected by lot, or by the suffrages of the guests.

SYMPTOM, *n. s.* } Fr. *symptome*;
SYMPTOMATIC, or } Greek *σύμπτωμα*.
SYMPTOMATICAL, *adj.* } Something that hap-
SYMPTOMATICALLY, *adv.* } pens concurrently
with something else: hence a sign or token: the adjective and adverb corresponding.

Symptomatical is often used to denote the difference between the primary and secondary causes in diseases; as a fever from pain is said to be *symptomatical*, because it arises from pain only; and therefore the ordinary means in fevers are not in such cases to be had recourse to, but to what will remove the pain; for, when that ceases, the fever will cease, without any direct means taken for that. *Quincy.*

The *symptoms*, as Dr. Sydenham remarks, which are commonly scorbutick, are often nothing but the principles or seeds of a growing, but unripe gout.

Blackmore.

By fomentation and a cataplasm the swelling was discussed; and the fever, then appearing but *symptomatical*, lessened as the heat and pain mitigated.

Wise man's Surgery.

The causes of a bubo are vicious humours abounding in the blood, or in the nerves, excreted sometimes critically, sometimes *symptomatically*.

Wise man's

Ten glorious campaigns are passed, and now, like the sick man, we are expiring with all sorts of good *symptoms*.

Swift.

SYMPTOM, in medicine, means any circumstance which indicates the existence, nature, or stage of a disease. Pain, weakness, drowsiness, convulsions, suppression of urine, difficulties of breathing and swallowing, coughs, distastes, nausea, thirsts, swoonings, faintings, looseness, costiveness, dryness and blackness of the tongue, are the principal symptoms of diseases. See **MEDICINE**.

SYMUS, a mountain of Armenia, from which the Araxes rises.

SYNERESIS, or *Crisis*, contraction, in grammar, a figure whereby two syllables are united in one; as *vemens*, for *vehemens*, *οφεις* for *οφιας*, *τυχος* for *τυχεος*, &c.

SYNAGOGUE, *n. s.* Fr. *synagogue*; Gr. *συναγωγη*. An assembly of the Jews to worship: a place for such worship.

As his custom was, he went into the *synagogue* on the sabbath.

Gospel.

Go, Tubal, and meet me at our *synagogue*.

Shakspeare.

SYNAGOGUE, among the Jews, was a place where people met to worship. Authors are not agreed about the time when the Jews first began to have synagogues: some will have them as old as the ceremonial law, and others fix their beginning to the times after the Babylonish captivity. They erected synagogues not only in towns and cities, but also in the country, especially near rivers, that they might have water for their purifications and ceremonious washings. No synagogue was built in any town, unless there were ten persons of leisure in it; but there might be many in one town, or in one quarter of a town, provided it was very populous. Jerusalem is said to have contained 480. The chief things belonging to a synagogue were, 1. The ark or chest, made after the model of the ark of the covenant, containing the Pentateuch. 2. The pulpit and desk in the middle of the synagogue, in which he that was to read or expound the law stood. 3. The seats or pews for the people. 4. The lamps to give light at evening service, and the feast of dedication. 5. Rooms or apartments for the utensils and alm-chests. The synagogue was governed by a council or assembly, over whom was a president, called the ruler of the synagogue. These are sometimes called chiefs of the Jews, the rulers, the priests or elders, the governors, the overseers, the fathers of the synagogue. Their business was to punish the disobedient by censures, excommunication, or penalties, such as fines and scourging; to take care of the alms, which are frequently called by the name of righteousness. The chief ruler, or one of the rulers, gave leave to have the law read and expounded, and appointed who should do it. In every synagogue there were several ministers who had different offices assigned to them. Service was performed three times a day, viz. in the morning, in the afternoon, and at night; at the time of morning sacrifice, evening sacrifice, and after the evening sacrifice on Mondays, Thursdays, and Saturdays, there was a more forcible obligation upon the people to attend, than upon the other days. There are synagogues at London, Amsterdam, Rotterdam, Avignon, Metz, &c.

SYNALEPHA, *n. s.* Greek *συναλοιφή*. A contraction, or excision of a syllable in Latin verse, as *ill' ego*.—Bailey.

Virgil, though smooth, is far from affecting it: he frequently uses *synalephas*, and concludes his sense in the middle of his verse. *Dryden.*

SYNALEPHIA, or **SYNALEPHA**, in grammar, or collisio, a contraction of syllables, performed principally by suppressing some vowel or diphthong at the end of a word, on account of another vowel or diphthong at the beginning of the next, as *ill' ego* for *ille ego*, &c.

Conticuer' omnes intentiqu' ora tenebant. *Virgil.*

SYNARTHROSIS, *n. s.* Gr. *συν* and *αρθρωσις*. A close conjunction of two bones.

There is a conspicuous motion where the conjunction is called *diarthrosis*, as in the elbow; an ob

scure one, where the conjunction is called *synarthrosis*, as in the joining of the carpus to the metacarpus.

Wiseman's Surgery.

SYNARTHROSIS. See ANATOMY, Index.

SYNCELLUS, an ancient Byzantine historian, of whom we have met with no memoir; which is the more surprising that his works are still extant, and were published at Paris in folio, in 1652.

SYNCELLUS, or **SINCELLUS**, an ancient officer in the family of the patriarchs, and other prelates of the eastern church. The word, in the corrupt Greek, *συγκηλλος*, signifies a person who lies in the chamber with another; a chamber-fellow or chum. The syncellus was an ecclesiastic, who lived with the patriarch of Constantinople, to be a witness of his conduct; whence it is that the syncellus was also called the patriarch's eye; because his business was to observe and watch. The other prelates had also their syncelli, who were clerks living in the house with them, and even lying in the same chamber, to be witnesses of the purity of their manners. Afterwards the office degenerated into a mere dignity; and there were made syncelli of churches. At last it became a title of honor, and was bestowed by the emperor on the prelates themselves; whom they called pontificales syncelli, and syncelli Augustales.

SYNCHONDROSIS, *n. s.* Greek *σύν* and *χόνδρος*.

Synchondrosis is an union by gristles of the sternon to the ribs. *Wiseman.*

SYN'CHRONISM, *n. s.* } Greek *σύν* and
SYNCHRONICAL, *adj.* } *χρόνος*. Concur-
SYN'CHRONOUS. } rence of events

happening at the same time: both the adjectives corresponding.

The coherence and *synchronism* of all the parts of the Mosaical chronology, after the Flood, bear a most regular testimony to the truth of his history.

Hale.

It is difficult to make out how the air is conveyed into the left ventricle of the heart, the systole and diastole of the heart and lungs being far from *synchronous*.

Boyle.

The variations of the gravity of the air keep both the solids and fluids in an oscillatory motion, *synchronous* and proportional to their changes.

Arbutnot on Air.

SYNCHYSIS, in Latin prosody, that confused and intricate order of the words, which is so frequently used by the best Latin poets, and is commonly called the artificial order: as *Saxa vocant Itali mediis quæ in fluctibus Aras*.—Virgil.

SYNCOPIATION, in music, denotes a striking or beating of time, whereby the distinction of the several times or parts of the measure is interrupted. However, it is more properly used for the connecting the last note of any measure or bar, with the first of the following measure, so as only to make one note of both. A *syncope* is sometimes also made in the middle of a measure. *Syncoption* is also used when a note of one part ends or terminates on the middle of a note of the other part. This is otherwise denominated *binding*. It is likewise used for a driving note; that is, when some shorter note at the beginning of a measure, or half measure, is

followed by two, three, or more longer notes before another short note occurs, equal to that which occasioned the driving, to make the number even, e. gr. when an odd crotchet comes before two or three minims, or an odd quaver before two, three, or more crotchets. In *syncoption* or driving notes, the hand or foot is taken up, or put down, while the note is sounding.

SYNCOPE, *n. s.* } Fr. *syncope*; Gr. *σνϕ*-
SYNCOPIST. } *σκοπή*. Fainting fit; contraction of a word; a contractor of words.

To outshine all the modern *syncopists*, and thoroughly content my English readers, I intend to publish a *Spectator* that shall not have a single vowel in it. *Spectator.*

The symptoms attending gunshot wounds are pain, fever, delirium, and *syncope*. *Wiseman.*

SYNCOPE, in grammar, an elision or retrenchment of a letter or syllable out of the middle of a word, as *caldus* for *calidus*.

SYNCOPE, in medicine, fainting; a deep and sudden swooning, wherein the patient continues without any sensible heat, motion, sense, or respiration, and is seized with a cold sweat over the whole body; all the parts, in the mean time, turning pale and cold, as if he were dead. See **MEDICINE**.

SYNDIC, in government and commerce, an officer in divers countries, entrusted with the affairs of a city or other community, who calls meetings, makes representations and solicitations to the ministry, magistracy, &c., according to the exigency of the case.

SYNDICATE, *v. n.* Fr. *syndiquer*; Gr. *σύν* and *δικη*. To judge; pass judgment on; censure. Not in use.

Aristotle undertook to censure and *syndicate* his master, and all law-makers before him. *Hakewill.*

SYNDROME, *n. s.* Gr. *σύνδρομή*. Concurrent action; concurrence.

All things being linked together by an uninterrupted chain of causes, every single motion owes a dependance on such a *syndrome* of prerequisite motors.

Glanville's Scepis.

SYNECDOCHE, *n. s.* } Fr. *synecdoche*;
SYNECDOCHICAL, *adj.* } Gr. *συνεκδοχή*. A figure by which part is taken for the whole, or the whole for part: the adjective corresponding.

Because they are instruments of grace in the hand of God, and by these his holy spirit changes our hearts; therefore the whole work is attributable to them by a *synecdoche*; that is, they do in this manner the work for which God ordained them.

Taylor's Worthy Communicant.

Should I, Lindamer, bring you into hospitals, and shew you there how many souls, narrowly lodged in *synecdochical* bodies, see their earthen cottages moulder away to dust, those miserable persons, by the loss of one limb after another, surviving but part of themselves, and living to see themselves dead and buried by piecemeal? *Boyle.*

SYNECOCHE. See **ORATORY**.

SYNECPHONESIS, in grammar, a coalition, whereby two syllables are pronounced as one; being much the same as *Synaloepha* and *Synæresis*.

SYNESIS, in Latin grammar, a figure whereby the construction of a sentence is regulated not by the words, but by the sense, as to gender

or number: as, in Livy, *Latium Capuaque agro multati*; instead of *Latini et Capuani*.

SYNESIUS, a celebrated father of the Christian church, who flourished under Theodosius II. He was born at Cyrene, in Africa, of noble parentage. In 410 he was appointed bishop of Ptolemais. His works consist of 155 Epistles, and some other curious tracts, written in very pure and elegant Greek. The best editions are those of Paris, in 8vo., 1605; folio, 1612, and 1633; and Amsterdam, 1749.

SYNEUROSI. See **ANATOMY**.

SYNGE (Edward), a late eminent prelate of Ireland, was the son of Dr. Edward Synge, bishop of Cork, and born April 6th, 1659, at Inishonane. He was educated at Cork; admitted commoner and A. B. at Christ Church, Oxford; and finished his studies at Dublin. He was made vicar at Christ Church, in Cork, and after other promotions rose to be bishop of Raphoe, in 1714; and at last, in 1716, archbishop of Tuam, being a zealous whig. He wrote and published many excellent tracts on divinity, in 4 vols. 12mo; and died at Tuam, in 1741.

SYNGENESIA, *συν* and *γενεσις*, congeneration. The nineteenth class in Linnæus's artificial system; comprehending those plants which have the antheræ united into a cylinder. The orders are six: 1. Polygamia æqualis. 2. Polygamia superflua. 3. Polygamia frustranea. 4. Polygamia necessaria. 5. Polygamia segregata. 6. Monogamia. The first five orders contain the compound flowers, and form a class truly natural. See **BOTANY**.

SYNGNATHUS, in ichthyology, pipe fish, according to Linnæus, a genus belonging to the class of amphibia, and order of nantes, but arranged by Gmelin more properly under the class of pisces, and order of branchiostegi. The head is small; the rostrum somewhat cylindrical, long, and turned up at the point, where the mouth is placed, which is covered with a lid or valve. The gills are covered in the same manner. The body is covered with a strong crust, and has no ventral fins. There were formerly enumerated eight species. Of these, three are found in the British seas, viz. No. 1, 3, and 5.

1. *S. acus*, the needle fish, or shorter pipe fish, is thicker than the barbarus (No. 3), yet it has been seen of the length of sixteen inches. The middle of the body in some is hexangular, in others heptangular. The mouth is formed like that of the barbarus, the irides are yellow; close behind the head are the pectoral fins, which are small and short. On the lower part of the back is one narrow fin; beyond the vent the tail commences, which is long and quadrangular. At the extremity is a fin round and radiated. The body is covered with a strong crust, elegantly divided into small compartments. The belly is white; the other parts are brown.

2. *S. æquoreus*.

3. *S. barbarus*, or longer pipe fish. One described by Sir Robert Sibbald was two feet in length; that examined by Mr. Pennant only sixteen inches. The nose was an inch long, compressed sidewise, and the end of the lower mandible turned up; the aperture of the mouth

was very small. The irides were red; behind each ear was a deep brown line. The body, in the thickest part, was equal to a swan's quill, hexangular from the end of the dorsal fin; thence to the tail quadrangular. The belly was slightly carinated, and marked along the middle with a dusky line. Under the tail, commencing at the anus, is a fulcus or groove, six inches and a half long, covered by two longitudinal valves, which conceal a multitude of young fish. On crushing this part, hundreds may be observed to crawl out.

4. *S. hippocampus*, the sea horse, which was classed by Artedi under the *Syngnathus*, is now, by later ichthyologists, arranged under *TRICHCUS*; which see.

5. *S. ophidion*, or little pipe fish, seldom exceeds five inches in length, is very slender, and tapers to a point. It wants both the pectoral and tail fins; is covered with a smooth skin, not with a crust. The nose is short, and turns a little up; the eyes are prominent. On the back is one narrow fin. This species is not viviparous: on the belly of the female is a long hollow, to which adhere the eggs in two or three rows. They are large, and not numerous. Serpent is used in several languages to express these fish: the French call one species *orueul*, from a sort of snake, like the blindworm; the Germans call it *meherchange*; and the Corinth the sea adder.

6. *S. Pelagicus*, 7. *S. tetragonus*, 8. *S. typhela*, and *S. æquoreus*, are all natives of foreign countries.

SYNNADA, or **SYNNAS**, an ancient town of Phrygia, famous for marble quarries.—Strab. 12, Claud.

SYNNEUROSI, *n. s.* Gr. *σύν* and *νεῦρος*.

Synneurosis is when the connexion is made by a ligament. Of this in symphysis we find instances, in the connexion of the ossa pubis together, especially in women, by a ligamentous substance. In articulation, it is either round, as that which unites the head of the os femoris to the coxa; or broad, as the tendon of the patella, which unites it to the os tibiae.

Wiseman's Surgery.

SYNOCHA, and **SYNOCHUS**, in medicine, species of continued fever. See **MEDICINE**.

SYNOD, *n. s.*

SYNO'DICAL, *adj.* } Fr. *synode*; Gr. *σύνδοδος*.
SYNO'DICALLY, *adv.* } An assembly called for consultation: it is used particularly of ecclesiastics. A provincial synod is commonly used, and a general council; conjunction of the heavenly bodies: the adjective and adverb follow both these senses.

The glorious gods sit in hourly *synod* about thy particular prosperity. *Shakspeare. Coriolanus.*

Since the mortal and intestine jars

'Twill thy seditious countrymen and us,

It hath in solemn *synod* been decreed

'T' admit no traffick to our adverse towns.

Shakspeare.

The opinion was not only condemned by the *synod*, but imputed to the emperor as extreme madness.

Bacon.

Howe'er love's native hours are set,

Whatever starry *synod* met,

'Tis in the mercy of her eye,

If poor love shall live or die.

Crashaw.

His royal majesty, according to these presbyterian rules, shall have no power to command his clergy to keep a national *synod*. *W'hu.*

The various dignity of their several churches, and of their many functions, rules, and orders in them, by reason of the frequency of their *synodical* and processional meetings, have necessarily raised many questions of place among them. *Selden.*

Flea-bitten *synod*, an assembly brewed
Of clerks and elders ana, like the rude
Chaos of presbytery, where laymen guide,
With the tame woolpack clergy by their side. *Cleveland.*

Let us call to *synod* all the best
Through heaven's wide bounds. *Milton.*

Their planetary motions and aspects
Of noxious efficacy, and when to join
In *synod* unbeneign. *Id.*

It shall be needful for those churches *synodically*
to determine something in those points. *Saunders.*

The diurnal and annual revolutions of the sun,
to us are the measures of day and year; and the
synodick revolution of the moon measures the month. *Holder.*

St. Athanasius writes a *synodical* epistle to those
of Antioch, to compose the differences among them
upon the ordination of Paulinus. *Stillingfleet.*

The second council of Nice, he saith, I most irreverently call that wise *synod*; upon which he falls into a very tragical exclamation, that I should dare to reflect so much dishonour on a council. *Id.*

As the planets and stars have, according to astrologers, in their great *synods*, or conjunctions, much more powerful influences on the air than are ascribed to one or two of them out of that aspect; so divers particulars which, whilst they lay scattered among the writings of several authors, were inconsiderable, when they come to be laid together, may oftentimes prove highly useful to physiology in their conjunctions. *Boyle.*

Parent of gods and men, propitious Jove!
And you bright *synod* of the powers above,
On this my son your gracious gifts bestow. *Dryden.*

The moon makes its *synodical* motion about the earth in twenty-nine days twelve hours and about forty-four minutes.

Locke's Elements of Natural Philosophy.

The alterations made by the commissioners were brought to the convocation then sitting, where they were *synodically* agreed upon. *Nelson.*

SYNOD, in astronomy, a conjunction or course of two or more stars or planets, in the same optical plane of the heavens.

SYNOD signifies also a meeting of ecclesiastical persons to consult on matters of religion. Of these there are four kinds, viz. 1. General or æcumenical, where bishops, &c., meet from all nations. These were first called by the emperors, afterwards by Christian princes; till in later ages the pope usurped to himself the greatest share in this business, and by his legates presided in them when called. 2. National, where those of one nation only come together, to determine any point of doctrine or discipline. The first of this sort held in England was that of Herudford or Hertfort, in 673; and the last was held by cardinal Pole, in 1555. 3. Provincial, where those only of one province meet, now called the convocation. 4. Diocesan, where those but of one diocese meet, to enforce canons made by general councils, or national and provincial synods, and to consult upon rules of discipline for themselves. These were not wholly laid aside, till, by the act of submission, 25 Hen.

VIII. c. 19, it was made unlawful for any synod to meet but by royal authority. See *COI XCII.* and *CONVOCATION.*

SYNODALS, or **SYNODIES**, were pecuniary rents (commonly of 2s.) paid to the bishop or archdeacon at the time of their Easter visitation, by every parish priest. They were thus called, because usually paid in synods; and as anciently bishops used to visit and hold their diocesan synods once. They are sometimes also denominated *synodalia*; but more especially procurations.

SYNODICAL EPISTLES are circular letters written by the synods to the absent prelates and churches; or even those general ones directed to all the faithful, to inform them of what had passed in the synod.

SYNOECIA, in Grecian antiquity, a feast celebrated at Athens in memory of Theseus's having united all the petty communities of Attica into one single commonwealth; the seat whereof was at Athens, where all the assemblies were to be held. This feast was dedicated to Minerva; and, according to the scholiast on Thucydides, it was held in the month Metagition.

SYNONYMISE, *v. a.* } *Lat. synonymia*; *Gr. ΣΥΝΩΝΥΜΟΣ*. To express the same thing in different words: the adjective corresponding.

This word fortis we may *synonymise* after all these fashions, stout, hardy, valiant, doughty, courageous, adventurous, brave, bold, daring, intrepid.

Camden's Remains.

These words consist of two propositions, which are not distinct in sense, but one and the same thing variously expressed; for wisdom and understanding are *synonymous* words here. *Tillotson.*

Fortune is but a *synonymous* word for nature and necessity. *Bentley's Sermons.*

When two or more words signify the same thing, as wave and billow, mead and meadow, they are usually called *synonymous* words. *Watts's Logick.*

SYNOPTICAL, *adj.* *Gr. συνοπτικος*. Affording a view of many parts at once.

We have collected so many *synoptical* tables, calculated for his monthly use. *Evelyn's Calendar.*

SYNOVIA, in anatomy, a term first used by Paracelsus and his school for the nutritious juice proper and peculiar to each part; as the *synovia* of the joints, &c.

SYNOVIAL GLANDS. See *ANATOMY.*

SYNTAGM, **SYNTAGMA**, *Gr. συνταγμα*, from *συν*, with, and *τασσω*, to order. A disposition of things according to order in literature: a regular treatise on any subject.

SYNTASIS, from *συν* with, and *τενω*, to stretch, in surgery, a preternatural distension of the parts.

SYNTAX, *n. s.* } *Gr. συνταξις*. A system; **SYNTAXIS**, } a number of things joined together: that part of grammar which teaches the construction of words.

They owe no other dependance to the first than what is common to the whole *syntax* of beings. *Glauville.*

I can produce a hundred instances to convince any reasonable man that they do not so much as understand common grammar and *syntax*. *Swift.*

SYNTAX, in grammar, the proper construction

or due disposition of the words of a language into sentences and phrases. See GRAMMAR.

SYNTHESIS, *n. s.* } *Gr. συνθεσις.* The act
SYNTHETIC, *adj.* } of joining: opposed to
 analysis: conjoining; compounding: opposed to
 analytic.

The *synthesis* consists in assuming the causes discovered and established as principles, and by them explaining the phenomena proceeding from them, and proving the explanations. *Newton's Opticks.*

Synthetic method is that which begins with the parts, and leads onward to the knowledge of the whole: it begins with the most simple principles and general truths, and proceeds by degrees to that which is drawn from them, or compounded of them; and therefore it is called the method of composition.

Watts's Logick.

SYNTHESIS, in logic, denotes a certain branch or method, opposite to analysis. In the synthetic method we pursue the truth by reasons drawn from principles before established or assumed, and propositions formerly proved; thus proceeding by a regular chain to the conclusion. Such is the method in Euclid's Elements, and most demonstrations of the ancient mathematicians, which proceed from definitions and axioms to prove propositions, &c., and from those propositions proved to prove others. This method we also call composition, in opposition to analysis or resolution. See ANALYSIS and ANALYTIC.

SYPIÆUM, an ancient town of the Bruttii, in Italy. See MURANUM.

SYPHAX, king of the Masæsyli, in Numidia. For his adventures, see NUMIDIA. He married Sophonisba. See SOPHONISBA. He died in prison at Rome, A. A. C. 201.

SYPHILIS. See MEDICINE, Index.

SYPHON, *n. s.* *Gr. σίφων.* A tube; pipe.

Take your glass, *siphon*, or crane; and draw it off from its last fæces into small bottles. *Mortimer.*

SYPHON. See HYDROSTATICS. Some uncommon phenomena in nature may be accounted for upon the principles of the syphon; as, for instance, that of reciprocating springs.

SYRACOSIA, festivals anciently held in Syracuse, for ten days annually, during which the women were chiefly employed in sacrificing. Syracosia was also the name of another annual festival, celebrated near the lake where it was supposed that Pluto had carried off Proserpina.

SYRACUSA, **SYRACUSÆ**, ancient names of Syracuse.

SYRACUSE, a celebrated city of Sicily, the capital of the island. It was built, according to Thucydides and Strabo, by Archias, one of the Heraclidæ, who came from Corinth into Sicily in the second year of the eleventh Olympiad, or about 732 years before the Christian era. It was named Syracusæ from Syraco, a marsh near it. This city was of a triangular form, and in its most flourishing state extended 180 stadia, or twenty-two English miles and four furlongs, in circumference, and was divided into four districts, viz. Ortygia, Acradina, Tycha, and Neapolis. There was also a fifth district, called Epipolæ; but, as it was thinly inhabited, it is often omitted by geographers. Each of the four chief districts formed separate cities, and were fortified with three citadels, and three-fold or

triple walls. Syracuse had also two spacious harbours, separated from each other by the island of Ortygia. See ORTYGIA. The greatest harbour was above 5000 paces in circumference, and its entrance 500 paces wide. The city was well built, and the houses were stately and magnificent.

What form of government first prevailed in the city is not known. The history is obscure till the time of Gelon, who was born in Gela, in Sicily. He signalised himself in a war carried on by Hippocrates tyrant of Gela against the Syracusans, whom he defeated in a pitched battle, and had well nigh taken their city. Having thus become very powerful, he soon seized on the sovereignty. Putting himself at the head of some Syracusan exiles, he marched towards that place, where he was received with loud acclamations by the faction to which they belonged; and by their means obtained possession of the city. Gelon, to people the capital of his new dominions, first demolished the neighbouring city of Camarina, and transplanted the inhabitants to Syracuse. Soon after, entering into a war with the Megareans, he defeated them, took and razed their cities, and in like manner transplanted the people. Syracuse thus became very powerful, and full of inhabitants; and the friendship of Gelon was courted both by Athens and Lacedæmon at the time of the Persian invasion. His assistance, however, was afterwards rejected, as he insisted upon being made commander-in-chief either of the fleet or the army. In the mean time the Carthaginians had entered into a treaty with the Persians; by which it was agreed that the former should attack those of the Greek name in Sicily and Italy, to divert them from assisting one another. Sicily was accordingly invaded by the Carthaginians with a vast army; but they were utterly overthrown by Gelon and his father-in-law Theron, prince of Agrigentum, as is related under the article CARTHAGE. After this victory, the people out of gratitude obliged him to take upon himself the title of king, which till that time he had refused. A decree also passed without opposition, by which the crown was settled on his two brothers Hiero and Thrasylulus after his death. The new king spent the remainder of his short reign in studying the happiness of his people. He died A. A. C. 471, after reigning four years.

Gelon was succeeded by his brother Hiero, whose character is differently drawn by historians. He was twice engaged in a war with the Agrigentines, and drove from their habitations the people of Catan and Naxos, settling in their room a colony of Syracusans and Peloponnesians. Hiero I. died A. A. C. 459, and was succeeded by Thrasylulus; who, proving a tyrant, was in ten months driven out, and a popular government restored, which continued fifty-five years.

Several persons for some time aspired at the sovereignty; to prevent which they had recourse to petalism; but, being productive of great inconveniences, the law was repealed soon after it had been enacted. See PETALISM. About this time the Syracusans entered into a war with the Siculi, which terminated in the subjection of the

latter. Syracuse now became so powerful that it in a manner gave law to the whole island. The Leontines disputing the supremacy of the Syracusans, their territory was laid waste, and their city reduced to great straits. Leontini was an Athenian colony; and this furnished the Athenians, who had already meditated the conquest of Sicily, with a pretence to attack the Syracusans with their whole force. But the Leontines, sensible that their pretended allies aimed at the conquest of the whole island, concluded a peace with Syracuse. In A. A. C. 416, a dispute happening between the inhabitants of Ægesta, or Segesta and Selinus concerning some lands which the latter had seized, the Segestines applied for assistance to Agrigentum, Syracuse, and even to Carthage. But, as none of these states chose to interest themselves in their quarrel, they applied at last to the Athenians, who joyfully accepted of the opportunity of again interfering in the affairs of Sicily. With the most sanguine expectations the Athenians landed 7000 men in Sicily, under Nicias, possessed themselves of a strong post, and put the Syracusans to flight.

In the mean time the Syracusans received assistance from the Lacedæmonians under the command of an experienced officer named Gylippus, who arrived just in time to prevent Syracuse from surrendering. At the head of 7000 foot and 200 horse he made directly for Epipolæ, where Nicias had fortified himself in a castle named Labdalon; he drew up his small army under the walls; and sent a herald to Nicias to tell him that he would allow him only five days to leave Sicily. Nicias returned no answer; but Gylippus soon after stormed the fort, and put to the sword all the Athenians in it. This opened a way into the city, where he was received with loud acclamations. The fortune of the war was again changed. The Athenians gained an advantage by land, but were next day defeated with great loss. The Syracusans received fresh supplies from Corinth, and the Athenians from Attica. Many engagements both by sea and land took place, in which the success was ultimately in favor of the Syracusans. At last the Athenian affairs were totally ruined by the loss of a sea-fight, in which sixty of their ships were taken or destroyed, and the rest left quite unserviceable. In this desperate situation it was determined to abandon their ships, and retire that night to the city of their confederates. But this measure was delayed from a piece of false intelligence; and Nicias did not march out till the third day after. The Athenians and their allies also marched out to the number of 40,000; but finding themselves shut up on all sides, and being obliged to fight their way through every outlet, they soon sunk into despair. Nicias did his utmost to encourage them; and at last they marched out in two bodies. The vanguard, led by Nicias, continued to advance in good order; but half the rear, commanded by Demosthenes, lost their way in the night, and were obliged to surrender. Nicias, being informed of this misfortune, offered to pay the whole expense of the war, provided he was allowed to march off with his men. But, this being rejected, he set out,

though galled all the way by showers of darts from his enemies. Arriving at a river called Asmarus, they rushed into it without order; in which confusion the Syracusan cavalry attacked them so desperately that 18,000 perished, and the river, for many miles, was dyed with their blood. The remainder surrendered, on condition of having their lives saved; but the terms were shamefully broken by the Syracusans. The generals were first ignominiously whipped, and then put to death: the soldiers were sent to labor in quarries, where they were allowed only two small measures of flower and one of water a day; and where, being crowded, they suffered inexpressible miseries for many months. Most of them perished by this cruel treatment, and the few who survived were sold for slaves.

The war was scarcely ended when a new and formidable invasion by the Carthaginians took place; but the event of that expedition was as unfortunate to the Carthaginians as the former had been, of which a particular account is given under the article CARTHAGE. See also AGRIGENTUM. In the mean time, however, a considerable revolution had happened in Syracuse. Dionysius, a man of great valor and eloquence, acquired such influence with the populace, that step by step he attained to sovereign power, possessed himself of the citadel, where all the arms and provisions were kept, and publicly took the title of king of Syracuse, A. A. C. 404. The Syracusans did not tamely submit to their new master: but Dionysius managed matters so well, that their frequent revolts answered no other purpose than more certainly to entail slavery on themselves; and he was allowed to possess the throne, without much opposition, till his death, A. A. C. 366. See DIONYSIUS I., and SICILY.

On the death of Dionysius, he was succeeded by his son, Dionysius II. He was naturally of a mild and peaceable temper, averse from cruelty, and inclined to learning; but his father, to whom all merit, even in his own children, gave umbrage, stifled as far as possible his good qualities by a mean education. He no sooner ascended the throne than Dion, brother to Aristomache the other wife of Dionysius the elder, undertook to correct the faults of his education, and to inspire him with thoughts suitable to the high station in which he was placed. For this purpose he sent for the philosopher Plato, under whose care he put the young king. This produced a reformation on Dionysius; but the courtiers, dreading the effects of the philosopher's instructions, prevailed on him to banish Dion, and to keep Plato himself in a kind of imprisonment in the citadel. At last, however, he set him at liberty; upon which Plato returned to his own country. Dion, in the mean time, visited several of the Grecian cities, and at last took up his residence in Athens; but the honors which were every where paid him raised such jealousies in the breast of the tyrant that he stopped his revenue and caused it to be paid in to his own treasury. In a short time Dionysius again sent for Plato, but, finding it impossible to dissolve the friendship between him and Dion, disgraced, and placed him in a very dangerous situation, in the midst of assassins who hated him. See PLATO.

Not daring, however, to offer him any violence, he allowed him soon after to depart; revenging himself on Dion, whose estate he sold, and gave his wife Arete in marriage to Timocrates, one of his own flatterers. Dion now resolved to revenge himself on the tyrant for the many injuries he had sustained, and at once to deliver his country from the oppression under which it groaned. He began with raising foreign troops privately, by proper agents. Many Syracusans of distinction entered into his scheme, and gave him intelligence of what passed in the city; but of the exiles only twenty-five joined him, with about 800 men. He arrived at the port of Minoa, near Agrigentum. Here they received intelligence that Dionysius had set sail for Italy with a fleet of eighty galleys. On this Dion resolved to take advantage of the tyrant's absence; and immediately set sail for Syracuse. On his march he prevailed upon the inhabitants of Agrigentum, Gela, Camarina, and other cities, to join him. As soon as he entered the territories of Syracuse, multitudes flocked to him; and, as nobody appeared to oppose him, he boldly entered the city, where he quickly found himself at the head of 50,000 men. Seven days after Dion's arrival, Dionysius returned and entered the citadel by sea. Finding his affairs in a desperate situation, he had recourse to artifice; and having amused the Syracusans by a feigned negotiation, until he observed that they kept a negligent guard, he attacked them all at once with such fury that he had almost taken the city. But Dion encouraged the soldiers by his example so much that he at last obtained a complete victory; for which they presented him with a crown of gold. Dionysius was obliged to fly to Italy.

It was not long, however, before the ungrateful Syracusans began to confer quite different rewards on their benefactor. Dion, having opposed a proposal for a new division of lands, was obliged to leave the city and reside some time at Leontini, where he was received with respect. In the mean time the citadel still continued in the hands of the adherents of Dionysius. Being blocked up on all sides, they were reduced to great straits, and were actually making proposals of capitulation, when Nypsius, an experienced general, and greatly attached to Dionysius, appeared with a numerous squadron of galleys, and a large fleet of transports laden with provisions. The general landed his men, and got them into the citadel; but almost all his galleys and ships laden with corn were sunk or taken. This victory proved the ruin of the Syracusans; for, giving themselves up to riot and debauchery, the enemy sallied out in the night-time from the citadel, and massacred the citizens without mercy. An embassy was then sent to Dion, entreating him to return and save the city a second time. To this he agreed, and instantly set out on his march; but in the mean time, as the soldiers of Dionysius, satiated with the slaughter, had retired into their fortress, the ungrateful Syracusans began to repent of their having sent an embassy to Dion. The chief commanders, therefore, sent messengers to stop his march; but, as some of his friends sent deputies to him at the same time, contradicting this

message, he proceeded on his journey. The infatuated mob seized the gates to dispute his entrance; but they paid dear for their frenzy. The Dionysians again sallied out upon them, and made a second massacre. As they knew that Dion was hastening to the relief of the city, they endeavoured to destroy it entirely before his arrival; for, after they had murdered all the inhabitants they could find, they set fire to the houses, by which great numbers perished. But, during this confusion, Dion arrived; and, having briskly attacked the enemy, at last defeated them with great slaughter, driving the remainder into the citadel. The citadel soon after surrendered; and Dion allowed Apollocrates the tyrant's son, who commanded there, to retire with five galleys to his father. As soon as Dion entered the citadel, he was met by his sister and wife Areta, whom he received with affection, notwithstanding her having lived so long with Timocrates. He then left the Syracusans in possession of the citadel, rewarded his followers, dismissed his guards, and lived like a private citizen. In a short time after he lost his life, through the base treachery of Calippus, or Gylippus, who pretended to be his intimate friend, and who immediately after caused his wife and sister to be carried to prison. See *DION*.

Calippus, having thus removed Dion, soon made himself master of Syracuse, where he committed all manner of cruelties; but was driven out, and forced to fly to Rhegium, where he was murdered with the same dagger wherewith he had killed Dion. In 350 B. C. Dionysius again made himself master of Syracuse; and, being exasperated by his past misfortunes, tyrannized worse than ever. The Syracusans first had recourse to Ictetas tyrant of Leontini; but, as the Carthaginians took this opportunity to invade them with a powerful fleet and army, they were obliged to apply to the Corinthians. By them Timoleon, a celebrated commander, was sent to assist the Syracusans, whom he found in a very distressed situation; Ictetas being master of the city, the Carthaginians of the harbour, and Dionysius of the citadel. As all parties were equally the enemies of Dionysius, he found it impossible to hold out, and therefore surrendered himself to Timoleon, by whom he was sent to Corinth; where at last he was reduced to the necessity of teaching a school for his support.

After the expulsion of the tyrant, Timoleon withdrew to Catania, leaving only 400 Corinthians, under the command of an experienced officer named Leon, to guard the citadel. These were immediately besieged by Ictetas and the Carthaginians, but Timoleon relieved them in spite of all opposition; and having dispersed emissaries through the army of Mago the Carthaginian general, exhorting the mercenary Greeks to forsake him, he was so much intimidated that, in spite of all the remonstrances Ictetas could make, he set sail for Africa, leaving his colleague to carry on the war in the best manner he could. The day after the departure of Mago, Timoleon assaulted the city so briskly that the troops of Ictetas were driven from the walls, and the Corinthians became masters of the place. Timoleon

invited the inhabitants to assist in demolishing the citadel and other castles, which he called nests of tyrants; after which he caused edifices to be erected in the place where the citadel had stood, for the administration of justice. He found the city in a most miserable situation, and almost a desert. He supplied the city with inhabitants from Corinth and other cities of Greece, and distributed the lands among them gratis; but sold the houses, and with the money arising from the sale established a fund for the support of the poor. Having thus restored Syracuse, he in like manner delivered all the Greek cities of Sicily from the tyrants who had taken possession of them, all of whom he put to death. After this he resigned his authority, and led a retired life, honored in the highest degree by the Syracusans, and by all the cities in Sicily. After his death he was honored as a god.

For twenty years the Syracusans enjoyed the fruits of Timoleon's victories; but, new disturbances arising, another tyrant started up, who exceeded all that had gone before him in cruelty and other vices. This was the celebrated Agathocles, of whose exploits against the Carthaginians, some account is given under the articles AGATHOCLES, AGRIGENTUM, CARTHAGE, and SICILY. But further particulars belong to this article. In two years he subdued all the Greek part of Sicily. He next committed great devastations in the Carthaginian territories, their general Hamilcar not offering to disturb him. This perfidious conduct greatly incensed the people of those districts against Hamilcar, whom they accused before the senate. He died, however, in Sicily; and Hamilcar the son of Gisco was appointed to succeed him in the command of the forces. The last place that held out against Agathocles was Messina, whither all the Syracusan exiles had retired. Pasiphilus, Agathocles's general, cajoled the inhabitants into a treaty; which Agathocles paid no regard to, but, as soon as he was in possession of the town, cut off all those who had opposed his government; for, as he intended to prosecute the war with the utmost vigor against Carthage, he wished to destroy as many of his Sicilian enemies as possible. The Carthaginians in the mean time having landed a powerful army in Sicily, an engagement ensued, in which Agathocles was defeated with the loss of 7000 men. After this defeat he was obliged to shut himself up in Syracuse, which the Carthaginians immediately invested, and most of the Greek states in the island submitted to them. Agathocles seeing himself stripped of almost all his dominions, and his capital itself in danger of falling into the hands of the enemy, determined to transfer the war into Africa, and lay siege to the enemy's capital. For this purpose he contrived to carry over 14,000 men, and land them with little opposition. As soon as his forces were landed, Agathocles burnt his fleet, that his soldiers might have no possibility of flying. He first advanced to a place called the Great City. This, after a feeble resistance, he took and plundered. Hence he marched to Tunis, which surrendered on the first summons; and Agathocles levelled both places with the ground.

The Carthaginians were at first thrown into the greatest consternation; but, recovering themselves, the citizens took up arms, and in a few days they had an army of 40,000 foot and 1000 horse, with 2000 armed chariots. The command of this army they entrusted to Hanno and Bomilcar, two generals between whom there subsisted a great animosity. This occasioned the defeat of their whole army, with the loss of their camp. Upon this defeat the Carthaginians, according to their barbarous superstition, offered up 200 children, and other 300 voluntary human sacrifices. In Sicily, Hamilcar still resolved to storm the city, did his utmost to conceal from the Syracusans the intelligence of Agathocles's victory; but in vain, for Agathocles got it conveyed by a galley. Hamilcar then erected scaling ladders, and began his attack upon Syracuse, but, though at first he was somewhat successful, he was soon repulsed with great loss. Raising the siege, he over-ran the country and took some towns in alliance with Syracuse; after which he renewed his attack on the city in the night, but was completely defeated, his troops slaughtered, and himself taken prisoner, carried into Syracuse, and beheaded.

About this period the Agrigentines, finding the Carthaginians and Syracusans had greatly weakened each other, thought it a proper time to seize the sovereignty of the whole island, and therefore commenced a war against both; in which they had such success that they took many capital towns both from the Carthaginians and Syracusans.—In the mean time Agathocles was extremely successful in Africa. He took most of the towns of note in the Carthaginian territories; and hearing that Elymas king of Libya, their ally, was coming against him, he entered Upper Libya, and gave him a complete overthrow, slaughtering a great number of his troops with his general at their head. After this he advanced against the Carthaginians with such expedition that he surprised and defeated them, with the loss of 2000 killed, and a great number taken prisoners. He next prepared for the siege of Carthage itself; and advanced within five miles of that city; but, notwithstanding the great losses they had sustained, the Carthaginians, with a powerful army, encamped between him and their capital. In this situation Agathocles received advice of the defeat of the Carthaginian forces before Syracuse, along with the head of Hamilcar. Upon this he immediately rode up to the enemy's camp, and, showing them the head, gave them an account of the total destruction of their army before Syracuse. This threw them into such consternation that in all human probability Agathocles would have made himself master of Carthage, had not an unexpected mutiny arisen in his camp, which gave the Carthaginians time to recover from their terror. The year following an engagement happened, in which neither party gained any great advantage; but, soon after, the tyrant, notwithstanding all his victories, found himself unable to carry on the war alone; and therefore endeavoured to gain over Ophellas, one of the captains of Alexander the Great. In this he succeeded: Ophellas brought an army to his assistance through

many trials; in reward for which, Agathocles cut him off by treachery, and then by promises persuaded his troops to serve under himself.

Agathocles now, finding himself at the head of a numerous army, assumed the title of king of Africa, intending to complete his conquests by the reduction of Carthage. He began with the siege of Utica, which was taken by assault. After this he marched against Hippo Djarrhytus, the Biserta of the moderns, which was also taken by storm; and after this most of the people bordering upon the sea coasts, and even those who inhabited the inland parts, submitted. But in the midst of this success the Sicilians formed an association to recover their liberty; which obliged the tyrant to return home, leaving his son Archagathus to carry on the war in Africa. Archagathus, after his father's departure, greatly extended the African conquests. He sent Eumachus at the head of a large detachment to invade some of the neighbouring provinces, while he himself, with the greatest part of his army, observed the motions of the Carthaginians. Eumachus, falling into Numidia, first took the great city of Tocas, and conquered several of the Numidian cantons. Afterwards he besieged and took Phellina; which was attended with the submission of the Asphodelodians, a nation (says Diodorus) as black as the Ethiopians. He then reduced several other cities; and, being at last elated with such a run of good fortune, resolved to penetrate into the more remote parts of Africa. Here he at first met with success; but, hearing that the barbarous nations were advancing in a formidable body to give him battle, he abandoned his conquests, and retreated with the utmost precipitation towards the sea-coasts, after having lost many men. This unfortunate expedition made a great alteration for the worse in the affairs of Archagathus. The Carthaginians, hearing of Eumachus's bad success, resolved to repair their former losses. They divided their forces into three bodies; one they sent to the sea-coasts; another into the Mediterranean parts, and the last to Upper Africa. Archagathus divided his forces likewise into three bodies; one he sent to observe the Carthaginian troops on the coasts, and advance afterwards into Upper Africa; another, under Æschriion, he sent into the heart of the country; and with the last, which he led in person, he kept nearer Carthage, preserving a communication with the other two, to send them succors, or recall them, as the exigency should require. The Carthaginian troops sent into the heart of the country were commanded by Hanno, a general of great experience, who, being informed of the approach of Æschriion, laid an ambuscade for him, into which he was drawn and cut off with 4000 foot and 200 horse. Himilco, who commanded the Carthaginian forces in Upper Africa, having advice of Eumachus's march, immediately advanced against him. An engagement ensued, in which the Greeks were almost totally cut off, or perished with thirst after the battle; out of 8000 foot only thirty, and of 800 horse only forty having escaped. Archagathus, receiving the news of these two defeats, immediately called in the detachments he had sent out. He was, however, soon hemmed

in on all sides in such a manner, as to be reduced to the last extremity for provisions, and ready every moment to be swallowed up by his numerous enemies. In this distress, he sent an express to his father informing him of his losses. Hereupon Agathocles, leaving the care of the Sicilian war to Leptines, procured the assistance of eighteen Etruscan ships, with which he fought the Carthaginian squadron then on the coast, took five of their ships and made prisoners of their men. Having thus become master of the port, and secured a passage into it for trading vessels, plenty was soon restored; of which, taking a sufficient supply for himself, he immediately sailed for Africa. Upon his arrival he found his forces to consist of 22,000 Greeks, Samnites, Etruscans, Celtes, and Africans; besides 1500 horse. He offered the enemy battle, but they declined. He, however, forced them to action, attacked the camp with his usual bravery, and in all probability would have gained a complete victory, had not his mercenaries deserted him. The barbarous sacrifice made by the Carthaginians, and its dreadful consequences to their whole army, are related under *CARTHAGE*, as well as its consequences to Agathocles, who with difficulty escaped from his enemies and his own enraged soldiers, who murdered his sons, and made peace with Carthage. After all this reverse of fortune, Agathocles returned to Italy, gathered a new army, relieved Corcyra, and forced Cassander to raise the siege of it; burned the Macedonian fleet; avenged the murder of his wives and children; met with his old troops, who had deserted him in Africa; defeated and massacred them all; ravaged the coasts of Italy; and took Hipponium. At last he was poisoned, some say by his grandson, others by one Moenon, A. A. C. 289, in the twenty-eighth year of his reign, and ninety-fifth of his age.

After Agathocles's death, a succession of tyrants followed, till at last the city, being held by two rivals, Toenion and Sosistratus, who made war within the very walls, Pyrrhus king of Epirus was invited into Sicily, to put an end to these destructions. He willingly complied with the invitation: and was every where received with loud acclamations as the deliverer not only of Syracuse, but of all Sicily. Puffed up with the expectation of reducing the whole island, he caused his son to take upon him the title of king of Sicily; but in the mean time having displeased the Sicilians, by his arbitrary behaviour, they deserted from him in such numbers that he was glad to set out for Italy. He embarked in the ships which he had brought with him from Italy; but was met at sea by the Carthaginians, who sunk seventy of his vessels, and dispersed or took the rest; so that he saved himself in Italy only with twelve vessels, the poor remains of a fleet of 200 sail.

After the departure of Pyrrhus, Hiero II. the son of Hierocles, a descendant of Gelon the first king of Syracuse, was chosen general of the forces, along with another named Artemidorus. The two generals earnestly wished to put an end to the confusion and disorder which reigned in the city; for which reason they entered it at the head of their forces. On this occasion Hiero

discovered extraordinary talents for government. By mere dint of insinuation and address, without shedding blood or hurting a single citizen, he so gained the affections of all, that he was invested with the whole civil as well as military power in the state. Soon after this he married the daughter of one of the first citizens; and, having distinguished himself by his exploits against the Mamertines, was unanimously elected king of Syracuse, A. A. C. 265. Some time after Hiero's accession to the throne, he again defeated the Mamertines, and reduced them to such straits that they were obliged to call in the Romans to their assistance. The consequences of this have been fully related under the articles *ROME* and *CARTHAGE*. Hiero, who had allied himself with the Carthaginians, being himself defeated by the Romans, and finding his allies unable to protect him against the power of that republic, concluded an alliance with them, and continued faithful to them even in the time of the second Punic war, when they were in the greatest distress. In his reign flourished the celebrated mathematician Archimedes, whose genius he employed in fortifying the city of Syracuse, by innumerable machines, in such a manner as rendered it absolutely impregnable to every method of attack known at that time. See *ARCHIMEDES*. Hiero II. died about A. A. C. 211.

Hiero was succeeded by his grandson Hieronymus; but he imprudently forsook the counsels of his grandfather, and entered into an alliance with the Carthaginians. Soon after this he was murdered in consequence of his tyranny and cruelty, and the greatest disorders took place in the city; which Hannibal, though then in Italy, found means to foment, in hopes of keeping the Syracusans in his interest. This indeed he effected; but as his own affairs in Italy began to decline (see *CARTHAGE*) he could not prevent Marcellus from landing in Sicily with an army which the Sicilians were unable to resist. Syracuse was soon invested; but the machines invented by Archimedes baffled all attempts to take it by assault. These were so stupendous and powerful, that ships were dashed to pieces by the huge rocks they discharged, and the troops were more annoyed by the showers of arrows and stones than modern armies are by musketry. The consuls, finding themselves thus defeated in every attempt, turned the siege into a blockade, reduced most of the other places in the island, and defeated the forces which were sent against them; and at last Marcellus made himself master of Syracuse itself, of which the following account is given by Mr. Hooke:—"He took the opportunity of a festival, when the soldiers and citizens had drunk plentifully, to make a detachment scale the walls of Tyche, in that part of it which was nearest to Epipolæ, and which was ill guarded. He presently after possessed himself of Epipolæ; whereupon the inhabitants of Neapolis, as well as Tyche, sent deputies to him and submitted. Marcellus granted life and liberty to all of free condition, but gave up those quarters of the city to be plundered. Notwithstanding this there was a great deal yet to do. Acradina and Ortygia, which were strongly fortified, still held out; Hippocrates and Himilco arrived with

their troops to the relief of the besieged, and the Romans were forced to exert all their bravery and skill to maintain the advantages they had gained. But now a plague made terrible havoc in both armies. At the first breaking out of the pestilence the Sicilians, who served under Hippocrates and Himilco, disbanded themselves and returned to their respective homes; but all the Carthaginian soldiers perished together with those two generals. The Romans suffered less by the infection; because, having been a long time before Syracuse, they were seasoned to the air and water of the country. About this time Bomilcar arrived on the coast of Sicily from Carthage with a fleet of 130 galleys and 700 ships of burden; but was long hindered by contrary winds from doubling the Cape of Pachynum. Epicides, fearing the Carthaginians might sail back to Africa, left the command of Acradina to the generals of the mercenaries, and went to Bomilcar in order to persuade him to fight the Roman fleet. The admiral would not engage, but sailed away to Tarentum with all his galleys, ordering his ships of burden to return to Africa. Epicides, thus frustrated of his hopes, and knowing himself unable to defend a city already half taken, retired to Agrigentum; whereupon the Syracusans massacred the commanders appointed by him, chose new prætors to govern in the town, and sent deputies to Marcellus to treat of peace. In the mean time the deserters, fearing to be given up to the vengeance of the Romans, persuaded the mercenaries that they also would have the same fate. Instantly the soldiers ran to arms, put to death the new prætors, together with many of the Syracusans, and plundered part of the city. After this slaughter they chose six generals, three to command in Acradina, and three in Ortygia. Upon the return of the deputies from Marcellus, the mercenaries finding that their case was different from that of the deserters, and that there was no design against their lives, became perfectly satisfied, and the negotiations went on. During the course of the treaty, Marcellus found means to corrupt Mericus, a Spaniard, one of the six generals chosen by the soldiers, and engaged him to admit the Romans into that part of the city where he commanded. Mericus, the better to accomplish this design, feigned an extraordinary zeal for the preservation of the place; pretended not to like that deputies should have leave to go out and in at pleasure; and proposed that, for the greater security of the town, each general should have a distinct quarter assigned him, and be responsible for any neglect of duty in it. The motion was agreed to; and upon the division, that district of Ortygia which extended from the fountain of Arethusa to the mouth of the great port fell to his care. Marcellus, informed of what was done, took his measures accordingly. He sent a body of troops to that side where Mericus commanded, and the Spaniards admitted them at the gate of Arethusa. At the same time the proconsul ordered a false attack to be made on Acradina; which drawing almost all the soldiers of the garrison thither, Ortygia was in a manner left defenceless. Foreseeing this he had detached another party of soldiers to take advantage of it. These entered

Ortygia almost without fighting; upon which the deserters made their escape, the Romans giving them way; and the Syracusans in Acradina, thus delivered from the fear of the deserters, immediately opened their gates to Marcellus, who thereby became master of the whole city. And now the conqueror, who is said to have wept during the siege with compassion for the inhabitants, gave up both Ortygia and Acradina to be plundered by his army, after he had secured the late king's treasures for the use of the republic, and the statues, paintings, and principal ornaments of Syracuse to illustrate his triumph. The soldiers had orders to spare the lives of the citizens; but they were cruel in their avarice, slew many of them, and among the rest the incomparable Archimedes. He was very intent on a demonstration in geometry, and calmly drawing his lines, when a soldier entered the room and clapped a sword to his throat. "Hold (said Archimedes) one moment, and my demonstration will be finished." But the soldier, equally regardless of his prayer and his demonstration, killed him instantly. There are different accounts of the manner of his death, but all agree that Marcellus regretted it extremely, and showed a singular favor to his relations for his sake.

The apostle Paul spent three days in this city in his voyage to Rome, and Christianity was early planted in it. It continued subject to the western empire till its declension, when, the island of Sicily being ravaged by different barbarians, the capital also underwent various revolutions. In 675 it was taken and plundered by the Saracens, who, about 827, had subdued all Sicily, and destroyed much of its ancient grandeur (see CONSTANTINOPLE); but in 1090 it was recovered by Roger, earl of Sicily. It has since shared the fortune of the rest of Sicily. Near this port there was a sea engagement, in 1718, between the Spaniards and the British, in which the former were defeated and obliged to leave Sicily; but, in 1735, they retook Syracuse. Like the rest of Sicily it is much subject to earthquakes; and, in 1693, was almost totally destroyed by one.

At present the only inhabited part of Syracuse is a south-east portion, containing Ortygia and part of Acradina. It is insulated, walled, and entered by drawbridges. The streets are regular but narrow; the houses tolerably built. The population is not above 15,000. The cathedral or principal church is the ancient temple of Minerva.

SYRIA, a very ancient country or kingdom of Asia, lying between the Mediterranean on the west, the Euphrates on the east, and Arabia Deserta, Phœnicia, and Palestine on the south, or, as Crutwell describes it, 'this name is given to the whole space contained between two lines drawn the one from Alexandretta to the Euphrates, and the other from Gaza in the desert of Arabia; bounded on the east by this desert, and on the west by the Mediterranean.' But Lempriere says that ancient Syria, whose boundaries are not accurately ascertained by the ancients, was bounded on the east by the Euphrates, north by mount Taurus, west by the Mediterranean, and south by Arabia.

This country appears in the patriarchal age to

have been divided into a great number of cantons or petty principalities. Very early after the flood it went by the general name of Aram, from Aram the youngest son of Shem, who settled in it. Hence the different cantons were named Aram-naharaim, Aram-zobah, Aram-maachah, and Aram-zehob. Within a few centuries afterwards it had obtained its present name of Syria; for we find Bethuel the nephew, and Laban the grand-nephew of Abraham, styled Syrians, even in the patriarchal age. See Gen. xxv. 20. It is a piece of learned folly, therefore, to quote Plutarch's derivation of this name from the fabulous hero Syrus, the son of Apollo. Much more credit is due to those etymologists who suppose it to be a contraction of the name Assyria, which the best historians, etymologists, and chronologists, derive from Ashur, the second son of Shem. See ASSYRIA. Lempriere makes it so very extensive as to have comprehended 'Phœnicia, Seleucia, Judea or Palestine, Mesopotamia, Babylon, and Assyria;' which last name, he adds, was used indifferently with Syria by some ancient authors. But, be that as it may, all the petty states, provinces, principalities, and cantons, into which Syria Proper was originally divided, appear to have been afterwards reduced under subjection to the four principal ones, Zobah, Damascus, Hamath, and Geshur. Afterwards the whole country was divided into two parts only; viz. Cœlesyria and Phœnicia; though the Phœnicians, Idumeans, Jews, Gazites, and Azorites, inhabiting the whole country of the Philistines, were included. After the death of Alexander, Syria, in the great extent of the word, was divided, according to Strabo, into Comagene, Seleucis of Syria, Cœlesyria, Phœnicie on the sea-coast, and Judea in the midland. Ptolemy, however, subdivides these; and in the Proper Syria reckons only Comagene, Pieria, Cyrrhæstia or Cyrrhæstia, Seleucis, Cassiotis or Casiotis, Chalybonitis, Chalcedice or Chalcedene, Apamene, Laodicene, Phœnicia Mediterranea, Cœlesyria, and Palmyrene. It has long been, and still is, named by the Arabs, the descendants of Ismael, Barr el Sham, or the country of Shem.

The history of the ancient Syrians, till the time of their being carried away by the king of Assyria, is altogether unknown, excepting a few particulars to be gleaned from Scripture, which it is unnecessary here to repeat. During the continuance of the empires of Babylonia and Persia, the history of Syria affords nothing peculiar, being involved in that of these countries; but after the death of Alexander the Great, who had subdued all these empires, it became a very considerable kingdom, which makes a conspicuous figure in ancient history.

At the death of Alexander, the name of Syria was not confined to Syria properly so called, but comprehended all those vast provinces of Upper Asia which formed the Persian empire; being, in its full extent, bounded by the Mediterranean upon one side, and the river Indus on the other. Seleucus, one of the generals of Alexander the Great, after the death of that conqueror, being made governor of Babylon, was tempted, by the example of Alexander's other captains, to set up for himself. Eumenes, who had sincerely at

heart the interest of Alexander's family, solicited his assistance against Antigonus, who had openly revolted; but Seleucus not only refused his assistance, but attempted to destroy Eumenes himself with his whole army, by cutting the sluices of the Euphrates, and laying under water the whole plain where they were encamped. Eumenes, however, escaped the danger without the loss of a man. Upon this Seleucus endeavoured to gain over his troops; but, finding that impossible, he made a truce with Eumenes, and granted him a safe passage through his province; but at the same time sent an express to Antigonus, desiring him to fall upon him before he was joined by the governors of Upper Asia. Antigonus did not fail to follow his advice; but, having thus prevailed against Eumenes through treachery, he next thought of bringing Seleucus himself under subjection. On his return to Babylon, therefore, after having been feasted with his whole army by Seleucus, he demanded an account of the revenues of his province. This being refused, Antigonus was so much exasperated that Seleucus, not thinking himself a match for him, fled into Egypt. By the flight of Seleucus, Antigonus was left master of all his provinces; but, his son Demetrius being afterwards defeated by Ptolemy at Gaza, Seleucus began to think of recovering what he had lost. Being furnished by Ptolemy with 1000 foot and 200 horse, he set out with that slender force to attempt the recovery of Babylon. Nothing could have a more desperate appearance than this undertaking; yet Seleucus on his arrival at Carrhæ in Mesopotamia, partly by force and partly by persuasion, prevailed on the Macedonians, who garrisoned that place, to revolt from Antigonus and join him. Being thus reinforced, he entered the territories of Babylon, where new supplies were continually added to his army; his ancient subjects flocking to him from all parts, and declaring themselves ready to stand by him with their lives and fortunes. This happened in consequence of the lenity with which they had been treated by Seleucus; whereas Antigonus was universally detested on account of his severity. As he approached the city, those who favored Antigonus retired into the citadel, but were soon obliged to surrender; and in that fortress Seleucus found his children, friends, and domestics, whom Antigonus had kept prisoners ever since his flight into Egypt. Seleucus having thus made himself master of Babylon, in A. A. C. 312, began to prepare for encountering Antigonus, who he knew would soon attack him with all his force. Nicanor, governor of Media under Antigonus, first advanced against him at the head of 10,000 foot and 7000 horse; but Seleucus, with only 3000 foot and 400 horse, having drawn him into an ambush, cut off almost the whole of his army, and the surviving soldiers willingly enlisted under him. The consequence of this victory was the submission of all Media and Susiana; which alarming Antigonus, he sent his son Demetrius with an army of 5000 Macedonian foot, 10,000 mercenaries, and 4000 horse. Seleucus was then in Media; and Patrocles, whom he had left to take care of Babylon, finding his force inadequate to that purpose, com-

pelled the inhabitants to leave the city and disperse themselves in the adjacent countries, while he himself, with what troops he had, retired into two forts, which he thought could easily be defended. When, therefore, Demetrius entered Babylon, he was surprised to find it deserted, upon which he instantly attacked the forts. One was quickly reduced; but, as the other held out till the expiration of the time which had been allowed him by his father, he left 5000 foot and 1000 horse under Archelaus to carry on the siege. With the rest he marched away, suffering his soldiers to live at discretion as he went along; which so provoked the Babylonians that they were ever after attached to Seleucus as if he had been their natural prince. On the return of Seleucus to Babylon, he easily drove out the troops left by Antigonus, recovered the castle which he had garrisoned, and settled his authority on such a firm foundation that it could never afterwards be moved. Having then marched again into Media, he defeated and killed with his own hand Nicanor, whom Antigonus had sent against him; after which, having settled the affairs in Media, he reduced all Persia, Bactria, and Hyrcania, subjecting to his new kingdom these and all the other provinces on this side the Indus which had been conquered. Seleucus, being now master of all the countries which lie between the Euphrates and the Indus, took the title of king of Babylon and Media. But not satisfied with these possessions, ample as they were, he crossed the Indus, to conquer those regions which had submitted to Alexander beyond that river. But, during the time that the generals of Alexander had been making war upon his family and upon one another, Sandrocottus, a native of India, had driven out the Macedonians and made himself master of the whole country. See SANDROCOTTUS. He opposed Seleucus with an army of 600,000 men, and a prodigious number of elephants; which intimidated the Macedonian so much that he offered to leave Sandrocottus in quiet possession of his dominions, provided he would furnish him with 500 elephants. To this Sandrocottus readily assented; upon which Seleucus marched back into the west against Antigonus, and, in conjunction with Lysimachus and Ptolemy, engaged and totally defeated and killed him at Ipsus. See ANTIGONUS I. After this Seleucus marched into Upper Syria, which he reduced entirely, and built the city of Antioch on the Orontes. In the same country he built several other cities; one of which he called Seleucia, from his own name; another Apamea, from his wife Apama, the daughter of one Artabazus a Persian; and a third Laodicea, from his mother Laodice. He first entered into an alliance with Demetrius, and married Stratonice his daughter; but soon after assisted Lysimachus and Ptolemy to deprive him of the best part of his dominions. Thus, Demetrius being reduced so low that he could give him no farther jealousy, Seleucus built another city, called likewise Seleucia, seated where Bagdad now stands. Besides these, he built many others; sixteen of which he called Antioch, from his brother or son Antiochus; nine Seleucia; three Apamea; one Stratonicea; and six Laodicea, from his relations

above-mentioned. In 284 Seleucus entered into a war with Lysimachus, with whom he had hitherto lived in amity. Out of thirty-six general officers, left by Alexander the Great, they two only survived, and both were upwards of seventy years old; yet both were filled with the ambition and animosity of young men. The two armies met at a place called Curopidion in Phrygia, where an obstinate engagement took place. Victory was long doubtful; but at last Lysimachus was run through with a spear, and died on the spot; on which his troops fled, and left Seleucus master of all their baggage. This victory added to the possessions of Seleucus all those provinces which had formerly been subject to Lysimachus. He exulted much in his good fortune; boasting that he was now the last of Alexander's captains, and by this victory became, as he styled it, the conqueror of conquerors; whence he is generally called Nicator, or the conqueror. His triumph, however, was but short lived; for seven months after, as he was marching towards Macedon to take possession of that kingdom, he was treacherously murdered by Ptolemy Ceraunus, on whom he had conferred innumerable favors. Philetaerus, prince of Pergamus, purchased his body at a great price from Ptolemy, and sent it to his son Antiochus; who, with extraordinary pomp, burned it in Seleucia on the sea-coast, erecting on the place a magnificent chapel, called from his surname Nicatorium.

Seleucus was succeeded by his son Antiochus Soter, who reigned nineteen years. He resigned to Antigonus Gonatas all pretensions to the crown of Macedon; and, having engaged in a war with Eumenes king of Pergamus, he was defeated by him, and obliged to yield up part of his dominions. He died in 261 B. C.

Antiochus I. was succeeded by his son Antiochus II., blasphemously surnamed Theos, or the God, who having engaged in a war with Ptolemy Philadelphus, king of Egypt, the Parthians and Bactrians took an opportunity to revolt, and could never afterwards be reduced. In 246 B. C. the God was poisoned by his wife Laodice, whom he had divorced for Berenice daughter to Ptolemy, with whom he made peace on the revolt of the Bactrians. On the death of Ptolemy, Antiochus had divorced Berenice, and took back Laodice; who, to secure herself against the effects of his fickle disposition, poisoned him, and raised to the throne her own son, named Seleucus Callinicus.

Laodice, not thinking herself safe as long as Berenice lived, began immediately to concert measures for putting both her and her son to death. Berenice attempted to save herself by retiring to Daphne, where she shut herself up in an asylum built by Seleucus Nicator. There she was closely besieged by the sons of Seleucus; of which the cities of Asia having intelligence, formed a confederacy in her favor. Her brother the king of Egypt also hastened to her relief with a considerable army; but, before either of these could come to her assistance, both she and her son were barbarously murdered, with all the Egyptians who attended them. Ptolemy, on hearing the melancholy news of his sister's death, determined to take the most severe vengeance on

her murderers. Joining his forces to those of the Asiatics, he carried every thing before him. Having first killed the cruel Laodice, he made himself master of all Syria and Cilicia; then, passing the Euphrates, he subdued all the country as far as Babylon and the Tigris; and had not the progress of his arms been interrupted by a sedition, which obliged him to return to Egypt, it is probable that he would have subdued the whole Syrian empire. As soon as he was returned, Seleucus attempted to revenge himself; but his fleet being destroyed by a violent storm, and his army defeated by Ptolemy, he concluded a truce for ten years. During all this time Arsaces, the prince of Parthia, had established himself so firmly on the throne, that it was in vain to think of dispossessing him. However, as soon as his other affairs would permit, Seleucus undertook an expedition against Arsaces, by whom he was utterly defeated, taken prisoner, and carried into Parthia, where he died four years after. He was succeeded by his eldest son Seleucus III., surnamed Callinicus, or the Thunderer, a weak prince, and was poisoned by two of his officers, when he had reigned one year.

Antiochus, surnamed the Great, brother of Seleucus III., ascended the throne in 225 B. C. In the beginning of his reign two of his generals, Alexander and Molo, rebelled against him. The former had been appointed governor of Persia, and the latter of Media; but they, despising the king's youth, refused to obey. The occasion of this revolt is said to have been their dread of the cruelty of Hermias, the king's prime minister; and as they hoped to draw into their schemes Achæus, governor of Asia Minor, they doubted not of success. In this, however, they failed. Epigenes, the commander of the troops about the king's person, advised him to march without delay against the rebels; but as Hermias reproached him with treachery, and a design to betray him into the hands of his enemies, Antiochus sent two of his generals into the east, while he himself undertook an expedition against Ptolemy Philadelphus, to recover Cœlesyria. In this attempt, however, he was disappointed; and the generals whom he had sent into the east were totally defeated, and their troops cut off; upon which he determined to lay aside his Syrian enterprise, and march in person against the rebels. This was again opposed by Hermias; but, as he found it impossible to alter the king's mind, the treacherous minister found means to get Epigenes, the author of this project, executed, under pretence of holding a correspondence with Molo, one of the rebel chiefs. Antiochus in the mean time pursued his march against the rebels, whom he defeated in a pitched battle; upon which their chiefs killed themselves. On his return he received the submission of the Atropatii, a barbarous people in Media, and put to death his prime minister Hermias, whose treachery he at last discovered. During his life, however, the traitor, by accusing Achæus of treason, had obliged him to revolt in his own defence; so that the king had still two important wars on his hands, viz. that with Ptolemy, king of Egypt, and the other against Achæus. After some deliberation he resolved to march first

against the king of Egypt; and was at first very successful, reducing many cities in Cœlesyria and Palestine, and defeating the Egyptians in a pitched battle; but in 217 B. C., being worsted in the battle of Raphia, he was obliged to abandon all his conquests; of which Ptolemy immediately took possession, and Antiochus was obliged to cede them to him, that he might pursue war against Achæus. Antiochus, having made vast preparations for his expedition, soon reduced Achæus to such distress that he was obliged to shut himself up in the city of Sardis, which he defended for some time with great bravery; till at last, being betrayed by two Cretans, he was delivered up to the king, and by his order put to death. Antiochus then undertook an expedition against the Parthians, whom he obliged to conclude a peace on very advantageous terms. He then turned his arms against the king of Bactria, whom he also compelled to agree to his terms; one of which was, that he should give him up all his elephants. For the confirmation of the treaty, the king of Bactria sent his son to Antiochus; who, being taken with his majestic mien and agreeable conversation, gave him one of his daughters in marriage. He then crossed Mount Caucasus, and entered India; where, having renewed his alliance with Sophagasenus, the king of that country, he received a number of elephants, which increased his stock to 150. See INDIA. From India he marched into Arachosia, Drangiana, and Carmania, establishing order and discipline in all those countries; then, passing through Persia, Babylonia, and Mesopotamia, he returned to Antioch, after an absence of seven years.

In the year 204 B. C. Antiochus made an easy conquest of Judea; but treated the Jews with great kindness and humanity. In the same year he entered into a league with Philip V. of Macedon, on purpose to deprive Ptolemy Epiphanes, the infant king of Egypt, of all his dominions. The Egyptians, however, put the young king under the tuition of the Romans; who immediately required the confederate princes to desist from any enterprise against the king of Egypt, under the penalty of incurring the displeasure of the republic. After delivering this message, M. Æmilius Lepidus, one of the ambassadors, repaired to Egypt, where he took upon himself the office of regent and guardian to the young king. Having regulated affairs there in the best manner he could, he returned to Rome, after having appointed one Aristomenes, an Acarnanian, to be chief minister to the king. Aristomenes, being a man of prudence and fidelity, acquitted himself very well in his new station. Having taken care to recruit his army as well as he could, he sent one Scopas, a man of great authority among the Ætoliens, into that country, to raise auxiliaries. Scopas soon raised an army of 6000 Ætoliens, at that time reputed the best soldiers in the world; and, having joined the Egyptian army, reduced all Judea, put a garrison into the castle at Jerusalem, and on the approach of winter returned to Alexandria, loaded with booty. These exploits, however, were performed when Antiochus was

absent in Asia Minor; and no sooner was he returned than the face of affairs was changed. Scopas was defeated in a pitched battle, where one half of his men were destroyed. He himself escaped to Sidon, where he shut himself up with 10,000 of his soldiers; but, Antiochus having invested the place, Scopas was reduced to the necessity of surrendering at discretion. The king pursued his conquests; recovered all Palestine and Cœlesyria; after which he invaded Asia Minor, in hopes of reducing it also, and restoring the Syrian empire to the same extent it had in the time of Seleucus Nicator. The free cities in Asia Minor immediately had recourse to the Romans, who sent an embassy to Antiochus on the occasion; but, as both parties treated each other haughtily, no satisfaction was given, but every thing tended to an open rupture. While matters were in this situation, Hannibal the Great, being obliged to leave his own country, fled to Antiochus; from whom he met with a gracious reception. As Hannibal had, while a child, sworn perpetual enmity against the Romans, he used all his eloquence to persuade Antiochus to make war with them; and, as the many victories which he had gained over them left no room to doubt of his capacity, Antiochus doubted nothing of being able, by his assistance, to conquer that haughty people. Several embassies passed between the two nations; but chiefly with a design on the part of Antiochus to gain time. Hannibal endeavoured to draw his countrymen into the confederacy against Rome, but without effect. Antiochus, having strengthened himself by several alliances, at last resolved to begin the war in earnest. To consult on the measures proper to be taken, he called a council of war; but excluded from it the only man whose advice he ought to have followed; viz. Hannibal. The reason of this was, that he had become jealous of him from the too great intimacy, as he thought, which he had kept with the Roman ambassadors. However, in this council, it was agreed that the war should be immediately commenced. The king himself was prevailed upon by the Ætoliens to pass over into Greece, and entirely to reject the advice which Hannibal had formerly given, of sending him with an army into Italy. Here he was made generalissimo of the Greek forces; but made none of those efforts that had formerly obtained him the title of Great. Indeed it now plainly appeared, not only that he was incapable of carrying on war against such enemies as the Romans, but even of accepting proper advice when it was given him. In another council in which Hannibal was admitted, that commander advised the king, before he undertook any thing else, to use his utmost endeavours to gain over Philip V. of Macedon; which, he said, was a step so important, that if it could be gained they might, without much ado, become masters of all Greece. But, if Philip could not be prevailed on to make war on the Romans, he was of opinion that the king should send his son Seleucus into Macedon at the head of an army, and thus prevent Philip from giving the Romans any assistance. But he still maintained that the only way to defeat the Romans was to send an army into Italy. This

advice was again rejected; and the king imprudently became the aggressor by falling on a body of 500 Romans before war had been declared. He also made Philip his enemy by entertaining the regent of Athamania, who was a pretender to the crown of Macedonia. To complete all, he himself fell in love, though above fifty years of age, with a beautiful young woman of Chalcis, whom he married; and became so great a slave to this passion that he entirely neglected his affairs; the army gave themselves up to dissipation and debauchery, and every trace of military discipline vanished. In 191 B. C. Antiochus was roused from his lethargy by a declaration of war against him at Rome, and set out for Ætolia. His army at this time amounted to no more than 10,000 foot, and 500 horse. He had been made to believe that he would receive a vast reinforcement in Ætolia; but all the troops he could raise there amounted to only 4000 men. With this force, so exceedingly inadequate to the purpose, he was obliged to oppose the Roman army, who were advancing in conjunction with the Macedonians, and had already made surprising progress. Antiochus seized the straits of Thermopylæ; but was driven from them by the Romans, the king himself being the first that fled. Almost his whole army was destroyed in the battle or in the pursuit, and Antiochus returned with disgrace into Asia.

Soon after his return Antiochus equipped a fleet of 200 sail; on which he immediately embarked for the Thracian Chersonesus, now Crim Tartary, where he fortified the cities of Lysimachia, Sestus, and Abydos, with others in that neighbourhood, to prevent the Romans from crossing the Hellespont. In the mean time Polyxenidas, the Syrian admiral, sent intelligence to the king that the Roman fleet had appeared off Delos; upon which he desired him to seek them out and engage them at all events. He did so, and was defeated with the loss of forty ships taken or sunk in the engagement. This was soon after revenged by the destruction of the Rhodian fleet by the artifice of Polyxenidas; but in the end the king's affairs went every where to wreck. Having laid siege to the city of Pergamus, he was obliged to raise it with loss; the Phœnician fleet commanded by Hannibal was defeated by the Rhodians; and soon after the Syrian fleet under Polyxenidas was utterly defeated by the Romans. Antiochus was so much disheartened, by these repeated defeats, that he appeared like one infatuated. Instead of fortifying more strongly those cities which lay on the frontiers of his kingdom, he entirely deserted them; and thus Lysimachia and Abydos, the two keys to Asia, fell into the hands of the Romans without the least resistance. The arrival of the Romans in Asia, struck Antiochus with such terror, that he instantly sued for peace. The terms he offered were indeed very advantageous, but by no means agreeable to the expectations of the Romans. They therefore gave him this final answer:—1. That, since he had drawn upon himself the war, he should defray the whole expense of it. 2. That he should restore liberty in general to all the Greek cities in Asia: and, 3. That, to prevent future hostilities, he should relinquish all Asia on this side

Mount Taurus. These terms, however, still appeared to him so intolerable that he resolved to continue the war; and determined also to take the most imprudent method of carrying it on, namely, by hazarding all on the event of a general engagement. The king encamped near Magnesia, and strongly fortified his camp. The Romans insulted him in his trenches, and proposed to attack his fortifications, if he continued to decline an engagement. At last the king, thinking it would be shameful for him longer to refuse an engagement, fought a battle, which issued in his entire defeat. No fewer than 50,000 foot, and 4000 horse were killed; 1500 were taken prisoners, and fifteen elephants. In the consular army there were but 300 foot killed, and twenty-five horse.

Antiochus retired to Sardis with as many of his forces that had escaped the slaughter as he could draw together. From Sardis he soon marched to rejoin his son Seleucus, who had fled to Apamea. As for the consul, he took advantage of the king's defeat and flight, making himself master of all the neighbouring countries. Deputies hastened to him from all parts; the cities of Thyatira, Magnesia, Trallis, Magnesia in Caria, all Lydia, and Ephesus itself, though highly favored by Antiochus, declared for the Romans. Polyxenidas, upon the news of the king's defeat, left the port of Ephesus, and sailed to Patara, where he landed with a very small guard, and returned by land into Syria. The consul took the road to Sardis, which opened its gates to him. Antiochus, finding his affairs in a bad situation both by sea and land, hastened to conclude a peace, which he obtained on the following terms:—He was to confine his dominions within Mount Taurus; to pay 15,000 Euboic talents for the expenses of the war; to deliver up Hannibal and some other foreigners who were obnoxious to the Romans. For the fulfilment of these articles he gave seventy hostages, one of whom was his youngest son Antiochus. The peace being ratified by the Sarati, the Greek cities were by the Romans restored to their liberty, the provinces of Caria and Lydia given to the Rhodians, and all the rest that had belonged to Antiochus on that side of Mount Taurus bestowed upon Eumenes.

Antiochus did not long survive his misfortune at Magnesia. Some tell us, that, being greatly puzzled how to raise the sum he had engaged to pay to the Romans, he seized on the riches which had for many ages been deposited in a temple of Jupiter Belus in the province of Elymais; upon which the populace rose in arms, and slew him and all his attendants. Others inform us that he was killed at an entertainment by one of his guests. Antiochus the Great died in 187, and with him the glory of the Syrian empire.

Antiochus the Great was succeeded by his son Seleucus IV., surnamed Philopator, A. A. C. 187, who reigned only twelve years, dying in 175, and leaving the Syrian throne to his son, or his brother according to Alstidius, Antiochus IV., surnamed Epiphanes, the most barbarous and bloody tyrant that ever reigned in Syria. The Romans now gave laws to the kings of Syria; insomuch that, when Antiochus Epiphanes hesitated at obeying the commands of the

senate; one of the ambassadors drew a circle round him with a rod on the floor, and told him he should not go out of that spot before he had told him what he was to do. But the most horrible transactions of this prince are his wars with the Jews, and persecutions of them; of which a full account is given under the article **Jews**.

After the miserably death of the monster Epiphanes, at Tabæ, the Syrian throne fell a prey to a series of tyrants, impostors, and usurpers, of whom it is sufficient to give the following brief chronological list: Antiochus V., surnamed Eupator, succeeded his wicked father in 164; but reigned only two years. He was succeeded in 162 by Demetrius I., surnamed Soter, a brother of Antiochus Epiphanes, who had only reigned eleven years, when, in 151, the crown was claimed by Alexander Balas an impostor, who pretended to be a son of Epiphanes; and being supported in this false claim by Ptolemy Philometer, king of Egypt, by the kings of Pergamus and Cappadocia, and by the Romans, defeated and killed Demetrius, and reigned five years, some say six; but was at last killed in Arabia, A. A. C. 146. See **ALEXANDER BALAS**. Demetrius II., surnamed Nicator, the lawful heir, being the son of Demetrius I., then succeeded; but he being taken prisoner two years after by the Parthians, in 144, the throne was seized by Antiochus VI., surnamed Enthous, who reigned two years along with a usurper named Diodotus Tryphon, who afterwards assumed the sole power for other three years, till A. A. C. 139, when he was expelled by Antiochus VII., surnamed Zidetes, and also Pius and Soter, the son of Demetrius I., and brother of Demetrius II., who reigned ten years. But Demetrius II., being now liberated by the Parthians, was restored to his kingdom; but had reigned only three years, when Alexander Zebina, a new impostor, who pretended to be the son of the impostor Alexander Balas, being assisted and supported by Ptolemy Physcon, the tyrant of Egypt, expelled Demetrius a second time in 126, and reigned three years. In 123, however, the usurper Zebina was justly dethroned and killed by Antiochus VIII., surnamed Grypus, the son of Demetrius II. See **ALEXANDER ZEBINA**. Grypus reigned twenty-nine years in all; but, in his ninth year, his brother Antiochus Cyzicenus rebelled against him, and in his eleventh, A. A. C. 112, erected Cœlesyria into a separate kingdom, wherein he reigned for eighteen years, and hence is ranked as Antiochus IX. by chronologists. On the death of these two brothers, A. A. C. 94 and 93, Seleucus V., a third son of Antiochus VIII., claimed the crown of Syria, but was opposed by four other pretenders, viz. Antonius Eusebes, Philip, Demetrius III. surnamed Eucerus, and Antiochus X. surnamed Pius, all claiming as descendants of the royal house of the Seleucidæ. These claimants involved the country in a civil war for six years; when Philip, overcoming them all, reigned two years alone. But Aretas seized Cœlesyria in 85; and, two years thereafter, Tigranes king of Armenia, taking advantage of the dissensions of the Seleucidæ, and being invited by a party of the Syrians themselves, reduced the whole country in 83, and governed it for

eighteen years with more tranquillity than it had enjoyed for a long period. Antiochus XI., however, surnamed Asiaticus, or the XIII. as he is styled by some (for there were other two usurpers of the name), the son of Cyzicenus, who had been skulking in Cilicia, claimed the crown, in A. A. C. 69, and was supported against Tigranes by Lucullus the Roman general, who defeated Tigranes, and declared Antiochus king of Syria. But his reign was short, only four years: for Tigranes, attempting to recover the kingdom, was defeated by Pompey the Great, who, disregarding Antiochus's claim, reduced the whole kingdom to a Roman province, A. U. C. 691, and A. A. C. 65.

From being a province of the Roman republic, Syria became, on the division of the Roman empire, subject to the emperors of the East; but in A. D. 634 it was invaded by the Saracens, who completed the conquest of it in 640, when it was confirmed to them by the treaty made with Constantine IV. See **CONSTANTINOPLE**, and **SARACENS**.

In A. D. 970 Syria was conquered by the Fatemite Khalifs, soon after their conquest of Egypt. See **EGYPT**. But the emirs of Damascus revolted in 1067; and those of Aleppo in 1068. In 1096 the crusades from Europe commenced; and the Christians conquered that part of Syria called the Holy Land, which they kept possession of for above 100 years. See **CRUSADES**. In 1166 Nureddin, or Nuroddin, emir of Damascus, defeated the Egyptians, and conquered the greatest part of Syria; and his nephew, the famous Saladin, soon after, on the death of the khalif Aded, seized the government of Egypt, put an end to the power of the Fatemites, and erected a new dynasty. See **EGYPT**. But in 1259 all Syria was over-run and conquered by the Tartars under Hulaku.

The Tartars did not long retain possession of Syria. It was soon recovered by the sultans of Egypt; who also, in 1291, totally expelled the Christian crusaders. Syria was again over-run and ravaged by Tamerlane in 1400; but he did not attempt to retain it. After this period it underwent the revolutions of Egypt, till both were conquered by the Turks under Selim I. in 1517. See **EGYPT**.

Ever since the above conquest, by Selim, this country continued in the undisturbed possession of the Turks, till the invasion of Egypt by the French in 1798. Soon after that event Buona-parte over-ran Syria, and took Gaza and Jaffa, or Joppa, &c.; but found a fatal stop put to his victorious career by British valor, at Acre, or St. Jean D'Acre, the ancient Ptolemais; where the brave Sir Sidney Smith gained immortal fame by the defence of that small town.

The present state of Syria differs little from that of the rest of Asiatic Turkey. Its open plains, separated by no defined boundary from Arabia, Persia, and Asia Minor, are variously occupied by wandering tribes of Turks and Greeks, who form, as elsewhere, the basis of the population. The only tribes which can be considered as appropriate to Syria are the tenants of the heights of Lebanon, the most remarkable of which are the Druses and Maronites.

SYRINGA, the lilac, or pipe tree, in botany, a genus of plants belonging to the class of *dianthia*, and order of *monogynia*; and in the natural system ranking under the forty-fourth order, *sepiariæ*. The corolla is quadrifid, and the capsule is bilocular. There are three species, viz. 1. *S. Persica*, the Persian lilac, is a native of Persia. It has lanceolate leaves, and was cultivated in Britain in the middle of the seventeenth century, about 1658, or earlier. 2. *S. suspensa*, the hanging lilac, is a native of Japan. 3. *S. vulgaris*, the common lilac, is originally a native of Persia. It is distinguished by oval heart-shaped leaves, and was cultivated in Britain about 1597 by Mr. John Gerard.

SYRINGE, *n. s. & v. a.* Gr. *συριγγή*. A pipe through which any liquor is squirted: to spout by a syringe.

The heart seems not designed to be the fountain or conservatory of the vital flame, but as a machine to receive the blood from the veins, and force it out by the arteries through the whole body, as a *syringe* doth any liquor, though not by the same artifice.

Ray.

A flux of blood from the nose, mouth, and eye, was stopt by the *syringing* up of oxycrate.

Wiseman's Surgery.

The SYRINGE is a well-known instrument, serving to imbibe or suck in a quantity of fluid, and to squirt or expel the same with violence. It is formed from the Greek *συριγγή*, or the Latin *syrinx*, a pipe. A syringe is only a single pump, and the water ascends in it on the same principle as in the common sucking pump. See *HYDROSTATICS*.

SYRINGOIDES LAPIS, a fossil stone.

SYRINX (Gr. *συριγγή*, a pipe), in mythological painting and sculpture, a nymph of Arcadia, daughter of the river Ladon. Pan became enamoured of her and attempted to offer her violence; but Syrinx escaped, and at her own request was changed by the gods into a reed, called *syrinx* by the Greeks. The god made himself a pipe with the reeds into which his favorite nymph had been changed, and upon this pipe he is often introduced playing, in pictures. The *syrinx*, or Pan's pipe, is frequently found figured upon ancient monuments. It is composed of seven tubes of unequal size. Ordinarily it is placed in the hands of fauns and satyrs (the followers of Pan); but is sometimes also the accompaniment of rustics. Upon the sarcophagus of Tyrrania, preserved in the Museum at Arles, and of which a description and engraving are included in the second volume of Millin's *Monumens Antiques Inédits* (plate 37) is depicted a *syrinx* in a case or box. It is occasionally found on the earlier Christ monuments as an emblem of our holy faith; the divine founder of Christianity having been regarded as the shepherd of his spiritual flock, and the *syrinx* being the common musical instrument of the husbandman or shepherd.

SYRMA (Gr. *συνμα*, the train of a gown, from *σύνω*, to drag along), in archæology, a very long tunic descending even to the heels, but which nevertheless had not an amplitude greater than the thickness of the body.

SYRNA, the wife of Podalirius, the son of Æsculapius.

SYRNA, an ancient town of Caria, built by Podalirius, where he was afterwards worshipped.

SYRO-GRECIAN (from Syria and Grecian), an epithet applied to the empire of the Seleucidæ in Syria, being founded by the Greeks in Syria. See *SYRIA*.

SYRO-GRECIANS, the people of Syria, under the Seleucidæ, being a mixture of Greeks and Syrians.

SYRO-MACEDONIAN (from Syria and Macedonia), a word synonymous with *Syro-Greæcian*.

SYRO-MACEDONIAN ERA. See *SELEUCIDÆ*.

SYRO-PHœNICIA, a country lying between Syria and Phœnicia, inhabited, according to Borchart, by natives of both nations mixed.

SYROS, in ancient geography, an island in the Ægean Sea, one of the Cyclades; about twenty miles in circumference, and very fertile in corn, wine, and fruits. The climate is mild, and the inhabitants long-lived. *Hom. Od. xv. 504. Strabo 10.*

SYROS, a town of Caria. *Paus. iii. c. 26.*

SYRTES, in ancient geography, two large sand-banks in the Mediterranean, on the coast of Africa; the one near *Leptis*, the other near *Carthage*. As they often shifted, and were sometimes very high, sometimes very low under water, they were very dangerous, and often fatal to ships. *Mela i. c. 7. ii. c. 7.*

SYRTICA REGIO, the SYRTIC REGION, a country of Africa, one of the three great divisions of ancient Libya. It comprehended the coast of Barbary between Tripoli and Barca; and was so named from

SYRTIS, an island and a spacious gulf of Africa, on the coast of Barbary, between the above limits; now called *Sidra*. The quicksands in the gulf shifted, whence the word was used as an appellative.

SYRTIS, *n. s.* Lat. *syrtis*. A quicksand; a bog.

A boggy *syrtis*, neither sea, nor good dry land.

Milton.

SYRUS, in fabulous history, the son of Apollo by the nymph *Sinope*. See *SINOPE*. He is fabled to have given his name to Syria. *Plut. in Luc.*

SYRUS (Publius), a Syrian mimic poet, who flourished about forty-four years B. C. He was originally a slave sold to a Roman patrician called *Domitius*, who brought him up with great attention, and gave him his freedom when of age. He gained the esteem of the most powerful men at Rome, and reckoned *J. Cæsar* among his patrons. He soon eclipsed the poet *Laberius*, whose burlesque compositions were in general esteem. There remains of *Syrus* a collection of moral sentences, written in iambics, and placed in alphabetical order.

SYSIGAMBIS, or SISYGAMBIS, the mother of *Darius III.* king of Persia. She was so very kindly treated by *Alexander the Great*, that, though she had been able to survive the death of her son, and the overthrow of his empire, she could not survive that of *Alexander*, but killed herself when he died. See *MACEDON*.

SYSSARCOSIS, in anatomy (from *σύν*, with, and *σαρκος*, flesh), a kind of articulation by the intervention of flesh. *Ash.*

SYSTEM, *n. s.*

SYSTEMATICAL, *adj.*

SYSTEMATICALLY, *adv.*

of things together; a scheme which unites many things in order or mutual dependence: the adjective and adverb corresponding.

I treat of the usefulness of writing books of essay, in comparison of that of writing *systematically*.

Boyle.

He presently bought a *system* of divinity, with design to apply himself straightway to that study.

Fell.

It will be necessary, in a discourse about the formation of the world, to give you a brief account of some of the most principal and *systematical* phenomena that occur in it.

Bentley.

The best way to learn any science is to begin with a regular *system*, or a short and plain scheme of that science well drawn up into a narrow compass.

Watts.

Now we deal much in essays, and unreasonably despise *systematical* learning; whereas our fathers had a just value for regularity and *systems*.

Id.

Aristotle brings morality into *system*, by treating of happiness under heads, and ranges it in classes according to its different objects, distinguishing virtues into their several kinds, which had not been handled *systematically* before.

Baker.

SYSTEM, in general (from *συστημα*, composition,) denotes a chain of principles and conclusions, or the whole of any doctrine, the several parts whereof are bound together, and depend on each other.

SYSTEM, in music, an assemblage of the rules for harmony, deduced from some common principle by which they are reunited; by which their connexion one with another is formed; whence, as from their genuine source, they natively flow; and to which, if we would account for them, we must have recourse.

SYSTOLE, *n. s.* Fr. *systole*; Gr. *συστολη*. In anatomy. The contraction of the heart.

The *systole* resembles the forcible bending of a spring, and the diastole its flying out again to its natural site.

Ray.

SYSTOLE, in anatomy, is the opposite state to the diastole, or dilatation of the heart. See ANATOMY.

SYSTYLE, in architecture, that manner of placing columns where the space between the two shafts consists of two diameters, or four modules. See ARCHITECTURE.

SYTHIAS, a river of Peloponnesus, running through Sicyonia, into the bay of Corinth. *Paus.* ii. 7.

SYXHANDEMAN (Sax.), a man of the middle rank, under the Anglo-Saxon government: a man worth 600 shillings. *Ash.*

SYZYGIA, or SYZYGY (from *συσζυγία*, conjunction), in astronomy, a term equally used for the conjunction and opposition of a planet with the sun. The word is formed from the Greek *συσζυγία*, which properly signifies conjunctio. On the phenomena and circumstances of the syzygies a great part of the lunar theory depends. See ASTRONOMY.

SZEGEDIN, a large town of East Hungary, in the county of Csongrad, opposite to the confluence of the rivers Theyss and Maros. It is surrounded by a mound and moat, and has a brick fort erected by the Turks in the sixteenth century. This is one of the principal towns of Hungary, containing manufactures of woollens, leather, and toys, on a small scale, but all of importance in a country where manufactures are in their infancy. Its commercial intercourse is considerable. The inhabitants possess a number of barges, some of the size of 200 or 250 tons, with which they navigate not only the Maros and the Theyss, but the Danube: their exports consisting chiefly of the products of the adjacent country, viz. corn, cattle, wool, tobacco, and timber. Cotton they import from Turkey, and make the object of a transit trade: salt from Transylvania. The tobacco raised in this neighbourhood is in good repute. As to religion, the Catholics and the followers of the Greek church predominate. Here is a monastery of Minorites; a school taught by the Piarist monks; a gymnasium or classical school; and a small philosophical seminary. Other public buildings are several hospitals, a work-house, and theatre. This town fell, in the beginning of the sixteenth century, into the hands of the Turks, and continued in their possession above a century and a half, being retaken by the Austrians only in 1686, some time after the route of the Turkish army by Sobieski. Population 26,000. 100 miles S. S. E. of Pest, and thirty north of Csongrad.

SZOLNOK, Belso or Inner, a palatinate of Transylvania, bordering on Hungary on the north, and the district of Nosserland on the east, having a territorial extent of 1335 square miles, with about 110,000 inhabitants.

SZOLNOK, Koscep or Middle, a palatinate of Transylvania, bounded by Hungary entirely on the north, and partly on the west. Its area is 835 square miles, and its population 50,000.

T.

T is used, 1. as a letter; 2. as an abbreviation; 3. as a word; and 4. it was anciently used as a numeral. I. As a letter, T, or t, is the nineteenth of our alphabet, and the fifteenth consonant. The sound is formed by a strong expulsion of the breath through the mouth, upon a sudden drawing back of the tongue from the fore part of the palate, with the lips at the same time open. The proper sound of *t* is expressed in most words

beginning or ending with that letter, as in take, tell, hot, put. *Ti* before a vowel has the sound of *si*, or rather of *shi*, as in creation, except when *s* precedes, as in question; and in derivatives from words ending in *ty*, as mighty, mightier. Anciently this syllable *ti* was considered as distinct from the vowel that followed it, and such words as na-ti-on, sta-ti-on, &c., formed trisyllables in poetry, as appears from the version of

the Psalms still used in our churches. But now, in modern improved English, *ti* is not considered as a distinct syllable, but only as softening the *t* to the sound of *sh*, as if the words were spelt *na-shon*, *sta-shon*, &c. *Th* has two sounds; the one hard, as thou, father; the other soft, as thing, think. The sound is hard in these words, the, then, than, there, with their derivatives and compounds; and in the words that, this, thus, thy, they; and in all words in which *th* comes between two vowels, as whether, rather; and between *r* and a vowel, as burthen: but it is soft in thane, thank, thatch, thaw, theatre, theft, thence, theocracy, and all other derivatives of ΘΕΟΣ, theorem, theory, thesis, and all other words of Greek derivation, thick, thief, thigh, thin, third, thirst, thistle, though, thong, thorn, thorough, thought, thousand, thrall, thrash, thread, threat, three, thrice, thrift, thrive, throat, throne, throng, through, throw, thrumb, thrush, thrust, thump, thunder, thursday, thwack, thwart, &c., and all their compounds and derivatives. But in the word thither, and its compounds, *th* sounds soft in the first syllable and hard in the second; and in thyme the *h* is not sounded. II. As an abbreviation *T* was used among the Roman writers for Titus, Titulus, &c.; Tab. for Tabularius; Tab. P. H. C. Tabularius Provinciae Hispaniae Citerioris; Tar. Tarquinius; Ti. Tiberius; Ti. F. Tiberii filius; Ti. L. Tiberii libertus; Ti. N. Tiberii Nepos; T. J. A. V. P. V. D. tempore judicem arbitrumve postulat ut det; T. M. P. terminum posuit; T. M. D. D. terminum dedicavit; Tr. trans. tribunus; Tr. M. or Mil. tribunus militum; TR. PL. DES. tribunus plebis designatus; TR. AER. tribunus ærarii; TRV. CAP. triumviri capitales; T. P. or TRIB. POT. tribunicia potestate; Tul. H. Tullus Hostilius. In music *T* stands for tutti, all or altogether. III. As a word it is used without a vowel, both in surgery and mechanics. IV. As a numeral *T* was used among the ancients for one hundred and sixty; and with a dash at top, thus \bar{T} , it signified one hundred and sixty thousand.

T, *adj.*, is used as a distinction for a peculiar kind of bandage in surgery.

T, *n. s.* *T* SQUARE, or *TEE* SQUARE, in drawing and mechanics, an instrument so named from its resemblance to a capital *T*.

TAANATH-SHILOH, a town of Israel, in Ephraim, ten miles east of Shechem. It existed under the name of Thenath as late as A. D. 400.

TAAAS, or TAAES, a considerable city of Yemen, in Arabia, between Mocha and Sana, forty-eight miles from Mocha. It is surrounded by mountains, which are said to be very productive of plants. They are in the possession of several sheiks, who are independent of, and even hostile to the Imam, and Niebuhr was not allowed to make any excursions among them. The city is described by Sir Henry Middleton as about half the size of Sana.

TAAUT, TAAUTES, TAAUTOS, TAAUTUS, or THOTH, a Phœnician deity, the same with Hermes of Egypt, and Mercury of the Greeks and Romans. See HERMES, MERCURY, MYSTERIES, POLYTHEISM, and THOTH. But Mr. Lempriere makes him the same with Saturn, for which he quotes Varro.

TAB, the ancient Arosis, a river of Persia which rises in the mountains of Pars, divides that province from Klusistan, and falls into the Persian gulf near Endian. At that place it is eighty yards wide, and navigable for boats of twenty tons.

TABAGO, or TABOGA, a mountainous island in the Pacific, near the coast of Mexico, about three miles long and two broad. On the north side the high land declines with a gentle descent, and near the strand the soil is a black mould, and deep. This side of the island makes a very pleasant appearance, and seems to be a garden of fruit trees. The principal products are plantains and bananas. There was formerly a small town here near the sea, but it was ruined by privateers. Before it is a good road, about a mile from the shore, where ships may ride very safely in sixteen or eighteen fathom water. Eighteen miles south of Panama.

TABANUS, the breeze-fly, a genus of insects belonging to the order of diptera. The mouth is extended in a fleshy proboscis, terminated by two lips. The rostrum is furnished with two pointed palpi placed on each side of the proboscis, and parallel to it. Gmelin has enumerated thirty-eight species; of which three only are found in Great Britain; viz. 1. *T. bovinus*, or great horse fly, has a gray head; the eyes almost of a black brown, occupying the greatest part of it. The thorax is of a gray color; the abdomen is yellowish, with a triangular white spot on the middle of every ring, which constitutes a longitudinal band of spots, the point of which is directed towards the thorax. The thighs are blackish, and the legs yellow. The wings are dusky, with brown veins of a deeper dye. This insect is the terror of horned cattle, horses, &c. Its mouth is armed with two sharp hooks which penetrate their hide; while with its proboscis, which is shaped like a sting, it sucks their blood, of which it is very greedy. The puncture of the tabanus is keen and painful. The insect is very common in damp woods and meadows, especially during the great heats, when it is most troublesome. The horned cattle are sometimes so molested by their stings that they go mad, run down precipices, tear themselves on the stumps of trees, stones, &c. 2. *T. concutiens* has a brown head; eyes green and brown, with black spots; the thorax brown with black spots; the abdomen above, yellow with triangular brown spots; yellow legs, and white wings with black and brown spots. The length is four lines and a half. 3. *T. pluviatilis* is of an ashen gray color; its eyes are green, with brown streaks. The thorax is brown, marked with about seven longitudinal gray lines; the wings, which are brown and ash-colored, are dotted over with small white spots, and have a black spot on the margin; the legs are surrounded with brown and white rings alternately. This species is very common in meadows, and is about four lines in length.

TABARCA NEUVA, a small island of Spain, in the Mediterranean, on the coast of Valencia. It is almost destitute of trees and water, but is inhabited by the descendants of a colony of Spaniards, who were, in 1771, redeemed from

slavery in Barbary by the government, and settled here.

TABASCO, an island, or rather neck of land, in the south-west part of the gulf of Mexico, at the bottom of the gulf of Campeachy, on which is built the town of Tabasco. It is about thirty-six miles in length, and seven or eight broad. Near it, on the continent, are great plains abounding in cattle, sheep, &c., and a wild animal called the mountain cow, or tapir, which subsists on moss. It is separated from the continent by the river.

TABASCO RIVER, a river of North America, which runs into the bay of Campeachy, long. 93° 40' W., lat. 18° 15' N.

TABASHEER, a Persian word, signifying a hard substance found in the cavities of the bamboo or Indian reed, and highly valued as a medicine in the East Indies. From the experiments of Dr. Russel it appears that the tabasheer is the juice of the bamboo thickened and hardened. Its medical effects are mentioned in a Persian work of Mahommed Monein Hosemy, by Mr. Williams, a surgeon in the East Indies. It is useful in bilious vomitings, the bloody flux, palpitations of the heart, faintings, cases of debility from heat; also in the piles, acute burning fevers, pustules in the mouth, thrush; and, with oxymel, is of great service against restlessness, melancholy, and hypochondriacal affections. The habitual internal use of it is prejudicial to the virile powers, and to the lungs. Its correctives are the gum of the pine and honey.

TABBY, *n. s.* Fr. *tabis*; Ital. *tabi*, *tabino*. A kind of waved silk: hence a striped appearance of any other kind.

A *tabby* cat sat in the chimney-corner. Addison.

On her *tabby* rival's face
She deep will mark her new disgrace. Prior.

Brocades, and *tabies*, and gauses. Swift.

TABBYING, a passing the silk or stuff under a calendar, the rolls of which are made of iron or copper variously engraven, which, bearing unequally on the stuff, renders the surface thereof unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABEFY, *v. n.* Lat. *tabefacio*. To waste; to extenuate.

Meat eaten in greater quantity than is convenient *tabefies* the body. Harvey on Consumptions.

TABELLARIÆ LEGES, in Roman antiquity, laws made by suffrages delivered upon tabellæ, tablets, and not viva voce. There were four of them, viz. the Gabinian, by Gabinus, A. U. C. 614; the Cassian, by Cassius, A. U. C. 616; the Papirian, by Papirius Carbo, A. U. C. 622; and the Cælian, by Cælius, A. U. C. 646.—Cic. de Legg. iii. c. 16.

TABELLIO, in the Roman law, an officer or scrivener, much the same with our notaries public, who are often called tabelliones.

TABERNACLE, *n. s.* & *v. n.* Fr. *tabernacle*; Lat. *tabernaculum*. A temporary habitation; casual dwelling: to house; enshrine.

The word was made flesh, and *tabernacled* amongst us, and we beheld his glory. John i. 14.

They sudden reared
Cælestial tabernacles, where they slept
Fann'd with cool winds. Milton's *Paradise Lost*.

The greatest conqueror did not only compose his divine odes, but set them to music: his works, though consecrated to the *tabernacle*, became the national entertainment, as well as the devotion of his people. Addison.

The **TABERNACLE**, under the Hebrew theocracy, was a kind of building in the form of a tent, set up, by command of God, for the performance of religious worship, sacrifices, &c., during the journeying of the Israelites in the wilderness; and, after their settlement in Canaan, used for the same purpose till the building of the temple. It was divided into two parts; the one covered, and properly called the tabernacle; and the other open, called the court.—See Exodus xxv.—xxvii.

TABERNACLES, FEAST OF, a solemn festival of the Hebrews, observed after harvest, on the fifteenth day of the month Tisri, instituted to commemorate the goodness of God, who protected the Israelites in the wilderness, and made them dwell in booths when they came out of Egypt. On the first day of the feast they began to erect booths of the boughs of trees, and in these they continued seven days. The booths were placed in the open air, and were not covered with cloths, nor made too close by the thickness of the boughs; but so loose that the sun and the stars might be seen, and the rain descend through them. For further particulars see Leviticus xxiii.

TABERNÆ, in Roman antiquity, were houses made of boards, shops, or warehouses. Such shops set up in conquered countries gave rise to towns; as, 1. T. Rhenanæ, a town of Germany, at the conflux of the Rhine and the Felbach; now called Rhine-Zabern. 2. T. Riguæ, a town of ancient Gaul, on the Moselle; now called Bern Castle. 3. T. Tres. See **TABERNE**. 4. T. Tribocorum, a town of Gaul, in the ci-devant province of Lower Alsace, now in the department of the Lower Rhine, called Saverne. See SAVERNE.

TABERNÆMONTANA, in botany, a genus of plants belonging to the class of pentandria, and order of monogynia; and in the natural system arranged under the thirtieth order, contortæ. There are two horizontal folioles, and the seeds are immersed in pulp. There are eight species, all foreign plants.

TABID, *adj.* Fr. *tabide*; Lat. *tabidus*. Wasted by disease; consumptive.

The *tabid* disposition, or the ulcer or ulcers of the lungs, which are the foundation of this disease, is very different from a diminution of the body, and decay of strength from a mere relaxation.

Blackmore.

In *tabid* persons milk is the best restorative, being chyle already prepared. Arbuthnot on Aliments.

TA'BLE, <i>n. s., v. n., & v. a.</i>	} French <i>table</i> ; Latin <i>tabula</i> . Any flat or level surface, for ex- hibition or otherwise; a picture; sy- nopsis; index;
TA'BLEBOOK, <i>n. s.</i>	
TA'BLECLOTH,	
TA'BLEMAN,	
TA'BLETALK,	
TAB'LET,	
TAB'ULAR, <i>adj.</i>	
TAB'ULATED.	

a raised surface or board at which meals are partaken: hence an entertainment; persons sitting at table: the palm of the hand: to table is to board; live at the table: also to note down in a table or catalogue: 'to turn the tables' is to change the condition or fortune entirely: the compounds are of obvious meaning: tablet is a diminutive of table; also a medicine in a square form: tabular is set down in tables; laminated: tabulated, flat of surface.

Upon the castle hill there is a bagnio paved with fair tables of marble. *Sandys.*

He was the writer of them in the tables of their hearts. *Hooker.*

Give me some wine, fill full,
I drink to the general joy of the whole table. *Shakspeare.*

What might you think,
If I had played the desk or table-book? *Id. Hamlet.*

I never loved myself,
Till now, infixed, I beheld myself
Drawn in the flattering table of her eye. *Shakspeare.*

We may again
Give to our tables meat, sleep to our nights. *Id.*

I could have looked on him without admiration,
though the catalogue of his endowments had been
tabled by his side, and I to peruse him by items. *Id. Cymbeline.*

Monsieur the nice,
When he plays at tables, chides the dice. *Shakspeare.*

Let me praise you while I have a stomach,
—No, let it serve for table-talk. *Id. Merchant of Venice.*

It hath been anciently in use to wear tablets of arsenick, or preservatives against the plague; as they draw the venom to them from the spirits. *Bacon.*

In clericals the keys are lined, and in college they use to line the tablemen. *Id. Natural History.*

I will end with Odo holding master doctor's mule,
and Anne with her tablecloth. *Camden's Remains.*

All these true notes of immortality
In our heart's table we shall written find. *Davies.*

I have no images of ancestors
Wanting an ear or nose; no forged tables
Of long descents, to boast false honors from. *Ben Jonson.*

Mistress of a fairer table
Hath not history nor fable. *Id.*

His Jalyus or Bacchus he so esteemed, that he had rather lose all his father's images than that table. *Peacham.*

We are in the world like men playing at tables,
the chance is not in our power, but to play it, is; and when it is fallen, we must manage it as we can. *Taylor.*

Nature wipes clean the table-book first, and then pourtrays upon it what she pleaseth. *More against Atheism.*

You will have no notion of delicacies, if you table with them; they are all for rank and foul feeding. *Felton.*

If there is nothing else to discourage us, we may safely come to the Lord's table, and expect to be kindly entertained by him when we do. *Kettlewell.*

If it be thus, the tables would be turned upon me; but I should only fail in my vain attempt. *Dryden.*

Put into your table-book whatsoever you judge worthy. *Id.*

His fate makes table-talk, divulged with scorn,
And he a jest into his grave is born. *Id. Juvenal.*

I prepared to pay, in verses rude,
A most detested act of ingratitude:
Ev'n this had been your elegy which now
Is offered for your health, the table of my vow. *Dryden.*

It was by the authority of Alexander, that through all Greece the young gentlemen learned before all other things, to design upon tablets of boxen wood. *Id.*

They that are honest would be arrant knaves if the tables were turned. *L'Estrange.*

Children at a table never asked for any thing, but contentedly took what was given them. *Locke on Education.*

It might seem impertinent to have added a table to a book of so small a volume, and which seems to be itself but a table: but it may prove advantageous at once to learn the whole culture of any plant. *Evelyn's Kalendar.*

Nor hath the fruit in it any core or kernel; and differing from other apples, yet is a good table fruit. *Mortimer.*

Many of the best diamonds are pointed with six angles, and some tabulated or plain, and square. *Grew's Museum.*

He improves by the table-talk, and repeats in the kitchen what he learns in the parlour. *Guardian.*

This shuts them out from all table conversation and the most agreeable intercourses. *Addison's Spectator.*

Among the Romans, the judge or prætor granted administration, not only according to the tables of the testament, but even contrary to those tables. *Ayliffe's Parergon.*

The pillared marble, and the tablet brass,
Mouldering, drop the victor's praise. *Prior.*

All the nodules that consist of one uniform substance were formed from a point, as the crusted ones, nay, and most of the spotted ones, and indeed all whatever except those that are tabular and plated. *Woodward on Fossils.*

No fair adversary would urge loose table-talk in controversy, and build serious inferences upon what was spoken but in jest. *Aterbury.*

There are books extant which the atheist must allow of as proper evidence; even the mighty volumes of visible nature, and the everlasting tables of right reason; wherein, if they do not wilfully shut their eyes, they may read their own folly written by the finger of God in a much plainer and more terrible sentence than Belshazzar's was by the hand upon the wall. *Bentley's Sermons.*

The nymph the table spread,
Ambrosial cates, with nectar rosy red. *Pope.*

Nature's fair table-book, our tender souls,
We scrawl all o'er with old and empty rules
Stale memorandums of the schools. *Swift's Miscellany.*

A TABLE is a moveable piece of furniture, usually made of wood or stone, and supported on pillars or feet, for the reception of things placed on it.

TABLE, in mathematics, a system of numbers calculated to be ready at hand for expediting astronomical, geometrical, and other operations.

TABLES, LAWS OF THE TWELVE, were the first set of laws of the Romans; thus called either because the Romans then wrote with a style on thin wooden tablets covered with wax; or rather because they were engraved on tables or plates of copper, to be exposed in the most noted part of the public forum. After the expulsion of the kings, as the Romans had no fixed system of

law ample enough to take in the various cases that might occur, they resolved to adopt the best laws of the Greeks. One Hermodorus was appointed to translate them, and the decemviri arranged them in ten tables. After much care they were enacted and confirmed by the senate and people, A. U. C. 303. In 304 they found something wanting, which they supplied from the laws of the kings, and from certain customs which use had authorised; all these being engraven on two other tables made the law of the twelve tables so famous in the Roman jurisprudence, the source of the civil or Roman law.

TABLES OF THE LAW, in Jewish antiquity, two tables on which was written the decalogue, or ten commandments, given by God to Moses on mount Sinai.

TABLE MOUNTAIN, a mountain of the CAPE OF GOOD HOPE colony, which see.—Also a mountain of the United States, in Pendleton district, South Carolina, near the north-west border of the state, 3168 feet higher than the surrounding country, and about 4000 above the level of the sea. It presents on one side a tremendous precipice of solid rock, about 900 feet nearly perpendicular.

TABOR, *n. s. & v. n.* } Old Fr. *tabourin*,
TABOER, *n. s.* } *tabour*. A small
TABORET, } drum; a drum beaten
TABORINE, } with one stick to ac-
TABBERE, } company a pipe: to
TABRET. } strike as on a tabor
 or lightly: taborer and taberere are names of the player on this instrument: taboret and taborine, small kinds of tabors.

Wherefore didst thou steal away, that I might have sent thee away with mirth and with *tabret*?

Gen. xxxi. 27.

And her maids shall lead her as with the voice of doves, *tabouring* upon their breasts.

Nah. ii. 7.

I saw a shole of shepherds outgo,

Before them yode a lusty *taberere*,

That to the merry hornpipe plaid,

Whereto they danced.

Spenser's Pastorals.

Would I could see this *tabourer*.

Shakspeare.

Trumpeters,

With brazen din blast you the city's ear,

Make mingle with our rattling *tabourines*,

That heaven and earth may strike their sounds together,

Applauding our approach.

Id. Antony and Cleopatra.

If you did but hear the pedlar at the door, you would never dance again after a *tabour* and pipe.

Id. Winter's Tale.

Some blow the bagpipe up, that plays the country round:

The *tabour* and the pipe some take delight to sound.

Drayton.

Morris dancers danced a maid marian, and a *tabour* and pipe.

Temple.

They shall depart the manor before him with trumpets, *tabourets*, and other minstrels.

Spectator.

TABOR, in ancient geography, a mountain of Galilee, near Kadesh, about twelve miles from Tiberias. It has the form of a sugar-loaf, in the midst of an extensive plain, and is thirty stadia in height.—Josephus. The ascent is so easy that one may ascend on horseback. On the top there is a plain two miles in circumference. Flavius Josephus, the historian and governor of Galilee,

caused the summit of this mountain, for two miles and a half, to be surrounded with walls. The inhabitants of Tabor long braved the power of the Roman armies; but, being deprived of water, they were forced to surrender to Placidius the general of Vespasian. Several churches and monasteries were built upon this mountain by St. Helen. Tabor was also the seat of a bishop, dependent on the patriarch of Jerusalem. When Godfrey of Bouillon seized on this mountain, he repaired the ancient churches. Under Baldwin I., in 1113, the Saracens retook Tabor. It again fell into the hands of the Christians; but the Catholic standard was by Saladin pulled down the year after, and all the churches destroyed. The Christians retook it in 1253, and rebuilt them. Pope Alexander IV. granted Tabor to the Templars who fortified it again. At length, in the course of 1290, the sultan of Egypt destroyed and laid waste the buildings of this mountain which could never be repaired afterwards; so that it is now uninhabited.

TABOR, a city given by the Zebulonites to the Merarites. 1 Chron. vi. 77.

TABOR, a circle of Bohemia, bounded on the north by the circle of Czaslau, on the east by Moravia, and on the south and west by the circle of Budweis. Its extent is 1270 square miles; population nearly 160,000. Its soil is fertile, and adapted both to tillage and pasturage. Here are manufactures of woollen, cotton, and linen; and the higher grounds contain productive mines. Bohemian is the only language spoken.

TABOR, a town of Bohemia, the capital of a circle, is situated on a hill, on the river Luschnitz, eighty-eight miles west by north of Brunn, and forty-nine south by east of Prague. It is fortified, and naturally strong; but has been frequently taken. It contains 3800 inhabitants. The Hussites called it Hradistic Hory Tabor, or the camp of Mount Tabor; and as it was their capital they took from it the name of Taborites.

TABORITES, or **THABORITES**, in ecclesiastical history, were a branch or sect of the Hussites, who, towards the beginning of the fifteenth century, dividing into several parties, one of them retired to a little mountain or rock, situate in Bohemia, fifteen leagues from Prague, and there put themselves under the conduct of Ziska. They now built a fort or castle, and a regular city, which they called Tabor or Thabor, either from the general word thabor, which in the Sclavonic language signifies castle; or from the mountain Tabor, mentioned in Scripture; and hence they became denominated Thaborites. The other party were denominated Calixtins.

The Taborites demanded the erection of a new church and hierarchy, in which Christ alone should reign, and all things should be carried on by a divine direction and impulse. In maintaining these demands, some of their leaders went so far as to flatter themselves with the chimerical notion, that Christ would descend in person upon earth, armed with fire and sword, to extirpate heresy, and purify the church. This enthusiastic class of Hussites alone, Mosheim says, we are to look upon as accountable for all those acts of violence which are too indiscriminately laid to the charge of the Hussites in gene-

ral, and to their two leaders, Ziska and Procopius, in particular. After the time of the council of Basil, in 1433, which endeavoured, though without success, to reconcile the Taborites with the Roman pontiff, they began to review their religious tenets, and their ecclesiastical discipline, with a design to render them more perfect. This review, conducted with great prudence and impartiality, gave a rational aspect to the religion of this sect, who withdrew themselves from the war with Sigismund, in which they were engaged, abandoned the doctrines, which, upon serious examination, they found to be inconsistent with the genius and spirit of the gospel, and banished from their communion all those whose disordered brains or licentious manners might expose them to reproach. The Taborites, thus new-modelled, were the same with those Bohemian brethren (or Picards, i. e. Beghards, as their adversaries call them) who joined Luther and his successors at the Reformation, and of whom there are at this day many of the descendants and followers in Poland and other countries.—Mosh. Eccl. Hist. vol. iii.

TABOUROT (Stephen), a French poet, born at Dijon in 1549. He was king's advocate in the parliament of Dijon; and was a man of genius, hut addicted to trifles; and his poetry was licentious agreeably to the taste of the times. He published *Les Bigarrures*, Paris, 1582; and *Les Touches*, Paris, 1585; with some other pieces; in all of which he assumed the whimsical title of Lord of Accords. He died July 24th, 1561, aged forty-six.

TABRACA, an ancient sea-port town of Africa, near Hippo. It was made a Roman colony. The forests abounded with monkeys. Plin. v. 3.

TACAMAHAC, or **TACAMAHACA**, in pharmacy, a solid resin, improperly called a gum in the shops. It exudes from a species of poplar, and is in repute for mitigating pains and aches, and is also reckoned a vulnerary. See **MATERIA MEDICA**.

TACARIGUA, a large lake of South America, in the province of Venezuela, not to be confounded with the lake of Valencia, to which the Indians give the same name. This lake is in fact a bay, except that a bar of quicksand frequently cuts off its communication with the sea. Its form is circular. It measures about seven leagues from the sea on the north-east, to its deepest recess on the south-east, and abounds in all kinds of sea fish. It is particularly remarkable for the great number of alligators which are seen in it.

TACCA, in botany, a genus of plants belonging to the class of dodecandria and order of trigynia. The flower is above. The corolla has six petals, and is vaulted. The calyx is hexaphyllous; the fruit a dry, angular, three-celled berry. There is only one species; viz. *T. pinnatifida*.

TACFARINAS, a Numidian, who, after serving some time in the Roman legions, became a general in his own country, and commanded an army against its conquerors in the reign of Tiberius. Tac. Ann. ii.

TACHA. See **TACHAU**.

TACHAMPISO, an island in the Nile, near

Thebais. The Egyptians held one-half of it, and the Ethiopians the other. Herodot. ii.

TACHE', *n. s.* From tack. Any thing taken hold of; a catch; a loop; a button.

Make fifty *taches* of gold, and couple the curtains together with the *taches*. *Ezod. xxvi. 6.*

TAC'IT, *adj.* } Fr. *tacite*; Lat. *tacitus*. Silent; implied;
TAC'ITLY, *adv.* }
TACITURN'ITY, *n. s.* } not expressed by words: the adverb corresponding: taciturnity, habitual silence.

The strictest of natures
Have not more gift in *taciturnity*. *Shakspeare.*

As there are formal and written leagues respective to certain enemies, so is there a natural and *tacit* confederation amongst all men against the common enemy of human society, pirates. *Bacon's Holy War.*

Some women have some *taciturnity*,
Some nunneries some grains of chastity.

In elective governments there is a *tacit* covenant, that the king of their own making shall make his makers princes. *L'Estrange.*

Captiousness not only produces 'misbecoming expressions and carriage, but is a *tacit* reproach of some incivility. *Locke.*

While they are exposing another's weaknesses, they are *tacitly* aiming at their own commendations. *Addison.*

Indulgence to the vices of men can never be *tacitly* implied, since they are plainly forbidden in scripture. *Rogers's Sermons.*

Too great loquacity, and too great *taciturnity* by fits. *Arbutnot.*

TACITA, in the Roman mythology, the goddess of Silence. King Numa Pompilius paid particular veneration to her.

TACITUS (Caius Cornelius), a celebrated Roman historian, and one of the greatest men of his time, born about A. U. C. 809. He applied himself early to the bar, in which he gained high reputation. Having married the daughter of Agricola, the road to public honors was open to him under Vespasian and Titus; but during the sanguinary tyranny of Domitian, he and his friend Pliny retired from public affairs. The reign of Nerva restored these luminaries of literature to Rome, and Tacitus was engaged, in 850, to pronounce the funeral oration of the venerable Virginius Rufus, the colleague of the emperor in the consulship, and afterwards succeeded him as consul A. D. 97. It is supposed that he died in the end of the reign of Trajan. His works which remain are, 1. Five books of his History. 2. His Annals. 3. A Treatise on the Different Nations who then Inhabited Germany. 4. The Life of Agricola. 5. A Treatise on Eloquence. No ancient author has obtained a more splendid reputation than Tacitus. Kings, princes, and authors of all ranks have read and admired him, though a spirit of liberty runs through his whole works. Never were description and sentiment so beautifully blended, nor the actions and characters of men delineated with such precision; in short he has all the merits of other authors without their defects. There have been five translations of his works into English.

TACITUS (M. Claudius), an excellent emperor of Rome, who succeeded Aurelian A. D. 275. See **ROME**.

TACK, *v. a.* Brcton *tacher*. See **ATTACH**. To fasten to any thing; join; unite: to hold tack is to last; hold out.

Martilmas beefe doth bear good *tack*,
When country folke do dainties lacke. *Tusser.*

There's but a shirt and a half in all my company;
and the half shirt is two napkins *tacked* together, and
thrown over the shoulders like a herald's coat without
sleeves. *Shakspeare.*

Of what supreme almighty power
Is thy great arm, which spans the east and west,
And *tacks* the centre to the sphere! *Herbert.*

If this twig be made of wood
That will hold *tack*, I'll make the fur
Fly 'bout the ears of that old cur. *Hudibras.*

True freedom you have well defined:
But living as you list, and to your mind,
And loosely *tacked*, all must be left behind. *Dryden.*

I *tacked* two plays together for the pleasure of va-
riety. *Id.*

At each *tack* our little fleet grows less,
And, like maimed fowl, swim lagging on the main. *Id.*

Frame so as to be covered with the hair-cloth, or a
blanket *tacked* about the edges. *Mortimer.*

The symmetry of clothes fancy appropriates to the
wearer, *tacking* them to the body as if they belonged
to it. *Grew.*

They serve every turn that shall be demanded, in
hopes of getting some commendam *tacked* to their sees,
to the great discouragement of the inferior clergy. *Swift.*

TACK, *v. n.* Probably from *tackle*. To turn a
ship.

This verseriam they construe to be the compass,
which is better interpreted the rope that turns the
ship; as we say, makes it *tack* about.

Broune's Vulgar Errors.

Seeing Holland fall into closer measures with us
and Sweden, upon the triple alliance, they have
tacked some points nearer France. *Temple.*

On either side they nimbly *tack*,
Both strive to intercept and guide the wind. *Dryden.*

They give me signs
To *tack* about, and steer another way. *Addison.*

TACK, in ship-building, a rope used to confine
the foremost lower corners of the courses and
stay-sails in a fixed position when the wind
crosses the ship's course obliquely; also the rope
employed to pull out the lower corner of a stud-
ding-sail or driver to the extremity of its boom.
The mainsail and foresail of a ship are furnished
with a *tack* on each side, which is formed of a
thick rope tapering to the end, and having a
knot wrought upon the largest end by which it
is firmly retained in the clue of the sail. One
tack is thus always fastened to the windward, at
the same time that the sheet extends the sail to
the leeward.

TACK is also applied by analogy to that part
of any sail to which the *tack* is usually fastened.
A ship is said to be on the starboard or larboard
tack when she is close hauled, with the wind upon
the starboard or larboard side; and in this sense
the distance which she sails in that position is
considered as the length of the *tack*; although
this is more frequently called **BOARD**. See that
article.

To **TACK** is to change the course from one
board to another, or turn the ship about from

the starboard to the larboard *tack*, in a contrary
wind. Thus a ship being close hauled on the
larboard *tack*, and turning her prow suddenly to
windward, receives the impression of the wind
on her head-sails, by which she falls off upon
the line of the starboard *tack*. **Tacking** is also
used, in a more enlarged sense, to imply that
manœuvre in navigation by which a ship makes
an oblique progression to the windward in a
zigzag direction. This, however, is more usually
called *beating* or *turning* to windward. See **NA-
VAL TACTICS, NAVIGATION, and SAILING.**

TACKLE, *n. s.* } Welsh *tacel*; Belg. *tuc-*
TACKLED, *adj.* } *ckel*, a rope; Isl. *lang*. An
TACKLING, *n. s.* } arrow: all the instruments
of sailing in a ship: *tackled* is, made of ropes;
tacked together: *tackling*, a synonyme of *tackle*.

The *takil* smote, and in it went. *Chaucer.*

After at sea a tall ship did appear,
Made all of heben and white ivory,

The sails of gold, of silk the *tackle* were,
Mild was the wind, calm seemed the sea to be.
Spenser.

My man shall

Bring thee cords, made like a *tackled* stair,
Which to the high top-gallant of my joy
Must be my convoy in the secret night. *Shakspeare.*

Tackling, as sails and cordage, must be foreseen
and laid up in store. *Bacon's Advice to Villiers.*

They wondered at their ships and their *tacklings*.
Abbot.

As for *tackle*, the Bœotians invented the oar; Dæ-
dalus, and his son Icarus, the masts and sails.
Heylin.

A stately ship

With all her bravery on, and *tackle* trim,
Sails filled, and streamers waving,
Courtied by all the winds that hold them play.
Milton.

She to her *tackle* fell,
And on the night let fall a peal
Of blows so fierce, and pressed so home,
That he retired. *Hudibras.*

I will furnish him with a rod, if you will furnish
him with the rest of the *tackling*, and make him a
fisher. *Walton.*

Ere yet the tempest roars,
Stand to your *tacle*, mates, and stretch your oars.
Dryden.

Being at work without catching any thing, he re-
solved to take up his *tackle* and be gone. *L'Estrange.*

Red sheets of lightning o'er the seas are spread;
Our *tackling* yield, and wrecks at last succeed.
Garth.

If he drew the figure of a ship there was not a rope
among the *tackle* that escaped him.

Addison's Spectator.

TACQUET (Andrew), a Jesuit of Antwerp,
who flourished in the seventeenth century. He
was a most laborious writer in mathematics;
and published a Treatise on Astronomy, an edi-
tion of Euclid, and many other tracts. His
works were collected and printed at Antwerp
in one large volume, folio, 1669. He died in
1660.

TACTICS, *n. s.* Gr. *τακτική*. The art of
ranging men in the field of battle.

When Tully had read the *tacticks*, he was thinking
on the bar, which was his field of battle. *Dryden.*

TACTICS, MILITARY and NAVAL, in their ge-
neral acceptation, relate to those evolutions,
manœuvres, and positions, which constitute the

main spring of military and naval finesse: they are the means whereby discipline is made to support the operations of a campaign, and are, in every regular service, studied for the purpose of training all the component parts according to one regular plan or system; whereby celerity, precision, and strength, are combined, and the whole rendered completely efficient.

The Greeks were skilful in this part of the *military* art; having public professors of it, called *tactici*, who taught and instructed their youth. We have an account of the progress of this art among them in Thucydides, Xenophon, and Polybius. Ælian also hath a particular book on this subject; and there is a great deal of it in Arrian, in his History of Alex. M. and in Mauritius, and Leo Imperator. But the Romans may be considered the first nation whose military array could be termed regular, and whose forces maintained that order which rendered each inferior individual subject to the control of certain subaltern officers commanding small bodies, corresponding with our sections; which being again compacted, under officers of a second class, formed small divisions, as in our platoons, or companies; and which divisions, being collected under a third class of officers, constituted what we term battalions. The soldiers of ancient Italy were not only inured to great hardships, as a part of their usual exercise, but were taught many evolutions suited to the modes of warfare in those days. Time has occasioned a considerable change in that particular; for, since the invention of gunpowder, our battles have frequently been decided by distant cannonades: and by no means resemble those arduous conflicts in which the heroes of old used to engage, individually contending for the day, and causing the whole field to resemble an infinity of single combats. In this practice all barbarous nations seem uniformly to agree: the sword, the tomahawk, the club, &c., being the chief instruments; though in some instances the javelin, or spear, or the bow and arrow, may be primarily resorted to. Hence such warfare is far more sanguinary than that carried on with fire arms; which rarely do much execution, unless when aided by artillery, and then only when at such distances as to be within reach of case shot. It will no doubt surprise most of our readers, but it is strictly true, that, taking the average quantity of musket ammunition expended, as a sum to be divided by the number of killed and wounded, not more than one shot in fifty will be found to take effect. Thus, after a battalion of 1000 men may have fired twenty rounds per man, making in all 20,000 discharges of musketry, they will have made terrible havoc if 400 of the enemy be disabled. Hence we find that the great features in decisive actions are few indeed; and they depend chiefly on tactics. Thus where a large force is brought to bear upon any particular point, while the enemy is kept in ignorance as to the object in view; or where certain advantages of locality are gained, merely by dint of superior science in the art of conducting troops by the shortest means, and in the greatest order; or where by certain evolutions a small force is made to supply the purpose of a larger, or to resist,

independently of entrenchments, &c., a more numerous body: all these evince the presence of the man of tactics, and qualify him for the designation of an able general.

We have also another branch, which is in a degree secondary, because it depends greatly on the success of the former; namely, the arrangement, or disposition, of a line, in such manner as may allow each description of force to act with effect; this can be done only when the nature of the service to be performed is suited to the nature of the troops by which it is to be attempted. In this we necessarily mean to restrict the operations of infantry to storming parties, cavalry to champaign operations, and artillery to situations where it can be duly protected, while rendering essential service. Hence the able tactician always arranges his force in such manner as to allow each to perform its duty without interfering with the evolutions of any other class; and, in what is called manœuvring his army, never fails to estimate the distances, and the time in which each may execute the assigned duty; so that the whole may coincide with one great intention, and insure success by the accurate execution of its respective functions; were it to be otherwise, the whole must be subject to disorder; one failure often leading to the most serious consequence; the same as is caused by the want of a cog, or tooth, of any wheel in a piece of machinery. From this it may be seen how great a superiority that commander must possess who, by means of this science, fully comprehends the most ready arrangement of troops, where change of position becomes necessary; and who has, in the first instance, so disposed them as to be able to make those changes (even under the disadvantages ever attendant upon such necessity) with celerity, and in good order.

TACTICS, NAVAL, relate to those operations, in the management of a vessel, which enable her to attain any particular object, such as reaching a port, avoiding danger, gaining an advantage over an enemy, &c. In a more extended sense, they denote those manœuvres, stratagems, and deceptions, employed by the commander of a fleet, for the purpose of gaining a weather-gage, cutting off any part of a line, or attacking any particular portion thereof, in such manner as may either defeat the views of a hostile fleet, or subject it to loss and discomfiture. The old system of tactics in this, as well as in the military branch, was burdened with ceremonies, and with received opinions, which were held to be inviolable: the difference of one or two ships in favor of the enemy, was considered a sufficient excuse for a variety of precautions generally amounting to forbearance from engaging the superior power; and, although we certainly can count a number of gallant exploits performed by our fleets when somewhat inferior to the enemy, it has been reserved for latter times to exhibit what could be done by the British navy, even when opposed to nearly double their own force. This wonderful change was introduced by Rodney; who, in the year 1782, engaged the French fleet under count de Grasse; when, by boldly cutting off a part of its rear, he compelled nearly half the enemy's

force to surrender; the rest sought their safety in flight. Since that date admiral Jervis, by a skilful manœuvre, cut off a large portion of a Spanish fleet, near Cape St. Vincent's (whence the peerage bestowed on him received its designation); but the late lord Nelson appears most conspicuous in that mode of attack which, in general, secured a victory. The battle of the Nile was doubtless a master-piece of tactical science; it merits notice from its simplicity, and, if we may be so bold as to use the term, its infallibility. The manœuvre he used was, to throw two of his ships upon every one of the weathermost of the enemy's line, by causing his fleet to divide as it approached them; consequently including each French ship between two of ours. The residue, which were moored in a line a-head, fully expected to see ours range up their whole length, and oppose ship to ship. They saw their error when it was too late; being to leeward, it was impossible for them to render efficient aid, and they fell in detail; with the exception of a very small portion, which escaped by putting out to sea, whither we were not in a condition to follow with any hopes of overtaking them.

In the battle of Trafalgar, in which the immortal Nelson quitted his earthly frame, the combined fleets were drawn up in the form of a crescent, and awaited our attack, which was made in a double column, apparently bearing down upon their centre. This novel mode of coming into action kept the enemy completely in suspense; it threatened every part of their line. If our two columns had turned the same way, they would have been able to do infinite damage in that quarter, before the other wing of the enemy could come up to succor their overpowered friends: if the two columns should cut through the centre, they must destroy it, and effectually separate the two wings, so as to leave them ignorant of each others fate. Such was the fact: the enemy, though superior in numbers, lost no less than nineteen sail of the line.

Perhaps nothing can place a fleet in a more dangerous state, and render it less able to resist an attack, than making sail before the wind, in a line of battle a-head, to avoid a pursuing enemy. In such a case, whenever the rear of that line can be brought to action, it becomes subject to an accumulating force, in consequence of the pursuing fleet thickening upon it; while the van of its own line, being to leeward, must make many tacks, or at least two long ones, before it can succor its rear. The disadvantage must be very great even if all the ships, on both sides, sail upon an exact equality; but, as that is never the case, many of the flying ships will be probably driven completely to leeward, and never be able to afford the smallest assistance. Yet British seamen, even when compelled to retire before a very superior force, generally manage, by some well-contrived device, to intimidate their pursuers, or to put on so good a face as to convince them of the dear price at which the victory is to be bought. Of this we cannot quote a more appropriate instance than the escape of five sail of our ships, under the command of admiral Cornwallis, from no less than nineteen sail of

French ships of the line: an escape resulting entirely from the manœuvres of the British admiral; whereby he fully convinced the French that a large force was at hand. The present unparalleled state of discipline, throughout our navy, would, of itself, give us the command of the ocean; but we are greatly indebted, at the same time, to an excellent code of signals, both for the day and the night, whereby every operation and manœuvre may be directed with readiness and perspicuity.

When orders are given to clear ship for action, the boatswain and his mates whistle, and call at the various hatchways, to warn all who are between decks; the hammocks, or beds, are instantly unhooked, packed, and sent on deck, to be put into the nettings on the waist, fore-castle, quarters, poop, &c., where they serve as an excellent defence against musketry. While some of the seamen are thus employed between decks, others are aloft securing the yards in chain slings, so as to prevent them from falling when the haul-yards may be severed by cannon shot; materials for repairing the rigging are also placed in readiness; shot plugs, for stopping holes, near or under the surface of the water, are dispensed; and every attention is paid to ascertain that the pumps are in order, so as to clear the hold in case of leaks. The decks are cleared of every incumbrance, by the removal of chests, &c., into the hold; the various gun tackles are inspected; and all the necessary implements, such as powder ladles, worms, rammers, sponges, &c., are duly supplied. All being ready, the surgeon and his mate, together with the chest of medicines, instruments, bandages, &c., are prepared in the cock pit; that is, down the hatchway, below the ordinary reach of the enemy's shot. The officers and men repair to their posts, the powder room is opened, the hatches are all laid, the marines drawn up on the fore-castle, quarter-deck, and poop, the guns are run out and levelled, and the courses (that is, the lower sails) are clued up, to prevent their being set on fire by the discharges from the cannon; also to render the ship more manageable.

The greatest attention is always paid to taking a good aim before a gun is fired; that every shot may hit some part of the enemy's hull; the nearer to the water's edge the better. The captain, master, purser, &c., remain on deck to fight the ship, and to note down all occurrences, while the signal master attends to and answers whatever signals may be thrown out of the commander of the fleet, or division. It is ever a primary object to place the ship in such a position as may annoy the enemy most; yet, at the same moment, evade his principal defences: this is best done by laying diagonally upon her quarter, or bow, and especially across her stern, so as to rake her fore and aft; whereby her guns will soon be dismounted, and the men driven from their quarters. This description of the manner in which the battle is carried on by each ship will serve as an illustration of the whole; but it may be necessary to add that the disposition of a fleet must be suited to the position the adversary may have assumed. When an enemy opposes a direct line, opposite to that of

his own fleet, the admiral rarely does more than make the signal for line of battle abreast, perhaps a cable's length asunder, thus coming at once to close engagement, ship opposed to ship, or rather the two fleets intermixed alternately, their heads laying different ways: if they should pass each other, it is usual to put about, and resume the engagement in the same manner. When the enemy bear down in a line a-head, it is customary to receive them in the same manner, to prevent their cutting off a part of the line; this depends greatly on the direction of the wind; but, if it be on the beam, that is full on the side, or in any direction affording the means of aiding your van, without delay, by a press of sail, such a mode of attack will subject the enemy to have his own line cut, as was done by Rodney; or doubled upon, as in the battle of the Nile.

During an engagement, as the courses are commonly hauled up, the top-gallant sails and stay-sails are also furled. The movement of each ship is chiefly regulated by the main and fore-top sails, and the jib, reserving the mizen to fill, or to be thrown a-back, as an aid, either to accelerate the ship, or as a check to prevent her passing the enemy. The frigates, tenders, and other small vessels generally lay to, or hover about in the rear, to repeat signals, or to aid crippled ships. These, not being considered as ships of the line, are not attacked, except by vessels of their own class; therefore, when a fleet is not well manned, it is common to take all the spare hands from such to assist on board the fighting ships. When a fleet is superior in numbers, it is proper to keep some of them in reserve, stationing them behind the weaker parts of the line to succor such as may, by the loss of masts, &c., become unmanageable, and to take advantage of any opportunity to chase, and lay aboard of whatever of the enemy's ships may quit the line for the purpose of escaping. In order to observe what is going on, the admiral generally removes to some frigate, on board which he hoists his flag; near him should be some of the best sailing cutters, brigs, &c., to convey orders which could not be accurately delivered by signal, or by telegraph.

Boarding is most commonly resorted to by privateers, in their attacks upon merchant vessels; but among ships of the line is rarely practised. Our commanders are perhaps more forward than those of any other nation, except the Turks, in this kind of enterprise, which is replete with hazard. The best mode of boarding, especially if there be any swell, is to keep on the enemy's weather quarter; now and then, if the sailing of your ship will allow yawing, so as to throw your fire into her stern: when, by this means, you have done any execution, it will be proper to pass close under the enemy's stern, raking her fore and aft with your guns double shotted, and then lay her aboard upon her lee beam, having your tops well manned to fire upon the enemy's decks, on which also grenades, stink pots, fire balls, &c., should be discharged. Having grappled the ship to your adversary's chains, your boarders jump into her, under the cover of the fire of your small arms. In case

of repulse, the attack to leeward is most favorable to the retreat of your men; besides, it is far easier to cast off from the enemy, than it would be if you were to windward of her.

The writers on naval tactics have been but few, indeed, considering the importance of the subject; and the only countries that have produced writers on this subject, so far as we know, are France and Britain, particularly the former. One would be led to imagine that Britain, from its insular situation, having bred so great a number of excellent seamen, and having so often been engaged in naval contests, would naturally have produced a number of writers on this, as well as on subjects of much less consequence to it as a nation. The reader will, however, no doubt be surprised to hear, that till lately we had only the treatise on naval tactics, entitled *An Essay on Naval Tactics, &c.*, by John Clerk, esq., of Eldon, near Edinburgh; most of the other treatises published in Britain on this subject being either translations from the French, or remarks upon the French authors. Some of the principal French treatises on naval tactics are the following: 1. *L'Art des Armées Navales, ou Traité des Evolutions Navales*, par Paul L'Hoste, 1 vol. folio, printed at Lyons, 1727. This book was translated and published by Christopher O'Bryen, esq., in 4to., in 1762. 2. *Tactique Navale, ou Traité des Evolutions et des Signaux*, par M. le Viscompte de Morogues, 4to., Paris, 1763. 3. *Le Manœuvrier*, par M. Bourdè de Villehuet. 4. *L'Art de Guerre en Mer, ou Tactique Navale, &c.*, par M. le Viscompte de Grenier. Translations of the two last have appeared in English in 4to., in 1788, under the name of the Chevalier de Sauseuil; and a translation of parts of the three last is in the second volume of the *Elements and Practice of Rigging and Seamanship*, published at London in 1794. Other books on evolutions and tactics are *Théorie de la Manœuvre des Vaisseaux*, Paris, 1639. *Pilot's Theory of working Ships applied to Practice, &c.*, translated by Stone, 1743. *De la Manœuvre des Vaisseaux, ou Traité de Mécanique et de Dynamique, &c.*, par M. Bouguer. *The British Mars, &c.*, by William Flexney, 1763. *A Sea Manual*, by Sir Alexander Schomberg, 1789. *A View of the Naval Force of Great Britain, &c.*, by an Officer of Rank, 1791; and the ingenious treatise on *Naval Tactics* by captain Hamstead.

TACTILE, *adj.* Fr. *tactile*; Lat. *tactilis, tactum*. Susceptible of touch.

At this proud yielding word
She on the scene her *tactile* sweets presented.

Beaumont's Psyche.

We have iron, sounds, light, figuration, *tactile* qualities; some of a more active, some of a more passive nature.

Hale.

TACUNGA, a province of Quito, bounded east by the valley of Vicoso, north by the province of Quito, north-west by that of Esmeraldas and also Guayaquil, south-west by that of Chimbo, and south by that of Ambato. It is twenty-one leagues long from east to west, and fourteen wide from north to south; and of a cold temperature, but abounds in pasturage. It produces also wheat, barley, and rye, and wools of many

kinds. It likewise abounds throughout with nitre. Tacunga, the capital, is situated in an extensive plain to the south of Quito, near the Cordillera of the Andes.

TADCASTER, a market-town of Barkstone-Ash wapentake, west-riding of York, situate on the river Wharfe, over which is a good stone bridge, nine miles S.S.W. of York, and 187 north by west from London. The town is neat, well-built, and pleasant. Besides the church, here is a free grammar-school, a hospital, and some charity-schools. It was anciently a Roman station, called Calcaria. The neighbourhood produces much limestone. Market on Thursday. Fairs, the last Wednesday in April, May, September, and October. It is a vicarage.

TADMOR. See **PALMYRA**.

TAD'POLE, *n. s.* Sax. *tað*, toad, and *pola*, a young one. A young shapeless frog or toad. I'll broach the *tadpole* on my rapier's point.

Shakspeare.

Poor Tom eats the toad and the *tadpole*. *Id.*
A black and round substance began to dilate, and after a while the head, the eyes, the tail, to be discernible, and at last become what the ancients called *gyrinus*, we a porwidge or *tadpole*.

Broune's Vulgar Errors.

The result is not a perfect frog, but a *tadpole*, without any feet, and having a long tail to swim with.

Ray.

TÆNARIA, festivals held in honor of Neptune at Tænarus.

TÆNARUS, a promontory of Laconia, the most southern point of the Morea, where Neptune had a temple. It is now called Matapan. It had a large and deep cavern, whence issued a black unwholesome vapor (probably fixed air, or carbonic acid gas), whence the poets feigned that it was one of the entrances to hell, through which Hercules dragged the triple-headed infernal dog Cerberus up to the earth. Pausanias says that this cavern was the resort of a large serpent whose bite was mortal, and which Hercules killed and carried to Eurystheus; and that this gave rise to the story of his chaining the dog of hell.

TÆNARUS, a town of Laconia, forty stadia from the cape, famous for beautiful green marble.

TÆNARUS, a son of Neptune who gave name to the cape, town, and festivals.

TÆNIA, in architecture, a member of the Doric capital resembling a square fillet, serving instead of a cymatium, being made fast to a capital below the triglyphs, whereof it seems the base.

TÆNIA, in entomology, the tape-worm, a genus of animals belonging to the class of vermes and order intestina. The body is long, depressed, and jointed like a chain, and contains a mouth and viscera in each joint. According to Gmelin there are ninety-two species; all which inhabit the intestines of various animals, particularly of quadrupeds. The *tænia* appears destined to feed on such juices of animals as are already animalised, and is therefore most commonly found in the alimentary canal, and in the upper part, where there is the greatest abundance of chyle; for chyle seems to be the natural food of the *tænia*. As it is thus supported by food which is already digested, it is destitute of the complicated

organs of digestion. Seven species are peculiar to man. See **ENTOMOLOGY**.

TÆNIAS, a part of lake Mæotis. Strabo.

TAENSA, a town and settlement of West Florida, on the east channel of the Mobile, on the side of an ancient Indian town. The wax tree abounds near it. See **MYRICA**.

TAF, or **TAAFFE**, a river of Wales, which rises among the hills in Brecknockshire, from two sources, forming two streams, the Greater and Lesser Taf, which unite their waters below the village of Coed-y Cymmer, on their entrance into Glamorganshire; and thence proceed by Merthyr Tydvil. About twelve miles below this town it receives the Bangoid Taf, a mountain stream which flows into it from the eastward. Lower down it is joined by the Cynon from the west, and a few miles lower by the two Rhondas. It then proceeds nearly southwards by Llandaff, and afterwards by Cardiff, towards the southern sea, which it enters in the small bay of Pinarth. In dry weather the Taf contains little water; but is a handsome stream when swollen by the land floods, and navigable for small craft as far as Cardiff. Over this river the noted bridge of Pont-y-Prydd is built.

TAFFËTA, *n. s.* Fr. and Span. *taffetas*. A thin silk; flimsy talk.

All hail, the richest beauties on the earth!

—Beauties no richer than rich *taffata*. *Shakspeare.*

Never will I trust to speeches penned;

Taffata phrases, silken terms precise,

Three piled hyperboles. *Id. Love's Labour Lost.*

Some think that a considerable diversity of colours argues an equal diversity of nature; but I am not of their mind, for not to mention the changeable *taffety*, whose colours the philosophers call not real, but apparent.

Boyle on Colours.

TAFFETA, or **TAFFETY**, in commerce, a fine smooth silken stuff, remarkably glossy. There are taffeties of all colors, some plain and others striped with gold, silver, &c., others chequered, others flowered, &c., according to the fancy of the workmen.

TAFFI (Andrew), an eminent Italian artist, born at Florence in 1213. Having learned the art of designing in Mosaic from some Greek artists employed in decorating the church of St. Mark in Venice, the chief of whom was Apollonius, he introduced it into Italy. His chief work is a Mosaic piece of our Saviour dead in a chapel at Florence. He died in 1294.

TAFILELT, a large district to the south-east of the Atlas chain, and tributary to the empire of Morocco. It consists of a vast single plain, presenting an unvaried surface, traversed by two rivers running in opposite directions, one of which loses itself in the desert of Augad, the other in the sands of the Sahara. Brackish water is every where found at the depth of twelve feet. The inhabitants live in a patriarchal manner, and are said to be remarkably honest. Dates are the chief produce and wealth. A great number of Shereefs, who boast of themselves as the descendants of Mahomet, live here. Sigilmessa was once the chief place, but the town called Tafielt has now supplanted it. The province is stated by Jackson to contain 650,000 inhabitants.

TAG, *n. s. & v. a.* Isl. *tag*, the point of a lace; Goth. and Swed. *tagg*. A point put to the end of a string; any thing paltry and mean: to fit any thing with a tag; to join (probably for tack).

If *tag* and *rag* be admitted, learned and unlearned, it is the fault of some, not of the law. *Whitgift*.

Will you hence

Before the *tag* return, whose rage doth rend
Like interrupted waters? *Shakspeare. Coriolanus.*
The *tag*-*rag* people did not clap him and hiss him.

They feed on *tag* worms and lugges. *Carew.*
There are other worms; as the marsh and *tagtail*.
Walton.

His courteous host

Tags every sentence with some fawning word,
Such as my king, my prince, at least my lord.

Dryden.

'Tis *tagged* with rhyme, like Berecynthian *Atys*,
The mid-part chimes with art, which never flat is.

Id.

He invited *tag*, *rag*, and bob-tail, to the wedding.
L'Estrange.

Compelled by you to *tag* in rhimes

The common slanders of the times. *Swift.*

Resistance, and the succession of the house of
Hanover, the whig writers perpetually *tag* together.
Id. Miscellanies.

TAGANROG, a town of the south-east of European Russia, in the government of Ekaterinoslav, near the north-west extremity of the sea of Azoph, fortified by Peter the Great. It stands on the cliff of a lofty promontory, containing 6000 inhabitants; and, being the staple of all the mercantile intercourse between the interior of Russia and foreign countries, through the medium of the Don, its traffic is extensive.

TAGARA, a city of ancient India, the metropolis of a large district called Ariaca, which comprehended the greatest part of the Subah of Aurenghabad and the south part of Concan. Arrian says that it was situated about ten days' journey to the east of Pultanah; which, according to the rate of travelling in that country with loaded carts, might be about 100 British miles. This fixes its situation at Deoghir, a place of great antiquity, and famous through all India on account of the pagodas of Elousa. It is now called Dowlat-abad.

TAGES, in the mythology, a son of Genius and grandson of Jupiter, who first taught the Etrurians augury. He was found by a Tuscan ploughman in the form of a clod, and immediately assumed a human shape to teach them augury.—Cicero. Had this divine clod taught them agriculture, instead of augury it would have been a better allegory.

TAGETES, marigold, in botany, a genus of plants belonging to the class of syngenesia and order of polygamia superflua; and in the natural system ranging under the forty-ninth order, compositæ. The receptacle is naked; the pappus consists of five erect awns or beards; the calyx is monophyllous, quinque-dentate, and tubular; and there are four persistent florets of the ray. There are three species; viz. 1. *T. erecta*, the African marigold, is a native of Mexico, but has been cultivated in British gardens since 1596. It has a stem subdivided and spreading. There are many varieties:—1. Pale yellow, or brimstone color, with single, double, and fistulous flowers.

2. Deep yellow, with single, double, and fistulous flowers. 3. Orange-colored, with single, double, and fistulous flowers. 4. Middling African, with orange-colored flowers. 5. Sweet-scented African. These are all very subject to vary; so that unless the seeds are very carefully saved from the finest flowers they are apt to degenerate: nor should the same seeds be too long sown in the same garden. Those who wish to have these flowers in perfection should exchange their seeds with some person of integrity at a distance, where the soil is of a different nature, at least every other year. If this is done the varieties may be continued in perfection. They flower from the beginning of July till the frost sets in.

2. *T. minuta*, the small marigold.

3. *T. patula*, the French marigold, has a simple erect stem, and the peduncles are scaly and multiflorous. It has been cultivated in the British gardens since 1596. There are several varieties; some have larger flowers than others, and their color varies greatly; some are beautifully variegated and others quite plain; but all these are accidents arising from culture, for seeds saved from the most beautiful flowers will degenerate, if they are sown in the same garden for several years together without changing the seeds. These plants have a strong disagreeable scent, especially when handled; for which reason they are not planted near habitations; the flowers of the sweet-scented sort being preferred, especially for small gardens.

TAGUS, ТАГО, or ТЕЈО, a large river of Spain, issues from a spring in the mountains of Albaracin, between Arragon and Old Castile, at the distance of little more than 100 miles from the Mediterranean. Pursuing a westward course to the Atlantic, it passes the palace of Aranjuez, the cities of Toledo, Talavera, Alcantara, Abrantes, and Lisbon, and flows into the sea seven miles below the capital of Portugal. Long before reaching Lisbon it receives the tide, and its volume of water is large throughout; but in so mountainous a country as Spain river navigation is very limited: that of this river is not at present carried farther than Abrantes in Portugal. Several places on or near its banks, such as Santarem, Almaraz, and Talavera, were the scenes of military operations in the last war.

TAHPANHES, or ТЕНAPHNEHES, or Hanes, an ancient city of Egypt, supposed to be the same with Daphnæ, about sixteen miles south of Pelusium, on the east bank of the Nile. To this city the remnant of the Jews left by Nebuchadnezzar retired, after the murder of Gedaliah. It was afterwards taken by Nebuchadnezzar.—Jer. xliiii. 1—11. Ezek. xxx. 18.

TAIL, *n. s. & v. n.* } Sax. *tæg*; Goth. *tagl*.

TAIL'ED, *adj.* } That which terminates certain animals behind; the continuation of the vertebrae of the back hanging behind; the lower, hinder, or pendant part of a thing: 'to turn tail' is to fly: to tail, to pull by the tail, a foolish word of Butler's: tailed is furnished with a tail.

The Lord shall make thee the head, and not the tail; and thou shalt be above, and not beneath.

Deut. xxviii. 13.

Would she turn tail to the heron, and fly quite

out another way ; but all was to return in a higher pitch.

Ofc have I scen a liot o'er-weening cur
Run back and bite, because he was withheld,
Who having suffered with the bear's fell paw,
Hath clapt his *tail* betwixt his legs, and cried.

Shakspeare.

Duretus writes a great praise of the distilled water of those *tails* that hang upon willow trees.

Harvey on Consumptions.

With the helm they turn and steer the *tail*.

Hudibras.

The conquering foe they soon assailed,
First Trulla stavcd, and Cerdon *tailed*. *Id.*
This sees the cub, and does himself oppose,
And men and boats his active *tail* confounds.

Waller.

The lion will not kick, but will strike such a stroke with his *tail* that will break the back of his encounterer.

More.

Rouzed by the lash of his own stubborn *tail*,
Our lion now will foreign foes assail. *Dryden.*
Snouted and *tailed* like a boar, footed like a goat.

Crew.

The *tail fin* is half a foot high, but underneath level with the *tail*. *Id.*

TAIL, in anatomy, is the train of a beast, bird, or fish ; which in land animals serves to drive away flies, &c., and in birds and fishes to direct their course, and assist them in ascending or descending in the air or water.

TAIL, or FEE-TAIL, in law, is a conditional estate or fee, opposed to fee simple. See **FEE**. A conditional fee, at the common law, was a fee restrained to some particular heirs exclusive of others ; as to the heirs of a man's body, by which only his lineal descendants were admitted, in exclusion of collateral heirs ; or to the heirs male of his body, in exclusion both of collaterals and lineal females also. It was called a conditional fee, by reason of the condition expressed or implied in the donation of it, that, if the donee died without such particular heirs, the land should revert to the donor. For this was a condition annexed by law to all grants whatsoever, that, on failure of the heir specified in the grant, the grant should be at an end, and the land return to its ancient proprietor. They therefore called it a fee simple on condition that he had issue. So that, as soon as the grantee had any issue born, his estate was supposed to become absolute by the performance of the condition ; for these three purposes :—1. To enable the tenant to alienate the land, and thereby to bar the donor of his interest in the reversion. 2. To subject him to forfeit it for treason. 3. To empower him to charge the land with rents, commons, and other encumbrances, so as to bind his issue. But, if the tenant did not alienate the land, the course of descent was not altered ; for if the issue had afterwards died, and then the tenant or original grantee had died, without making any alienation, the land, by the terms of the donation, could descend to none but the heirs of his body, and therefore must have reverted to the donor. To subject the lands therefore to the ordinary course of descent, the donees of these conditional fee simples took care to alienate as soon as they had issue ; and afterwards repurchased the lands, which gave them a fee simple absolute, that would descend to the heirs general, according to the com-

mon law. And thus stood the old law with regard to conditional fees : which things, says Sir Edward Coke, are necessary to be known for the sake of annuities, and such like inheritances as are not within the statutes of entail, and therefore remain as the common law. On the other hand the nobility, who wished to perpetuate their possessions in their own families, procured the statute of Westminster the second, de donis conditionalibus, to be made ; which paid a greater regard to the intentions of a donor than to the propriety of such intentions. This restraint revived the ancient feudal restraints originally laid on alienations, by enacting that from thenceforth the will of the donor be observed ; and that the tenements so given (to a man and his heirs) should at all events go to the issue, or, if none, should revert to the donor. Upon this act the judges determined that the donee had no longer a conditional fee-simple, but they divided the estate into two parts, leaving in the donee a new kind of particular estate, which they denominated a fee tail ; and vesting in the donor the ultimate fee simple of the land, expectant on the failure of issue ; which expectant estate is what we now call a reversion. And hence Littleton says that tenant in fee tail is by virtue of this statute. About 200 years intervened between the making of the statute de donis and the application of common recoveries to this intent, in the twelfth of Edward IV. ; which were then openly declared by the judges to be a sufficient bar of an estate tail. For though the courts had, so long before as the reign of Edward III., very often hinted that a bar might be effected upon these principles, yet it was never carried into execution ; till Edward IV., observing (in the disputes between the houses of York and Lancaster) how little effect attainders for treason had on families whose estates were protected by the sanctuary of entails, gave his countenance to this proceeding, and suffered Taltarum's case to be brought before the court ; wherein, in consequence of the principle then laid down, it was in effect determined that a common recovery suffered by tenant in tail should be an effectual destruction thereof. These common recoveries are fictitious proceedings, introduced by a kind of *pia fraud*, to elude the statute de donis, which was found so intolerably mischievous, and which yet one branch of the legislature would not then consent to repeal ; and that these recoveries are now become by long use a most common assurance of lands ; and are looked upon as the legal mode of conveyance by which a tenant in tail may dispose of his lands and tenements ; so that no court will suffer them to be shaken or reflected on, and even acts of parliament have by a 'side-wind' countenanced and established them. This expedient having greatly abridged estates tail, with regard to their duration, others were soon invented to strip them of other privileges. The next that was attacked was their freedom from forfeitures for treason. For, notwithstanding the large advances made by recoveries, in the compass of about sixty years, towards unfettering these inheritances, and thereby subjecting the lands to forfeiture, the rapacious prince then reigning, finding them fre-

quently resettled in a similar manner to suit the convenience of families, had address enough to procure a statute, whereby all estates of inheritance (under which estates tail were covertly included) are declared to be forfeited to the king upon any conviction of high treason. The next attack which they suffered was by stat. 32 Hen. VIII. c. 28, whereby certain leases made by tenants in tail, which do not tend to the prejudice of the issue, were allowed to be good in law, and to bind the issue in tail. But they received a more violent blow in the same session of parliament by the construction put upon the statute of fines, by stat. 32 Hen. VIII. c. 36, which declares a fine duly levied by tenant in tail to be a complete bar to him and his heirs, and all persons claiming under such entail. This was agreeable to the intention of Henry VII., whose policy it was to lay the road as open as possible to the alienation of landed property, to weaken the overgrown power of his nobles. But, as they were not easily brought to consent to such a provision, it was couched, in his act, under obscure expressions. And the judges, though willing to construe that statute as favorably as possible for the defeating of entailed estates, yet hesitated at giving fines so extensive a power by mere implication, when the statute de donis had expressly declared that they should not be a bar to estates tail. But the statute of Henry VIII., when the doctrine of alienation was better received, and the king's will more implicitly obeyed, established that intention. Yet, to preserve the property of the crown from infringement, all estates tail created by the crown are excepted. And the same was done with regard to common recoveries, by stat. 34 & 35 Hen. VIII. c. 20, which enacts that no feigned recovery had against tenants in tail, where the estate was created by the crown, and the reversion continues in the crown, shall be of any force and effect; which is allowing indirectly their full force and effect with respect to ordinary estates tail, where the royal prerogative is not concerned. Lastly, by stat. 36 Hen. VIII., all estates tail are rendered liable to be charged for payment of debts due to the king by record or special contract; as since, by the bankrupt laws, they are also subjected to be sold for the debts contracted by a bankrupt. And, by the construction put on the stat. 43 Eliz. c. 4, an appointment by tenant in tail of the lands entailed to a charitable use is good without fine or recovery. Estates tail, being thus by degrees unfettered, are now reduced again to almost the same state, even before issue born, as conditional fees were in at common law, after the condition was performed by birth of issue. For, 1. The tenant in tail is now enabled to alienate his lands and tenements by fine, by recovery, or by certain other means; and thereby to defeat the interest as well of his own issue, though unborn, as also of the reversioner, except in the case of the crown: 2. He is now liable to forfeit them for high treason: and, lastly, He may charge them with reasonable leases, and also with such of his debts as are due to the crown on specialties, or have been contracted with his fellow subjects in a course of extensive commerce.

TAILLAGE, *n. s.* Fr. *tailler*. Defined below.

Tailage originally signifies a piece cut out of the whole; and, metaphorically, a share of a man's substance paid by way of tribute. In law, it signifies a toll or tax. *Cowell*.

TAILLE, *n. s.* Fr. *taille*. See below.

Taille, the fee which is opposite to fee-simple, because it is so minced or pared that it is not in his free power to be disposed of who owns it; but is, by the first giver, cut or divided from all other, and tied to the issue of the donee. This limitation, or *taille*, is either general or special. *Taille* general is that whereby lands or tenements are limited to a man, and to the heirs of his body begotten; and the reason of this term is, because how many soever women the tenant, holding by this title, shall take to his wives, one after another, in lawful matrimony, his issue by them all have a possibility to inherit one after the other. *Taille* special is that whereby lands or tenements be limited unto a man and his wife, and the heirs of their two bodies begotten. *Cowell*.

TAILOR, *n. s.* Fr. *tailleur*, from *tailler*, to cut. One whose business is to make clothes.

I'll entertain a score or two of *tailors*,
To study fashions to adorn my body.

Shakespeare. Richard III.

Here's an English *tailor* come for stealing out of a French hose; come, *tailor*, you may roast your goose.

Shakespeare.

The knight came to the *tailor's* to take measure of his gown.

Camden.

The world is come now to that pass that the *tailor* and shoe-maker may cut out what religion they please.

Howel.

In Covent-garden did a *tailor* dwell,
That sure a place deserved in his own hell. *King.*

It was prettily said by Seneca, that friendship should not be unript, but unstitch, though somewhat in the phrase of a *tailor*.

Collier.

TAINT, *v. a., v. n., & n. s.* } Fr. *teindre*; of
TAINTLESS, *adj.* } Lat. *tingo*. To im-
TAINTURE, *n. s.* } bue or impregnate
with any thing; corrupt; spoil; be infected:
used in a bad sense generally: the noun substantive and adjective corresponding.

We come not by the way of accusation
To *taint* that honour every good tongue blesses.

Shakespeare.

Her offence
Must be of such unnatural degree
That monsters it; or your forevouched affection
Fallen into *taint*.

Id. King Lear.

Now I
Unspeak mine own detraction; here abjure
The *taints* and blames I laid upon myself.

Shakespeare.

See here the *tainture* of thy nest,
And look thyself be faultless.

Id.

The minds of all men, whom they can acquaint
With their attractions.

Chapman's Odyssey.

They the truth
With superstitions and traditions *taint*.

Milton.

Those pure immortal elements
Eject him *tainted* now, and purge him off
As a distemper.

Id.

My hellhounds shall lick up the draff and filth,
Which man's polluting sin with *taint* hath shed
On what was pure.

Id.

Nothing *taints* sound lungs sooner than inspiring
the breath of consumptive lungs.

Harvey on Consumptions.

A father that breeds his son at home, can keep him
better from the *taint* of servants than abroad. *Locke.*

There is found in the summer a spider called a *taint*, of a red color, and so little that ten of the largest will hardly outweigh a grain.

Browne's Vulgar Errors.

But is no rank, no station, no degree,
From this contagious *taint* of sorrow free? *Prior.*
Salts in fumes contract the vesicles, and perhaps the
tainted air may affect the lungs by its heat.

Arbutnot on Air.

With wholesome herbage mixt, the direful bane
Of vegetable venom *taints* the plain. *Pope.*

No humours gross, or frowzy streams,
Could from her *taintless* body flow.

Swift's Miscellanies.

A sweet-bread you found it *tainted* or fly-blown.

Swift.

The yellow tinging plague
Internal vision *taints*. *Thomson's Spring.*

The spaniel, struck
Stiff by the *tainted* gale, with open nose
Draws full upon the latent prey. *Thomson.*

TAI-TONG, a city of the first rank in China, in Chan-si, in a mountainous country; abounding with medicinal and other plants. It is well fortified, has a strong garrison, and four cities of the second rank, and seven of the third, in its jurisdiction. Its territories abound with lapis lazuli, and a particular kind of jasper called *yieche*, which is as white and beautiful as agate; marble and porphyry are also common; and a great revenue is produced from the skins which are dressed here. 155 miles west of Peking.

TAKA, a considerable district of Nubia, in the track between Shendy and Suakin. It is about three days journey in length, and one in breadth, and of extreme fertility. Its inhabitants are largely composed of Bedouin Arabs. Its dhourra is of the best quality, and is sold in the market of Jidda twenty per cent. higher than that of Egypt. Its camels and oxen are equally celebrated. The people are hospitable, but accused of treachery to strangers. The chief articles imported are tobacco, natron, spices, especially cloves, incense, beads, and hardware: in return for which they give dhourra.

The chief tribe are the Bisharein, who have their bouza huts, and their public women. Wives make no difficulty in receiving strangers into their tents; 'but,' says Burckhardt, with great simplicity, 'this never happened to me: for whenever I presented myself before a tent, the ladies greeted me with loud screams, and waved their hands for me to depart instantly.' These people eat the blood of animals coagulated over the fire, and the liver and kidneys raw; but the milk of the camel and dhourra are their principal articles of food. Like the Bishareins of Atbara, those of Taka are treacherous, revengeful, and addicted to theft. 'A Hadendoa seldom scruples to kill his companion on the road in order to possess himself of the most trifling article of value, if he entertains a hope of doing it with impunity; but the retaliation of blood exists in full force. Among the Hallenga, who draw their origin from Abyssinia, a horrible custom is said to attend the revenge of blood; when the slayer has been seized by the relatives of the deceased, a family feast is proclaimed, at which the murderer is brought into the midst of them, bound upon an angarey, and, while his throat is

slowly cut with a razor, the blood is caught in a bowl, and handed round amongst the guests, every one of whom is bound to drink of it at the moment the victim breathes his last.'—Burckhardt.

TAKE, *v. a. & v. n.*

TA'KER, *n. s.*

TA'KING.

Saxon *tæcan*; Goth. *taku*; Swed. *taga*, barb. Lat. *tugo* of *tango*.

To receive; lay hold on; seize; snatch; arrest; surprise; captivate; entrap; exact; obtain in any way; adopt; employ; swallow; to perform any action; follow; pursue; convey; receive mentally; admit; assume; endure; bear. Such are the principal senses: Dr. Johnson observes, 'This verb, like *prendre* in French, is used with endless multiplicity of relations. Its uses are so numerous that they cannot easily be exemplified; and its references to the words governed by it so general and lax, that they can hardly be explained by any succedaneous terms. But commonly that is hardest to explain which least wants explanation.' It takes the adjuncts *away, care, course, down, from, head, heed to, in, in hand, notice, oath, off, order with, out, part, place, time, up, upon*, as exemplified below. The verb *unter* means to direct the course; have a tendency to; please; gain reception; have a designed effect; catch; fix; and has the adjuncts *after, in with, on, to, up, up with, with, &c.* A taker is one who takes: a taking, seizure; distress or strong affection of mind.

Enoch walked with God, and he was not, for God *took* him. *Gen. v. 24.*

I will take you to me for a people, and I will be to you a God. *Ezekus vi. 7.*

Thou shalt not *take* the name of the Lord in vain.

Ezekus.

Take no usury of him or increase. *Iev. xxv. 36.*

Hath God assayed to *take* a nation from the midst of another? *Deut. iy. 34.*

No man shall *take* the nether or the upper millstone to pledge. *Id. xxiv. 6.*

Thou art *taken* in thy mischief. *2 Sam. xvi. 8.*

Take us the foxes that spoil the vines. *Cant. ii. 15.*

Peradventure we shall prevail against him, and *take* our revenge on him. *Jer. xx. 10.*

He put forth a hand, and *took* me by a lock of my head. *Ezek. viii. 3.*

They shall not *take* shame. *Mic. ii. 6.*

Wheresoever he *taketh* him he teareth him; and he foameth. *Mark ix. 18.*

If any *take away* from the book of this prophecy, God shall *take away* his part out of the book of life. *Rev. xx. 19.*

Five hundred asses yearly *took* the horse, Producing mules of greater speed and force. *Sandys.*

No purposes whatsoever which are meant for the good of that land will prosper, or *take* good effect. *Spenser.*

Damasco, without any more ado, yielded unto the Turks; which the bassa *took* in so good part, that he would not suffer his soldiers to enter it.

Knolles's History of the Turks.

This great bassa was born in a poor country village, and in his childhood *taken* from his Christian parents by such as *take up* the tribute children. *Id.*

I will frown as they pass by, and let them *take* it as they list. *Shakespeare. Romeo and Juliet.*

La you¹ if you speak ill of the devil, how he *takes* it at heart.

Appoint a meeting with this old fat fellow,
Where we may *take* him, and disgrace him for it.
Shakespeare.

More than history can pattern, though devised
And played to *take* spectators. *Id.*

Strike her young bones,
You *taking* airs with lameness! *Id.*

That hand which had the strength, even at your door,

To cudgel you, and make you *take* the hatch. *Id.*
This I *take* it

Is the main motive of our preparations. *Id.*

You must forsake this room, and go with us;
Your power and your command is *taken off*,
And Cassio rules in Cyprus. *Id.*

The smooth pates now wear nothing but high shoes;
and, if a man is through with them in honest *taking*
up, they stand upon security. *Id.*

I *take* not on me here as a physician :

Nor do I, as an enemy to peace,
Troop in the throngs of military men:
But rather

To purge the' obstructions which begin to stop
Our very veins of life. *Shakespeare. Henry IV.*

How will my mother, for a father's death,
Take on with me, and ne'er be satisfied! *Shakespeare.*

He will hang upon him like a disease :

He is sooner caught than the pestilence,
And the *taker* runs presently mad. *Id.*

What a *taking* was he in, when your husband
asked who was in the basket! *Id.*

The words are more properly *taken* for the air or
æther than the heavens. *Raleigh.*

The queen, hearing of a declination of monarchy,
took it so ill as she would never after hear of the
other's suit. *Bacon.*

A following hath ever been a thing civil, and well
taken in monarchies, so it be without too much popu-
larity. *Id.*

You *take* me right, Eupolis; for there is no possi-
bility of an holy war. *Id. Holy War.*

If any of the family be distressed, order is *taken* for
their relief: if any be subject to vice, or *take* ill
courses, they are reprov'd. *Id. New Atlantis.*

Before I proceed, I would *take* some breath. *Bacon.*

It appeared in his face, that he *took* great content-
ment in this our question. *Id.*

Men die in desire of some things which they *take*
to heart. *Id.*

They that come abroad after these showers are com-
monly *taken* with sickness. *Id.*

They meant to *take a course* to deal with particu-
lars by reconcilements, and cared not for any head. *Id.*

To stop schisms, *take off* the principal authors by
winning and advancing them, rather than engage
them by violence. *Id.*

A great vessel full being drawn into bottles, and
then the liquor put again into the vessel, will not fill
the vessel again so full as it was, but that it may
take in more. *Id.*

Though he would have turned his teeth upon
Spain, yet he was *taken order with* before it came to
that. *Id.*

Men once placed *take in with* the contrary faction
to that by which they enter. *Id. Essays.*

Our gracious master is a precedent to his own sub-
jects, and seasonable mementos may be useful: and,
being discreetly used, cannot but *take well with* him.
Id.

Berry coffee and tobacco, of which the Turks are
great *takers*, condense the spirits, and make them
strong. *Id.*

When news were brought that the French king
besieged Constance, he posted to the sea-coast to *take*
ship. *Camden.*

The knight coming to the taylor's to *take* measure
of his gown, perceiveth the like gown cloth lying
there. *Id.*

Why, now you *take* me; these are rites
That grace love's days, and crown his nights:
These are the motions I would see. *Ben Jonson.*

The dear sale beyond the seas increased the num-
ber of *takers*; and the *takers* jarring and brawling one
with another, and foreclosing the fishes, taking their
kind within harbour, decreased the number of the
taken. *Carew.*

Should a great beauty resolve to *take* me in with the
artillery of her eyes, it would be as vain as for a
thief to set upon a new-robb'd passenger. *Suckling.*

His wind he never *took* whilst the cup was at his
mouth, but observed the rule of drinking with one
breath. *Hakewill.*

If I renounce virtue, though naked, then I do it
yet more when she is thus beautified on purpose to
allure the eye, and *take* the heart. *Decay of Piety.*

God's decrees of salvation and damnation have
been *taken up* by some of the Romish and reformed
churches, affixing them to men's particular entities,
absolutely considered. *Hammond.*

The parliament *took upon* them to call an assembly
of divines, to settle some church controversies, of
which many were unfit to judge. *Sanderson.*

Scalger, comparing the two orators, says, that
nothing can be *taken* from Demosthenes, nor added
to Tully. *Denham!*

Few like the Fabii or the Scipios are,
Takers of cities, conquerors in war. *Id.*

The diminution of the power of the nobility they
took very heavily. *Clarendon.*

They silenced those who opposed them, by traduc-
ing them abroad, or *taking* advantage against them
in the house. *Id.*

Resolutions *taken* upon full debate were seldom
prosecuted with equal resolution. *Id.*

He *took* himself to have deserved as much as any
man, in contributing more, and appearing sooner, in
their first approach towards rebellion. *Id.*

Till there were a perfect reformation, nothing
would prosper that they *took* in hand. *Id.*

The bill for *taking away* the votes of bishops was
called a bill for *taking away* all temporal jurisdiction.
Id.

He alone
To find where Adam sheltered *took* his way. *Milton.*

Take to thee from among the cherubim
Thy choice of flaming warriors. *Id.*

I hope you will not expect from me things demon-
strated with certainty; but will *take* it well that I
should offer at a new thing. *Graunt.*

I am contented to dwell on the Divine Providence,
and *take up* any occasion to lead me to its contempla-
tion. *Hale.*

Her lovers' names in order to run o'er, The girl *took* breath full thirty times and more. *Dryden.*

Distressed myself, like you, confined I live, And therefore can compassion *take* and give. *Id.*

If I have been a little pilfering, I *take* it bitterly of thee to tell me of it. *Id.*

Our phoenix queen was pourtrayed too so bright, Beauty alone could beauty *take* so right. *Id.*

At first they warm, then scorch, and then they *take*, Now with long necks from side to side they feed;

At length grown strong their mother fire forsake, And a new colony of flames succeed. *Id.*

Few are so wicked as to *take* delight In crimes unprofitable. *Id.*

I *took* your weak excuses. *Id.*

Take my esteem:

If from my heart you ask or hope for more, I grieve the place is *taken* up before. *Id.*

I can be as quiet as any body with those that are quarrelsome, and be as troublesome as another when I meet with those that will *take* it. *L'Estrange.*

The cat presently *takes* a tree, and sees the poor fox torn to pieces. *Id.*

The ass *takes* up with that for his satisfaction, which he reckoned upon before for his misfortune. *Id.*

Give them one simple idea, and see that they *take* it right, and perfectly comprehend it. *Locke.*

Upon this assurance he *took* physick. *Id.*

He that should demand of him how begetting a child gives the father absolute power over him, will find him answer nothing; we are to *take* his word for this. *Id.*

A multitude, how great soever, brings not a man any nearer to the end of the inexhaustible stock of number, where still there remains as much to be added as if none were *taken* out. *Id.*

I *take* liberty to say that these propositions are so far from having an universal assent, that to a great part of mankind they are not known. *Id.*

Time is *taken* for so much of minute duration as is measured out by the great bodies of the universe. *Id.*

It is not in the power of the most enlarged understanding to frame one new simple idea in the mind not *taken* in by the ways aforementioned. *Id.*

Were the pleasure of drinking accompanied, the moment a man *takes* off his glass, with that sick stomach which, in some men, follows not many hours after, no body would ever let wine touch his lips. *Id.*

The least things are *taken* up by the thumb and forefinger: when we would *take* up a greater quantity, we would use the thumb and all the fingers. *Ray.*

If you slit the artery, thrust a pipe into it, and cast a straight ligature upon that part containing the

pipe, the artery will not beat below the ligature; yet do but *take* it off, and it will beat immediately. *Id.*

No beast will eat sour grass till the frost hath *taken* it. *Mortimer.*

Upon the sea-coast are parcels of land that would lay well for the *taking* in. *Id.*

Madam, were I as you, I'd *take* her counsel. *Philips.*

So soft his tresses, filled with trickling pearl, You'd doubt his sex, and *take* him for a girl. *Tate.*

I *took* a walk in Lincoln's Inn Garden. *Tatler.*

The Carthaginian *took* his seat, and Pompey entered with great dignity in his own person. *Id.*

Honeycomb, on the verge of threescore, *took* me aside, and asked me whether I would advise him to marry? *Addison's Spectator.*

The husband's affairs made it necessary for him to *take* a voyage to Naples. *Id.*

Doctor Moore, in his Ethicks, reckons this particular inclination, to *take* a prejudice against a man for his looks, among the smaller vices in morality, and names it a prosopolepsia. *Id.*

Lovers flung themselves from the top of the precipice into the sea, where they were sometimes *taken* up alive. *Addison.*

Lacqueys were never so saucy and pragmatical as now, and he should be glad to see them *taken* down. *Id.*

Take off all their models in wood. *Id.*

We *took* up arms, not to revenge ourselves, But free the commonwealth. *Id.*

Arnobius asserts that men of the finest parts and learning, rhetoricians, lawyers, physicians, despising the sentiments they had once been fond of, *took* up their rest in the Christian religion. *Id. on the Christian Religion.*

These heads are sufficient for the explication of this whole matter; *taking* in some additional discourses, which make the work more even. *Burnet.*

Tell an ignoramus in place to his face that he has a wit above all the world, and, as fulsome a dose as you give him, he shall readily *take* it down, and admit the commendation, though he cannot believe the thing. *South.*

Is a man unfortunate in marriage? Still it is because he was deceived; and so *took* that for virtue and affection which was nothing but vice in a disguise. *Id.*

This grated harder upon the hearts of man than the strangeness of all the former articles that *took* up chiefly in speculations. *Id.*

It concerns all, who think it worth while to be in earnest with their immortal souls, not to abuse themselves with a small confidence; a thing so easily *taken* up, and so hardly laid down. *Id. Sermons.*

I *take* thee at thy word. *Rowe's Ambitious Stepmother.*

Heightened revenge he should have *took*;

He should have burnt his tutor's book. *Prior.*

Wise men are overborn when *taken* at a disadvantage. *Collier of Confidence.*

Though he that is full of them thinks it rather an ease than oppression to speak them out, yet his auditors are perhaps as much *taken* up with themselves. *Government of the Tongue.*

The living fabrick now in pieces *take*,

Of every part due observation make;

All which such art discovers. *Blackmore.*

We always *take* the account of a future state into our schemes about the concerns of this world. *Atterbury.*

Young gentlemen ought not only to *take* along with them a clear idea of the antiquities on medals and figures, but likewise to exercise their arithmetick in reducing the sums of money to those of their own country. *Asbathnot on Coins.*

Tiberius, noted for his niggardly temper, only gave his attendants their diet; but once he was *taken* with a fit of generosity, and divided them into three classes.

Arbutnot.

Cleombrotus was so *taken* with this prospect that he had no patience.

Wake.

Charity, *taken* in its largest extent, is nothing else but the sincere love of God and our neighbour. *Id.*

Your present distemper is not so troublesome as to *take* you off from all satisfaction. *Id.*

Men in their loose unguarded hours they *take*,
Not that themselves are wise, but others weak.

Pope.

Some Tories will *take* you for a Whig, some Whigs will *take* you for a Tory. *Id.*

Not foes nor fortune *take* this power away,

And is my Abelard less kind than they? *Id.*

Take part in rejoicing for the victory over the Turks. *Id.*

I am possessed of power and credit, can gratify my favourites, and *take* vengeance on my enemies. *Swift.*

As I *take* it, the two principal branches of preaching are, to tell the people what is their duty, and then to convince them that it is so. *Id.*

Though so much of heaven appears in my make,
The foulest impressions I easily *take*. *Id.*

With a two foot rule in his hand measuring my walls, he *took* the dimensions of the room. *Id.*

Miss Betsy won't *take* to her book. *Id.*

This man always *takes* time, and ponders things maturely, before he passes his judgment. *Watts.*

A student should never satisfy himself with bare attendance on lectures, unless he clearly *takes* up the sense. *Id.*

TALAVERA DE LA REYNA, an ancient town of Spain, in New Castile, on the right bank of the Tagus, over which there is a bridge of thirty-five arches, 1200 feet in length. It is surrounded by a fertile plain of vast extent, intersected by the river. Part of the old ramparts are in preservation, but they are little more than an object of curiosity; it is, in a military sense, altogether open. Here are several well built churches, in particular that of the Hieronymites; and two public walks, one on the north, the other on the south of the town. But the dwelling houses are seldom more than one story in height; and the streets are badly paved and crossed by a number of narrow lanes. Its population, including the suburbs, is about 8000. Silk manufactures, established here about the year 1748, are still carried on; and in the neighbouring village of Cervera are manufactures of soap, hats, and earthenware, on a small scale. Talavera contains many Roman monuments; but it does not, as some imagine, correspond to the ancient Eboræ. It fell into the hands of the Moors in 714, continued long in their possession, and, when the Christians succeeded in re-occupying the inland provinces, was repeatedly taken and retaken. In the beginning of the twelfth century it was sacked by the Moors. This place has given birth to several men of eminence, of whom the best known is Mariana the historian. It is memorable for the battle fought on 27th and 28th July 1809, between a French army, amounting to 47,000 men, and an allied force, in which there were 19,000 British, and between 30,000 and 40,000 Spaniards; and in which the French, after making several desperate attacks, were repulsed. Sixty-three miles W. S. W. of Madrid.

TALBOT (William). D D., an eminent English prelate, born in 1659, and educated at

Oxford. In the reign of James II. he preached with great courage and zeal against popery; for which, after the revolution, he was promoted to be dean of Worcester, and afterwards bishop of Salisbury. In 1722 he was made bishop of Durham; published several sermons; and died in 1730.

TALBOT (Catherine), an ingenious lady, was the only child of Edward, second son of bishop Talbot, and born five months after the decease of her father, who died early. Her mother, therefore, accepted the invitation of Dr. Secker, afterwards archbishop of Canterbury, the friend of her late husband, to become a part of their family. Here Miss Talbot received an excellent education, which she much improved by her own application. On the death of the archbishop in 1768, who bequeathed £400 to Mrs. and Miss Talbot, they removed to a habitation of their own; and after a while, in consequence of the declining health of Miss Talbot, to the house of the marchioness De Gray at Richmond, where the latter died of a cancer in her forty-ninth year. This lady was the intimate friend of Mrs. Carter, with whom she kept up a literary correspondence of considerable interest. Her works are Reflections on the Seven Days of the Week, Essays on Various Subjects, Letters to a Friend on the Future State, Dialogues, Prose Pastorals, Imitations of Ossian, Allegories, and poetry.

TALC, or TALK, in the old system of mineralogy, a species of fossil formerly arranged under the magnesian earths; and, in Magellan's edition of Cronstedt's Mineralogy, ranked as a species of Mica. See MICA. There are two varieties, viz.: 1. T. Muscovy, called also lapis specularis, is very common in Russia, and Cyprus; and in the Alps, the Appennines, and many mountains of Germany. It is imported in large quantities into England, and is used by the lantern-makers instead of horn in their nicer works; by the painters to cover miniature pictures; and by the microscope-makers to preserve small objects for viewing by glasses. The ancients used it instead of glass in their windows. It differs from plaster stone in this, that it does not, after being calcined and wetted with water, swell and concrete into a hard stony substance. Muscovy talc and lapis specularis were long considered as the same, but a distinction is now discovered between them. See MINERALOGY. Talc is employed, in places where it is found in considerable quantity, in compositions for earthen vessels, tests and cupels, &c. From its smoothness, unctuousity, and brightness, it has been celebrated as a cosmetic; and former chemists submitted it to a variety of operations, for procuring from it oils, salts, tinctures, magisteries, &c. But all their labors proved in vain.

2. T. Venetian, is not so named from being a production of the territories of Venice (for it is seldom met with in that country), but as an article of Venetian commerce. It abounds in England, Norway, Hungary, Bohemia, Spain, and in many countries of Asia. With half its weight of alkaline salt, it may, in a strong fire, be brought into perfect fusion, though not to perfect transparency; with equal weight, or less of borax, it runs into a beautiful, pellucid, greenish yellow

glass. Talc does not melt with any other earth, nor even bake or cohere with any but the argillaceous; mixtures of it with them all are nevertheless brought into fusion by a remarkably less quantity of saline matter than the ingredients separately would require. Thus equal parts of talc and chalk, with only one-fourth their weight of borax, melt in a moderate heat into a fine transparent greenish glass, of considerable hardness and great lustre. On substituting gypseous earths to chalk, the fusion is as easy, and the glass as beautiful; in color not green, but yellow like the topaz. Talc, with half its weight of sand, and a quantity of nitre equal to both, yields also a transparent topaz yellow glass. See other experiments by Mr. Pott, in Mem. de l' Acad. de Berlin, 1746.

TALC, in the new system of mineralogy, is reckoned by Dr. Thomson a species quite distinct from mica; and is subdivided into three varieties; viz. 1. The scaly talc; 2. The Venetian or common talc; and 3. The shistose talc. See MINERALOGY.

TALCITE, *n. s.* A name given by Kirwan to scaly talc. See MINERALOGY.

TALÉ, *n. s.* } Sax. *tale*, from *tellen*, to
TALÉBEARER, } tell. A narrative; a story;
TALÉBEARING. } information; something told:
hence a number reckoned; numerical account: commonly a slight or petty account of some trifling or fabulous incident: as, 'a tale of a tub': a talebearer is an informer; tattler: always used in an ill or reproachful sense: the other noun substantive corresponding.

We spend our years as a *tale* that is told.

Psalm xc. 9.

Number may serve your purpose with the ignorant, who measure by *tale*, and not by weight. *Hooker.*

My conscience hath a thousand several tongues,
And every tongue brings in a several *tale*,
And every *tale* condemns me for a villain. *Shakspeare.*

Hermia, for aught I could read,
Could ever hear by *tale* or history,
The course of true love never did run smooth. *Id.*

Birds live in the air freest, and are aptest by their voice to tell *tales* what they find, and by their flight to express the same. *Bacon.*

Twelve returned upon the principal pannel, or the *tales*, are sworn to try according to their evidence. *Hale.*

Money being the common scale
Of things by measure, weight, and *tale*;
In all the' affairs of church and state,
'Tis both the balance and the weight. *Hudibras.*
For every bloom his trees in spring afford,
An autumn apple was by *tale* restored.

Dryden's Virgil.

The herald for the last proclaims
A silence, while they answered to their names,
To shun the fraud of musters false:
The *tale* was just. *Id. Knight's Tale.*

The liberty of a common table is a tacit invitation to all intruders; as buffoons, spies, *tale-bearers*, flatterers. *L'Estrange.*

In great families, some one false, pautry *tale-bearer*, by carrying stories from one to another, shall inflame the minds, and discompose the quiet, of the whole family. *South.*

Reasons of things are rather to be taken by weight than *tale*. *Collier on Cloaths.*

The said Timothy was extremely officious about their mistress's person, endeavouring, by flattery and

talebearing, to set her against the rest of the servants.

Arbutnot.

This story prepared their minds for the reception of any *tales* relating to other countries. *Watts.*

TAL'ENT, *n. s.* Lat. *talentum*. So much weight: hence a sum of money; the value differing according to different ages and countries: faculty; power; ability; quality; disposition.

Five *talents* in his debt,

His means most short, his creditors most straight.

Shakspeare.

Many who knew the treasurer's *talent* in removing prejudices, and reconciling himself to wavering affections, believed the loss of the duke was unseasonable

Carendon.

Though the nation generally was without any ill *talent* to the church in doctrine or discipline, yet they were not without a jealousy that popery was not enough discountenanced. *Id.*

He, Agelius, though otherwise a very worthy man, yet, having no *talent* for disputation, recommended Sisinnius, his lector, to engage in a conference.

Waterland.

Two tripods cast in antick mould,
With two great *talents* of the finest gold. *Dryden.*

He is chiefly to be considered in his three different *talents*, as a critic, satirist, and writer of odes. *Id.*

It is the *talent* of human nature to run from one extreme to another. *Swift.*

'Tis not my *talent* to conceal my thoughts,
Or carry smiles and sunshine in my face,
When discontent sits heavy at my heart.

Addison's Cato.

They are out of their element, and logick is none of their *talent*. *Baker on Learning.*

Persons who possess the true *talent* of raillery are like comets; they are seldom seen, and all at once admired and feared. *Female Quixote.*

TALÉNT, ATTIC. The common Attic *talent* of weight contained sixty Attic *minæ*, or 6000 Attic drachmæ; and weighed, according to Dr. Arbuthnot, 56 lbs. 11 oz. 17½ gr. English troy weight. There was another Attic *talent*, by some said to consist of eighty, by others of 100 *minæ*.

TALÉNT, EGYPTIAN AND ANTIOCHIAN. The Egyptian *talent* was 80 *minæ*; the Antiochian also 80; the Ptolematic of Cleopatra 86½; that of Alexandria 96; and the Insular *talent* 120.

TALÉNT, GRECIAN, SYRIAN, TYRIAN, &c. In the valuation of money, the Grecian *talent*, according to Dr. Arbuthnot, was equal to 60 *minæ*, or, reckoning the *mina* at £3 4s. 7d., equal to £193 15s. The Syrian *talent* in this valuation consisted of 15 Attic *minæ*; the Ptolematic of 20; the Antiochian of 60; the Euboic of 60; the Babylonic of 70; the Greater Attic of 80; the Tyrian of 80; the Egeian of 100; the Rhodian of 100; and the Egyptian of 80 *minæ*. There is another *talent* much more ancient, which Dr. Arbuthnot calls the Homeric *talent* of gold, which seems to have weighed six Attic drachms or three darics, a daric weighing very little more than a guinea.

TALÉNT, JEWISH. *Talents*, as a species of money, among the Hebrews, was sometimes used for a gold coin, the same with the shekel of gold, called also stater, and weighing only four drachms. The Hebrews reckoned by these *talents* as we do by pounds, &c. Thus a million of gold, or million of *talents* of gold, among them, was a million of shekels or nummi; the nummus of gold being the same weight with

the shekel, viz. four drachms. But the Hebrew talent weight of silver, which they called *cicar*, was equivalent to that of 3000 shekels, or 113 lbs. 10 oz. 1 dwt. 10 gr. English troy weight, according to Arbuthnot.

TALENT, ROMAN. Among the Romans there were two kinds of talents, the little and the great talent; the little was the common talent; and, whenever they say simply *talentum*, they are to be understood of this. The little talent was 60 minæ or Roman pounds; the mina or pound estimated at 100 drachmæ or denarii; it was also estimated at twenty-four great sesterces, which amounted to 60 lbs. The great talent exceeded the less by one-third part. Budæus computes, that the little talent of silver was worth £75 sterling, and the great £99 6s. 8d. sterling. The greater of gold was worth £1125 sterling.

TALESSE. See **TALASSE.**

TALETUM, a town of Laconia, on mount Taygetus, famous for its temple of Apollo. Horses were sacrificed in it. *Paus.*

TALHAIARN, a celebrated bard of Wales, who flourished in the middle of the seventh century. He composed among other poems a poetical prayer, which became a general formula among the bards.

TALIACOTIUS (Gaspar), chief surgeon to the great duke of Tuscany, was born at Bononia, in Italy, in 1553. He wrote a Latin treatise entitled *Chirurgia Nota de Cûrtis Membris*, in which he teaches the art of engrafting noses, ears, lips, &c., giving representations of the instruments and proper bandages.

TALIESSIN, the most famous of the ancient bards of Wales. He flourished in the sixth century, under princes Elphin and Urien. About eighty of his poems are preserved, and published in the *Welsh Archæology*.

TALIO, *lex talionis*, or the law of retaliation; a species of punishment, in the Mosaic law, whereby an evil is returned similar to that committed against us by another; as an 'eye for eye, tooth for tooth.' This law was first inserted in the XII. tables amongst the Romans; but afterwards set aside, and a power given to the prætor to fix upon a sum of money for the damage.

TALISMAN, *n. s.* } Gr. *τελεσμα*.—Skin-
TALISMAN'IC, *adj.* } ner. Arab. *talia az-*
man is to try fortune. A magical character. See below. The adjective corresponding.

The figure of a heart bleeding upon an altar, or held in the hand of a Cupid, has always been looked upon as *talismanic* in dresses of this nature.

Addison.

Of *talismans* and sigils knew the power,
And careful watched the planetary hour. *Pope.*

If the physicians would forbid us to pronounce gout, rheumatism, and stone, would that serve like so many *talismans* to destroy the diseases? *Swift.*

TALISMANS are magical figures cut or engraved with superstitious observations on the characters and configurations of the heavens, to which some astrologers have attributed wonderful virtues, particularly that of calling down celestial influences. The talismans of Samothrace, so famous of old, were pieces of iron formed into certain images, and set in rings; these were esteemed preservatives against all kinds of evils.

There were likewise talismans taken from vegetables, and from minerals.

TALK, *v. n. & n. s.* } Belgic *taelen*, or
TALK'ATIVE, *adj.* } from **TALE**. To speak
TALK'ATIVENESS, *n. s.* } in conversation; speak
TALK'ER, } fluently and familiarly;
TALK'Y, *adj.* } converse; prattle:
oral conversation; speech; report; rumor: talkative, loquacious: the noun substantives following correspond: talky, consisting of talk: resembling talk.

Will ye speak wickedly for God, and talk deceitfully for him. *Job xiii. 7.*

The princes refrained *talking*, and laid their hand on their mouth. *Id. xxix. 9.*

Let me *talk* with thee of thy judgments.

Ser. xii. 1.

The children of thy people still *talk* against thee. *Ezekiel.*

How can he get wisdom that driveth oxen, is occupied in their labours, and whose *talk* is of bullocks? *Eccles. xxxviii.*

If I have held you overlong, lay hardly the fault upon my old age, which in its disposition is *talkative*. *Sidney.*

Perceiving his soldiers dismayed, he forbade them to have any *talk* with the enemy.

Knolles's History of the Turks.

I will buy with you, sell with you, *talk* with you; but I will not eat with you. *Shakespeare.*

We do remember; but our argument is all too heavy to admit much *talk*. *Id.*

Keep me company but two years, Thou shalt not know the sound of thine own tongue. —Farewell; I'll grow a *talker* for this jeer. *Id.*

As God remembers that we are but flesh, unable to bear the nearer approaches of divinity, and so *talks* with us at once with Moses through a cloud; so he forgets not that he breathed into us the breath of life, a vital active spirit. *Decay of Piety.*

The greatest *talkers* in the days of peace have been the most pusillanimous in the day of temptation.

Taylor.

Hypocrites austere*ly talk*

Of purity. *Milton.*

The crystalline sphere, whose balance weighs The trepidation *talked*. *Id.*

What delight to be by such extolled, To live upon their tongues and be their *talk*, Of whom to be despised were no small praise? *Id.*

Here free from court compliances he walks, And with himself, his best adviser, *talks*. *Waller.*
Consider well the time when Petavius first began to *talk* in that manner. *Waterland.*

We will consider whether Adam had any such heir as our author *talks* of. *Locke.*

This ought to weigh with those whose reading is designed for much *talk* and little knowledge. *Id.*

I hear a *talk* up and down of raising our money, as a means to retain our wealth, and keep our money from being carried away. *Id.*

If it were desirable to have a child a more brisk *talker*, ways might be found to make him so, but a wise father had rather his son should be useful when a man, than pretty company. *Id. on Education.*

My heedless tongue has *talked* away this life.

Rowe.

I am ashamed I cannot make a quicker progress in the French, where every body is so courteous and *talkative*. *Addison.*

We call this *talkativeness* a feminine vice; but he that shall appropriate loquacity to women, may perhaps sometimes need to light Diogenes's candle to seek a man. *Government of the Tongue.*

It is a difficult task to *talk* to the purpose, and to put life and perspicuity into our discourses.

Collier on Pride.

The coxcomb bird so *talkative* and grave,
That from his cage cries cuckold, whore, and knave;
Though many a passenger he rightly call,
You hold him no philosopher at all.

Pope.

In various *talk* the instructive hours they pass,
Who gave the ball, or paid the visit last.

Id.

Learned women have lost all credit by their impertinent *talkativeness* and conceit.

Swift.

Talking over the things which you have read with your companions, fixes them upon the mind.

Watts.

Let me give for instance some of those writers or *talkers* who deal much in the words Nature or Fate.

Id.

TALK, *n. s.* } From TALC, which see. Fr.
TALK'Y, *adj.* } *talc.* A mineral: the adjective corresponding.

Venetian *talk* kept in a heat of a glass furnace, though brittle and discoloured, had not lost much of its bulk, and seemed nearer of kin to *talk* than mere earth.

Boyle.

Stones composed of plates are generally parallel, and flexible and elastic: as *talk*, cat-silver or glimmer, of which there are three sorts, the yellow or golden, the white or silvery, and the black.

Woodward on Fossils.

The *talky* flakes in the strata were all formed before the subsidence along with the sand.

Id.

TALL, *adj.* } Fr. *taille*; Ital. *taglia*;
TALL'NESS, *n. s.* } Span. *talle*; Welsh *tâl*.
High in stature; lofty; sturdy: the noun substantive corresponding.

An hideous giant, horrible and high,
That with his *talness* seemed to threaten the sky.

Spenser.

Bring word how *tall* she is.

Shakspeare. Antony and Cleopatra.

I'll swear thou art a *tall* fellow of thy hands, and that thou wilt not be drunk; but I know thou art no *tall* fellow of thy hands, and that thou wilt be drunk; but I would thou wouldst be a *tall* fellow of thy hands.

Id. Winter's Tale.

The eyes behold so many naked bodies, as for *tallness* of stature could hardly be equalled in any country.

Hayward.

Two of nobler shape,
Erect and *tall*.

Milton.

Winds rushed abroad

From the four hinges of the world, and fell
On the vext wilderness, whose *tallest* pines,
Though rooted deep as high, and sturdiest oaks,
Bowed their stiff necks.

Milton's Paradise Regained.

May they encrease as fast, and spread their boughs,
As the high fame of their great owner grows!

May he live long enough to see them all
Dark shadows cast, and as his palace *tall*!

Methinks I see the love that shall be made,
The lovers walking in that amorous shade.

Waller.

They lop, and lop, on this and that hand, cutting away the *tall*, sound, and substantial timber, that used to shelter them from the winds.

Davenant.

TAL'LAGE, *n. s.* Fr. *tailage*. Impost; excise.

The people of Spain were better affected to Philip than to Ferdinand, because he had imposed upon them many taxes and *tallages*.

Bacon's Henry VII.

TALLARD (Camillus d'Hostun), count of, a celebrated French general, born at Provence in 1652. He commanded the army on the Rhine in 1702, and in 1703 was made a marshal; when

he defeated the prince of Hesse-Cassel, and took Landau. In 1704 he was sent with an army of 40,000 men against the duke of Marlborough and prince Eugene; but was defeated and taken prisoner at the battle of Hochstet, and brought over to England, where he was detained seven years. Upon his return to Paris he was created a duke, and made secretary of state in 1726. He died in 1728.

TALLEYRAND-PERIGORD (Alexandre Angelique de) the son of the marquis de Talleyrand, and uncle of the celebrated statesman of the same name, was born at Paris in 1736. He obtained various benefices in the church early in life, and became royal almoner, and grand vicar of Verdun: before he was thirty he was appointed coadjutor of the archbishop of Rheims, whom he succeeded in 1777. Nominated a member of the second assembly of the Notables, and afterwards a deputy of the States General, he vainly endeavoured to defend the privileges of the clergy. At length he retired to Aix-la-Chapelle, and subsequently resided at Weimar and Brunswick. Louis XVIII. having invited him to Mittau, he accompanied that prince to England; and on the death of the cardinal de Montmorenci, in 1808, succeeded him as grand almoner. At the restoration he had at first great influence in ecclesiastical affairs, but his councils were afterwards neglected. In 1816 he resigned the archbishopric of Rheims, and the following year was appointed to that of Paris and made a cardinal. The execution of the concordat of 1817 meeting with obstacles, he did not take possession of his see till 1819, and the remainder of his life was devoted to the regulation of its concerns. He died October 20th 1821.

TALLIEN (Jean Lambert), one of the leaders in the French revolution, was originally a porter and then a steward, after which he became a clerk under government. In 1791 he was editor of the *Moniteur*; and about the same time was made secretary-general of the commune of Paris. During the reign of terror he did some praiseworthy actions, and M. Hue, valet-de-chambre to Louis XVI., and Madame de Stael, were indebted to him for their lives. The end of that dreadful anarchy in the downfall of Robespierre will hand the name of Tallien down to posterity with honor, when his other deeds are forgotten. He had formed an attachment for Madame Cabarus; but at this period the connexion was broken off and she was thrown into a dungeon. Robespierre, being afraid of Tallien, offered her life and liberty if she would betray him. But, though her lover had been faithless, she rejected the proposal, and sent privately this note to Tallien:—'The minister of police has announced to me that to-morrow I am to appear at the tribunal—that is to say, I am to ascend the scaffold, I dreamt last night that Robespierre was no more, and that my prison doors were opened. A brave man might have realised this dream; but, thanks to your cowardice, no one remains capable of its accomplishment.' Tallien answered—'Be as prudent as I shall prove brave; and above all be tranquil.' The next day he hurried to the tribune, and, regardless of all danger, attacked Robespierre to his face with

such eloquence that the hearers were electrified. Then, snatching a dagger from his bosom, he swore that he would bury it in the tyrant's heart if he were not publicly denounced. The moment was critical—the fate of Tallien hung on a thread—but the assembly joined him, the miscreant fell, and Madame Cabarus was saved. Tallien accompanied Buonaparte to Egypt, but died in penury at Paris, aged fifty-four, in 1820.

TALLIS (Thomas), an English musician of the sixteenth century, reckoned one of the most eminent that ever England bred. But his abilities were wholly devoted to sacred music. He is said to have been organist of the chapel royal to Henry VIII., Edward VI., Mary I., and Elizabeth. It is certain he was organist along with Bird under Elizabeth; and these two published an admired collection of Hymns for the Church Service. He composed the Morning, Evening, and Communion Services, in four parts, with the preces, responses, and litany; and several anthems. He died 23d of November 1585, and was buried in Greenwich church.

TALLOW, *n. s.* } Swed. and Dan.

TALLOWCHANDLER. } *talge*; Belg. *talk*. The grease or fat of an animal; coarse suet: the tallowchandler is the dealer in and melter of the fat.

She's the kitchen wench, and all grease; and I know not what use to put her to, but to make a lamp of her, and run from her by her own light. I warrant her rags, and the tallow in them, will burn a Lapland winter. *Shakspeare.*

The new world is stocked with such store of kine and bulls, brought hither out of Europe since the first discovery, that the Spaniards kill thousands of them yearly, for their tallow and hides only.

Heylyn

Nastiness, and several nasty trades, as tallowchandlers, butchers, and neglect of cleansing of gutters, are great occasions of a plague.

Harvey on the Plague.

Snuff the candles close to the tallow, which will make them run. *Swift.*

TALLOW, in commerce, is the fat of certain animals melted and clarified. It is procured from most animals, but chiefly from bullocks, sheep, hogs, and bears. Some kinds of tallow are used as unguents in medicine, some for making soap and dressing leather, and some for making candles. See ANATOMY, CHEMISTRY, and FAT.

TALLOW, MOUNTAIN, a mineral substance, specimens of which were lately found in a bog on the borders of Loch Fyne in Scotland. This curious mineral was first observed by some peasants on the coast of Finland in 1736; and it was afterwards found in one of the Swedish lakes. It has the color and feel of tallow, and is tasteless. It melts at 118° Fahrenheit, and boils at 290°. When melted it is transparent and colorless: on cooling it becomes opaque and white, though less so than at first. It is insoluble in water, but soluble in hot alcohol, oil of turpentine, olive oil, and naphtha, but precipitates as these liquids cool. Its specific gravity in the natural state is 0.6078, but it is then full of air-bubbles. After fusion its density is 0.983, which is something above ordinary tallow. It does not combine with alkalies nor form soap. Thus it

differs from every class of bodies known. From the fixed oils in not saponifying; from the volatile oils and bitumen in being tasteless and destitute of smell. In volatility and combustibility it resembles naphtha.—Edin. Phil. Journ. xi. 214.

TALLOW, PINEY, a concrete inflammable substance, obtained by boiling in water the fruit of the vateria Indica, a tree of the Malabar coast. It partakes of the nature of both wax and oil, and from its appearance may not inaptly be termed a tallow. It is employed in the town of Mangalore, as an external application for bruises and rheumatic pains. It melts at 97½° Fahrenheit; is generally white, sometimes yellow, and is greasy to the touch with some degree of waxiness. Specific gravity 0.926 at 60°. It is not soluble in alcohol, which takes merely two per cent. of elain. Fixed alkalies saponify it. It forms excellent candles, coming freely from the mould. Its ultimate constituents are,

Carbon	. . .	77.0 = 10 atoms
Hydrogen	. . .	12.3 = 9
Oxygen	. . .	10.7 = 1

Dr. Babington in Journal of Science, xix. 177.

TALLOW TREE. See CHINA. Sir George Staunton says that the candles made of the vegetable tallow are firmer than those made of animal tallow, and free from all offensive smell. They are not, however, equal to those of wax or spermaceti; but the latter is not within the reach of the Chinese, and the art of blanching the former is little known to them. The tallow tree has been transplanted to Carolina, and flourishes there as well as in China.

TALLY, *n. s., v. a., & v. n.* See TAILLE. Fr. *tallier*, to cut. A stick notched or cut in conformity to another stick, and used to keep accounts by: hence to suit; fit: be fitted; conform.

So right his judgment was cut fit, .
And made a tally to his wit. *Hudibras.*
So suited in their minds and persons,
That they were framed the tallies for each other:
If any alien love had interposed,
It must have been an eye sore to beholders.

Dryden.

The only talents in esteem at present are those of Exchange Alley; one tally is worth a grove of bays. *Garth.*

I found pieces of tiles that exactly tallied with the channel. *Addison on Italy.*

Nor sister either had nor brother;
They seemed just tallied for each other. *Prior.*

Have you not seen a baker's maid
Between two equal panniers swayed?

Her tallies useless lie and idle,
If placed exactly in the middle.

Id.

They are not so well tallied to the present juncture. *Pope.*

From his rug the skewer he takes,
And on the stick ten equal notches makes;
With just resentment flings it on the ground,
There take my tally of ten thousand pound. *Swift.*

The TALLY is used by bakers, brewers, &c. And this was the ancient way of keeping all accounts, one part being kept by the creditor, the other by the debtor, &c. Hence the tallier of the exchequer, whom we now call the teller

TALLY COURT, a court where the two deputy chamberlains of the exchequer and the tally-cutter attend; and a tally is generally the king's acquittance for money paid or lent, and has written on it words proper to express on what occasion the money is received.

TALLY-CUTTER, an officer in the court of exchequer, who cuts or marks the tally. See **TALLY**.

TALLY-MAN, a person that sells or lets goods, clothes, &c., to be paid by so much a-week.

TALMA (Francis Joseph), the late Roscius of the French drama, was born at Paris about the year 1770, and is said to have given the first indication of his histrionic talent when only eight years old, in an old tragedy entitled *Tamerlane*, performed by boys. But soon after his father, who had settled in London, sent for him to England; and after a few years spent at a boarding-school in Lambeth, articulated him to a surgeon. At this period his fondness for theatrical amusements introduced him to sir John Gallini, manager of an amateur French company which performed at the Hanover Square rooms, and he appeared in several comedies, especially as count Almaviva in Beaumarchais' comedy of the *Barber of Seville*. The performances of Kemble and Siddons are said to have decided Talma's taste. He returned to Paris, and, through the interest of Molé the actor, made his début on the boards of the *théâtre Français* in the part of Seide, in Voltaire's tragedy of *Mahomet*. After performing a variety of insignificant characters, accident lifted him to the summit of his profession. Chenier's tragedy of Charles IX. was put in rehearsal, when Saintfal, the principal actor, returned his part, saying, with a sneer to the author, 'give it to young Talma.' Chenier took him at his word; Talma accepted the part with delight, and devoted all his energies to the study of it, and to a strict fidelity of costume; so that the audience, equally surprised and delighted, continued to him, throughout the representation, the tumultuous approbation with which they first greeted his appearance. His greatest triumph, however, was yet to follow. Ducis had translated the *Othello* of Shakspeare; but, not daring to contend so far against French prejudices as to exhibit the murder of *Desdemona* on the stage, he had furnished a new catastrophe. Talma was bold enough to prefer the original termination, and, after considerable hesitation, resolved, with the consent of the author, to risk it. His success astonished even himself, and was most honorably rewarded. From this moment he became the paramount tragedian, and continued at the summit of his profession, by which he acquired a handsome fortune, till his death. He was generally esteemed by men of rank and talents for his powers of fascination also in private society, and was a great favorite with the emperor Napoleon. In 1825 he published 'Reflexions' on his art, which display a considerable variety of study and research. The death of Talma took place at Paris October 19th, 1826, after a distressing illness arising from an obliteration of a portion of the large intestines. Before his death he embraced his theatrical friends Jony, Arnault, and Duvilliers, and expired ejaculating the name of Voltaire!

TAL'ON, *n. s.* Fr. and Span. *talon*, of Lat. *talus*. The claw of a bird of prey.

It may be tried whether birds may not be made to have greater or longer talons.

Bacon's Natural History.

Upward the noble bird directs his wing,
And, towering round his master's earth born foes,
Swift he collects his fatal stock of ire,
Lifts his fierce talon high, and darts the forked fire.

Prior.

TALMUD is the name of two Jewish works, the Talmud of Jerusalem and the Talmud of Babylon. Each of these is composed of two parts; the Mishna, which is the text, and is common to both, and the Gemara or commentary. See **GEMARA** and **MISHNA**. The Mishna, which comprehends all the laws, institutions, and rules of life, which, besides the ancient Hebrew Scriptures, the Jews thought themselves bound to observe, was composed, according to their own unanimous testimony, about the close of the second century. It was the work of Rabbi Juda Hakkadosh, who was the ornament of the school at Tiberias, and is said to have occupied him forty years. The commentaries and additions which succeeding rabbies made were collected by Rabbi Johanan Ben Eliezer, in the fifth, sixth, or seventh century, under the name of Gemara, that is, completion; because it completed the Talmud. A similar addition was made to the Mishna by the Babylonish doctors in the sixth or seventh century. The Talmud of Babylon is most valued by the Jews; and this is the book which they mean, when they talk of the Talmud in general. An abridgment of it was made by Maimonides in the twelfth century, in which he rejected some of its greatest absurdities. The last edition of the Talmud of Babylon, printed at Amsterdam, is in 12 vols. folio. The Talmud of Jerusalem is in one large folio.

TALOOK, an Arabic word, which signifies literally attachment, connexion, dependence. In Bengal, however, where it occurs perpetually in the enumeration of the districts and subdivisions of that province contained in the institutes of Akber, it signifies a tenure of land. Hence the talook of Cashinat, the talook of Meheys the headman, the talook of Ahmed Khan, &c. See *A Dissertation concerning the Landed Property of Bengal*, by Sir Charles Rouse Boughton.

TALPA, in zoology, the mole, a genus of quadrupeds belonging to the order of feræ and class of mammalia. It has six unequal foreteeth in the upper jaw, and eight in the lower; one tusk on each side in each jaw; seven grinders on each side above, and six below. There are seven species, viz. 1. *T. aurea*, the gilded mole, or Siberian mole of Pennant, has three toes on the fore feet, with very large claws; five on the hind, with weak claws; but no tail. The snout is shorter than that of the European (No. 3); the nose naked; the head and body four inches; the fur above varied with glossy green, golden, and reddish copper color; the lower a cinereous brown. They inhabit the Cape of Good Hope and Siberia.

2. *T. cristata*, the crested mole, or *sorex cristatus* of Gmelin, has five toes on each foot; a short tail; and the nose long and surrounded at

the point with ten or fifteen short radiated tendrils forming a star; the body is thick and round, and covered with a fine short dusky fur. They feed on roots, and inhabit North America.

3. *T. Europæa*, the European mole, is the only species found in Britain. They inhabit the whole of Europe, except Ireland, where no moles are found. They are also common in the North of Asia and Africa. They chiefly frequent moist fields exposed to the sun, meadows, and gardens; through which they form subterraneous roads in every direction in search of worms, on which and the larvæ of insects they feed, and not on vegetables, though they do great damage by loosening the roots of plants. They are most active before rain, as the worms are then in motion. The penis of the male is exceedingly long in proportion; they pair and propagate in spring, the female bringing four or five young at a birth, which are placed in nests made of moss, leaves, and dried grass, under the largest hillocks of the field; these are constructed with wonderful ingenuity, consisting of an interior hillock, surrounded with a ditch, which communicates with several galleries, on purpose to carry off the moisture; and the nest is covered over with a dome of earth, like the flat arch of an oven. Moles are destroyed by a paste composed of palma christi and white hellebore, or by flooding the fields which they infest; though, in the latter case, they sometimes escape by ascending trees. This species is five inches and three-quarters in length, and its tail about one inch. It has a large head, without any external ears, and eyes so very small, and so completely hid in the fur, as to make it vulgarly believed that it has none. As they live entirely below ground, they have certainly no occasion for eyes; and as they probably find their food by the smell, which is acute, eyes may serve merely to warn them when they happen to emerge from the ground to return to their subterraneous dwelling. There are four varieties, viz. i. *T. Europæa alba*, the white mole, with fur uniformly white. ii. *T. Europæa cinerea*, the gray mole, has narrow fore paws; the fur is of a cinereous color. iii. *T. Europæa nigra*, the black mole, has fur uniformly black. iv. *T. Europæa variegata*, the variegated mole, has fur variegated with white spots.

4. *T. flava*, the yellow or American mole, has five toes on each foot, the fur is of a yellowish-brown color at the tips, and dark gray at the roots; the head is brightest; the rump dark; the belly deep brown; the feet and tail white. They inhabit North America.

5. *T. fusca*, the brown mole, the *sorex aquaticus*, or aquatic shrew, of Gmelin, has five toes on all the feet, which are palmated; the tail and feet short and white; two fore teeth in the upper, and four in the lower jaw. The head and body are five inches and a half long; the tail not an inch; the nose is slender; the upper jaw longer than the under. They inhabit North America. This and the *cristata* were formerly ranked under the genus *sorex*; but, as they have the manners and figure of the moles, they are very properly restored to this genus by Mr. Pennant.

6. *T. longicaudata*, the long tailed mole of Pennant, has five toes on all the feet, which are broad, naked, and palmated; the fore feet have

strong short claws; the hind feet long and slender ones, and are scaly. The head and body are from four to six inches long; the tail two, sometimes three. They inhabit North America.

7. *T. rubra*, the red American mole, has three toes on the fore feet, four on the hind, and a short tail. It is of a pale-red color, and in form resembles the European, but is larger, and the root of the tail is thicker. They inhabit America.—Kerr's Animal Kingdom, vol. i. p. 199—203.

TALTHYBIUS, a celebrated herald in the Grecian camp, during the Trojan war, the friend and minister of Agamemnon, who sent him to bring away Briseis from Achilles. He died at Elgium, in Achaia. Hom. Il. i. v. 320, &c., Paus. vii. c. 23.

TALUD, or TALUS, in architecture, the inclination or slope of a work; as of the outside of a wall, when its thickness is diminished by degrees, as it rises in height, to make it the firmer.

TALUS, in fortification, the slope of a work, whether of earth or masonry.

TALUS, in history, partly fabulous, the nephew of Dædalus, and, like his uncle, a great mathematical genius, having invented the saw, compasses, and other mechanical instruments. But this merit occasioned his murder. See Dædalus. The poets fabled that he was turned into a partridge.

TAMANDUA, or TAMANOIR, in zoology. See MYRMECOPHAGA.

TAMAR, in Scripture history, a name common among the Israelitish women, as, 1. The wife of Er and Onan, Judah's sons, and mother of Pharez and Zarah by himself; 2. A daughter of David and full sister of Absalom, ravished by her brother Amnon. See ABSALOM and AMNON. 3. A daughter of Absalom.

TAMARACA, a province of Brasil, bounded north by the province of Paraíba, and south by that of Olinda, east by the sea, and west by the country of the Indians. It is seven leagues along the coast, but thirty or forty in the interior of the country, and takes its name from an island which it has opposite to it near the continent, producing large quantities of Brasil wood, cotton, cocoa-nuts, sugar, melons, citrons, &c., besides a good deal of timber for fuel and other purposes. It is about nine miles in length, three in breadth, and about twenty-two in circuit. It has a commodious haven on the south side, and good fresh water. The entrance into the port is by a channel of between fifteen and sixteen feet water, commanded by a castle, built on an eminence, and formerly taken by the Dutch. The French had formerly a canton or settlement on this coast, but the Portuguese obliged them to evacuate it. The capital, called *Nostra Senhora de Conceicao*, or *da Tamaraca*, stands at the entrance into the river of the latter name; and near it is a small castle with a redoubt; about four miles north of the mouth of the river is the famous point denominated *Punta Pedro*.

TAMARACA, the capital of the above district, is situated on the top of a mountain, and has a magnificent parish church. Fourteen miles north of Olinda, and sixty-four south of Paraíba. Long. 35° 6' W., lat. 7° 59' S.

TAMARIL, a town of Spain in Catalonia; two miles north-east of Tarragona.

TAMARIND, *n. s.* Lat. *tamarindus*; Pers. *tamar*. A fruit.

Lenitives are cassia, *tamarindus*, manna.
Wiseman's Surgery.

 Lay me reclined

Beneath the spreading *tamarind*, that shakes,
Fanned by the breeze, its fever cooling fruit.

Thomson.

The flower of the *tamarind* tree consists of several leaves, which are so placed as to resemble a papilionaceous one in some measure; but these expand circularly, from whose many-leaved flower-cup rises the pointal, which afterward becomes a flat pod, containing many flat angular seeds surrounded with an acid blackish pulp.

Miller.

TAMARIND TREE, or **TAMARINDUS**, in botany, a genus of plants arranged by Linnæus under the class of triandria and order of monogynia; but Woodville, Schreber, and other late botanists, have found that it belongs to the class of monadelphina and order of triandria. In the natural system it is ranked under the lomentaceæ. There is only one species, viz.

T. Indica, a native of both Indies, of America, of Arabia, and Egypt. It was cultivated in Britain before 1633. It rises to thirty or forty feet, sending off numerous large branches, which spread to a considerable extent, and have a beautiful appearance; the trunk is erect, and covered with rough bark of a grayish or ash color; the leaves are small and pinnated, and of a yellowish green color; the flowers resemble the papilionaceous kind, and grow in lateral clusters; the calyx consists of four leaves, and the corolla of three petals, of a yellowish hue, and beautifully diversified with red veins; the fruit is a pod of a roundish compressed form, from three to five inches long, containing two, three, or four seeds, in a dark pulpy matter. The flowers appear, according to Jacquin, in October and November; but, according to Dr. Wright, during the whole of June and July. The pulp of the tamarind, with the seeds connected together by numerous tough strings or fibres, are brought to us freed from the outer shell, and commonly preserved in syrup. The fruit produced in the East Indies is more esteemed than that of the West, and is distinguished by the greater length of the pods, and the pulp being dryer and of a darker color. This fruit, the use of which was first learned of the Arabians, contains a large proportion of acid, and is therefore not only employed as a laxative, but also for abating thirst and heat in various inflammatory complaints, and putrid disorders, especially those of a bilious kind; in which the cathartic, antiseptic, and refrigerant qualities of the fruit have been found equally useful. When intended merely as a laxative, it may be joined with manna, or purgatives of a sweet kind, by which it is rendered safer and more effectual. Three drachms of the pulp are usually sufficient to open the body; but, to prove moderately cathartic, one or two ounces are required. It is an ingredient in electuarius e cassia, and electuarius e senna or lenitive electuary. - See **MATERIA MEDICA**, and **PHARMACY**.

The pulp consists, according to Vanquelin, of

bitartrate of potash 300, gum 432, sugar 1152, jelly 576, citric acid 864, tartaric acid 144, malic acid 40, feculent matter 2880, water 3364; in 9752 parts.

TAMARIS, a river of Spain. Lemp.

TAMARISK, *n. s.* Lat. *tamarice*.

The flowers of the *tamarisk* are rosaceous. *Miller.*

Tamarisk is a tree that grows tall, and its wood is medicinal.
Mortimer's Husbandry.

TAMARISK, **TAMARIX**, in botany, a genus of plants belonging to the class of pentandria, and order of tryginia; and in the natural system ranging under the thirteenth order, succulentæ. The calyx is quinquepartite; the petals are five; the capsule is unilocular and trivalvular, and the seeds pappous. There are only two species known: viz.—1. *T. Gallica*, French tamarisk, which grows upon the sea coasts. When burnt it affords sulphate of soda. See **CHEMISTRY**, Index. ii. *T. Germanica*, German tamarisk.

TAMARUS, a mountain of Epirus. Strabo.

TAMARY. See **SOCOTORA** and **TAMARA**.

TAMASA, a river of Asia, in Mingrelia.

TAMASCAL, the name given in California to a kind of sand-bath employed by the natives in the cure of the venereal disease. It is prepared by scooping a trench in the sand, two feet wide, one foot deep, and of a length proportioned to the size of the patient; a fire is then made through the whole extent of it, as well as upon the sand which was dug out of the hollow. When the whole is thoroughly heated, the fire is removed, and the sand stirred about, that the warmth may be equally diffused. The sick person is then stripped, laid down in the trench, and covered up to his chin with heated sand. In this position a very profuse sweat soon breaks out, which gradually diminishes according as the sand cools. The patient then rises and bathes in the sea, or the nearest river. This process is repeated till a complete cure is obtained. While the patient is undergoing the operation of the tamascal, he drinks a considerable quantity of a warm sudorific, prepared by the decoction of certain herbs, chiefly of the shrub called by the Spaniards *Gouvernante*.

TAMASEA, a plain of Cyprus, sacred to Venus. Plin. 5.

TAMBARINE', *n. s.* Fr. *tambourin*. A tambor; a small drum. It should be **TAMBOURIN**, which see.

Calliope with muses moe,

Soon as thy oaken pipe began to sound,

Their ivory lutes and *tambarines* forego.

Spenser's Pastorals.

TAMBOV, a large province of European Russia, lying to the west of those of Penza and Saratov, between lat. 51° 30' and 55° 20' N., and long 39° 40' and 43° 40' E. Its territorial extent is calculated at about 21,000 square miles, and its population at 1,135,000. It is level, and occupied by extensive steppes. Many tracts are woody and marshy, but in general a sandy soil pervades the north, and a black and fertile mould the south. It is well watered both by rivers and small lakes. The winter is severe, but in summer the heat is such that the Polish cochineal and Spanish fly are common. The steppes contain various beasts of game, and the

mineral products are iron, sulphur, and saltpetre. In 1808, on making a statistical survey, there were found in this government twenty-seven large manufacturing establishments, and the capital employed in trade was returned at £500,000 sterling. The province is divided into twelve circles.

TAMBOV, a considerable town; the capital of the above government, is situated on the river Zna. It is the see of a Greek bishop; with a seminary, gymnasium, and schools for the families of the better classes. It has a large monastery, in which there are two churches; and the town contains fourteen other churches. It has manufactures of woollens, canvas, linen, and alum, and a considerable carrying trade; but the chief employment of the inhabitants is agriculture. Inhabitants 10,700. 286 miles south-east of Moscow.

TAMBOUR, in architecture, a term applied to the Corinthian and Composite capitals, as bearing some resemblance to a drum, which the French call tambour. Some choose to call it the vase, and others campana or the bell.

TAMBOUR is also used for a little box of timber work, covered with a ceiling, withinside the porch of certain churches; both to prevent the view of persons passing by, and to keep off the wind, &c.; by means of folding doors, &c.

TAMBOUR also denotes a round course of stone, several whereof form the shaft of a column, not so high as a diameter.

TAMBOUR, in the manufactures, is a species of embroidery. The tambour is an instrument of a spherical form, upon which is stretched, by a string and buckle, a piece of linen or thin silken stuff; which is wrought with a needle of a particular form, and by means of silken or gold and silver threads, into leaves, flowers, or other figures.

TAMBOURIN, a tabor or small drum: also a dance performed on the French stage. The air is lively and the movements are quick. See MUSIC.

TAME, *adj.* & *v. a.* } Sax. *tæme*; Belg. }
 TAME'ABLE, *adj.* } *tæm*; Dan. *tam*. Sub- }
 TAME'LY, *adv.* } dued; gentle; domes- }
 TAME'NESS, *n. s.* } tic; crushed; depress- }
 TAME'R. } ed: to reduce from }
 wildness; reclaim; make gentle: the adjective, adverb, and noun substantives corresponding.

If you should need a pin,
 You could not with more *tame* a tongue desire it.
Shakspeare.

A most poor man, made *tame* to fortune's blows,
 Who, by the art of known and feeling sorrows,
 Am pregnant to good pity. *Id. King Lear.*

If the heavens do not their visible spirits
 Send quickly down to *tame* the offences,
 Humanity must perforce prey on itself. *Id.*

A puling cuckold would drink up
 The lees, and dregs of a flat *tamed* piece.
Shakspeare.

True obedience, of this madness cured,
 Stoop *tame*ly to the foot of majesty. *Id. Henry IV.*
 They cannot *tame*

Or overcome their riches; not by making
 Baths, orchards, fish-pools, letting in of seas
 Here, and then there forcing him out again.

Ben Jonson.

Ganzas are supposed to be great fowls of a strong fight, and easily *tameable*; divers of which may be so brought up as to join together in carrying the weight of a man. *Wilkins.*

Praise him, each savage furious beast,
 That on his stores do daily feast,
 And you, *tame* slaves of the laborious plough,
 Your weary knees to your Creator bow.

Roscommon.

A race unconquered, by their clime made bold,
 The Caledonians, armed with want and cold,
 Have been for ages kept for you to *tame*. *Waller.*

What courage *tame*ly could to death consent,
 And not by striking first the blow prevent? *Dryden.*
 Has he given way?

Did he look *tame*ly on, and let them pass? *Addison.*
 Thales the Milesian said, That of all wild beasts
 a tyrant is the worst, and of all *tame* beasts a flat-
 terer. *Id.*

Such a conduct must appear rather like *tameness*
 than beauty, and expose his authority to insults.

Rogers.

He, great *tamer* of all human art,
 Dulness! whose good old cause I yet defend. *Pope.*
 Can you love and reverence your prelate, whom
 you *tame*ly suffer to be abused? *Swift.*

TAMERLANE, or TIMUR BEK, a celebrated prince and conqueror. As he very early exhibited uncommon courage, he had at the age of twenty-five attained the highest dignities. He spent nine years in different countries, travelling for improvement. He conquered the three great empires of Persia, India, and Egypt; plundered Bagdad, Delhi, Cairo, and other rich cities; and took prisoner Bajazet I. emperor of the Turks; so that his power, riches, and magnificence became immense. There remain vast monuments of his grandeur in the cities, towns, castles, and walls, which he built; in the rivers and canals which he dug, as well as in the bridges, gardens, palaces, hospitals, mosques, and monasteries, which he erected in the various parts of Asia. Timur, according to the historian Arabshah, was very corpulent and yet tall. He had a large forehead, and a big head. His countenance was agreeable, and his complexion fair. He had a large beard, was very strong, and well limbed; had broad shoulders, thick fingers, and long legs. His constitution was amazingly vigorous; but he was maimed in one hand, and lame of the right side. His eyes appeared full of fire; his voice was loud and piercing; and, when far advanced in years, his understanding was sound, his body vigorous and robust. He died on the first of April 1405, aged seventy-one, in the thirty-sixth year of his reign. See BAGDAD, INDIA, MOGULS, PERSIA, and SYRIA.

TAMESIS, in ancient geography, a river of South Britain, now called the Thames. *Cæs. de Bel. Gal. v. c. ii.*

TAMMEAMEA, or TAMAHAMA, king of the Sandwich isles, in the Pacific Ocean, who at the death of Captain Cook, in 1780, had arrived at manhood, but had no concern in that event. Tirriboo, the king of Owhyhee, the largest of the Sandwich Islands, having offended his principal officers, he was put to death, and Tammeamea was chosen to succeed him. He soon showed extraordinary talents for his situation, and it was a part of his policy to encourage the settlement of Europeans in his dominions.

When Vancouver visited Owhyhee, Tammeamea put himself under the protection of that officer, as the representative of the king of Great Britain; and, as the price of his submission, he was assisted in building a fine vessel. Tammeamea afterwards formed a fleet, with which he conquered the adjoining islands, and traded to China. He subsequently erected a fort on the island of Vahou, and obtained from the Russians some artillery; while, by encouraging the trading of his subjects with navigators, he added to his own wealth and importance as well as that of his people. This enterprising monarch died in March, 1819. Rhio Rhio, the son and successor of Tammeamea, having made a visit to this country, together with his queen, in 1824, both their majesties died in London, after a few months' residence.

TAMPER, v. a. Derived by Skinner from *Lat. tempto*: by others considered as a frequentative of *tempt*. To try in a meddling way; meddle; be busy with physic; practise secretly.

That key of knowledge, which should give us entrance into the recesses of religion, is by so much *tampering* and wrenching made useless.

Decay of Piety.

Others *tampered*

For Fleetwood, Desborough, and Lambert.

Hudibras.

'Tis in vain

To *tamper* with your crazy brain,

Without trepanning of your skull

As often as the moon's at full.

Id.

'Tis dangerous *tampering* with a muse,

The profits small, and you have much to lose:

For, though true wit adorns your birth or place,

Degenerate lines degrade the attained race.

Roscommon.

He tried washes to bring him to a better complexion, but there was no good to be done; the very *tampering* cast him into a disease. *L'Estrange.*

TAMTAM, a flat drum used by the Hindoos, resembling a tabor, but it is larger, and sounds louder.

TAMUS, black briony, in botany, a genus of plants belonging to the class of diccia, and order of hexandria; and in the natural system ranging under the eleventh order, sarmantaceæ. The male and female flowers are both sexpartite; there is no corolla; the style is trifid; the berry is trilobular and inferior, and contains two seeds. There are only two species known:—1. *T. communis*, the common black briony; is a native of England, but has not been observed growing wild in Scotland. It has a large root, which sends forth several long slender stems: the leaves are large, heart-shaped, dark green, and grow on long foot-stalks: the flowers are greenish, and the berry red. It flowers from May to August, and is common in hedges. 2. *T. elephantipes* is a native of the Capé of Good Hope, and was first described by L'Heritier.

TAMWORTH, a borough and market-town, partly in Staffordshire and partly in Warwickshire, at the conflux of the rivers Tame and Anker, near the great navigable canal, eight miles south-east of Litchfield, and 114 north-west of London. The church is an ancient irregular building, containing several curious monuments; and the town is large and well-built, and has

two bridges. In the town are places of worship for dissenters, a hospital, and a grammar-school. It is governed by two bailiffs, being one for each county: twenty-four burgesses, town-clerk, &c., with a high steward, recorder, and under steward. It was first incorporated by queen Elizabeth, and returns two members to parliament, one for each part of the town, the number of voters being about 250. The returning officers are the bailiffs. The town has a considerable manufacture of narrow cloths, and is noted for good ale. Calico-printing and tanning are now the principal trades carried on here. Here are two banking houses. Tamworth-castle is the seat of the earl of Leicester. Market on Tuesday. Fairs, May 4th, July 26th, and October 24th. It is a curacy.

TAN, v. a. *Fr. tanner*; *Belg. tannem*; *Arm. tann*, oak; *Teut. tan*, the fir. To impregnate or imbue with bark; imbrown, particularly by the sun.

His face all *tanned* with scorching sunny ray,

As he had travelled many a summer's day

Through boiling sands of Araby and Ind. *Spenser.*

Like sun-parched quarters on the city gate,

Such is thy *tanned* skin's lamentable state. *Donne.*

A brown for which heaven would disband

The galaxy, and stars be *tanned*. *Cleveland.*

A human skull covered with the skin, having been buried in some limy soil, was *tanned* or turned into a kind of leather. *Grew's Museum.*

Black cattle produce tallow, hides, and beef; but the greatest part of the hides are exported raw for want of bark to *tan* them. *Swift.*

They sell us their bark at a good price for *tanning* our hides into leather. *Id. Miscellanies.*

Tanners use that lime which is newly drawn out of the kiln, and not slacked with water or air. *Moxon.*

TAN, the bark of the oak after it has been ground and used by the tanner. The smaller sort is generally made up in little square cakes called turf, and sold for firing. The coarser sort is sometimes dried in the sun, and used by bakers for heating their ovens, &c., but its chief use is for hot-beds, to raise pine apples and other plants. William III. introduced the use of it from Holland, for raising orange trees; after which it was discontinued till about 1719, when ananas were first brought into England. It came into general use, and has ever since been much used by gardeners for forcing, &c., by its strong and lasting fermentation. The smaller the tan, the quicker it heats; but the larger sort acquires heat more gradually and retains it longer: gardeners therefore use the one or the other, or a mixture of both, according to the purpose for which it is wanted. It is some time after the tan comes out of the pit before it begins to heat; but, having lain a week or two, it ferments, and, if put into hot-beds properly prepared, will retain a moderate heat for three or four months. When useless for the hot-house it is still an excellent manure

TAN is sometimes, though improperly, used for the bark itself, which is the chief ingredient in the tanning of leather. Oak bark, on account of its great astringency and gummy resinous properties, is preferred to all other substances for the purpose of tanning, as it not only preserves the

leather from rotting, but also, by condensing the pores, renders it impervious to water. See TANNING.

TAN, in chemistry, is a substance found in most vegetables, which, not having hitherto been resolved into component parts, is therefore considered as simple.

TANA, a large river of Lapland, forming the boundary between Russia and Sweden for 150 miles. It traverses part of Finmark, and falls into the Arctic Ocean in lat. 71° N., long. 31° 30' E., at a gulf to which it gives name. A large quantity of salmon is caught here

TANACETUM, tansy, in botany, a genus of plants belonging to the class of syngenesia, and order of polygamia superflua; and in the natural system ranging under the forty-ninth order, compositæ. The receptacle is naked; the pappus somewhat emarginated; the calyx imbricated and hemispherical; the florets of the radius are trifid, and scarcely distinguishable. Gmelin has enumerated seven species, of which only one is a native of Britain, viz. *T. vulgare*, common tansy, grows three or four feet high; the leaves are bipinnated and serrated; the flowers yellow, and terminate the branches in flat umbels. It is found on the borders of fields and dry banks; it abounds at Wark, and Ford-castle near Kelso; on the side of Gareloch on the west coast of Ross-shire; and in Breadalbane. It flowers generally in August. There is a variety with curled leaves, called curled tansy. It has a bitter taste, and an aromatic smell disagreeable to many people. It is good for warming and strengthening the stomach; the young leaves are therefore used as an ingredient in puddings, &c. It is rarely used in medicine, though extolled as a good emmenagogue. A drachm of the dried flowers has been found beneficial in hysteric disorders arising from suppression. The seeds and leaves were formerly in esteem for destroying worms in children, and are reckoned good in colics and flatulencies. In some parts of Sweden and Lapland, a bath with a decoction of tansy is used to assist parturition. See MATERIA MEDICA.

TANÆCIUM, in botany, a genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the twenty-fifth order, putamineæ. The calyx is monophyllous, tubulated, truncated, and entire; the corolla long, monopetalous, and white; the tube cylindrical; the limbi erect, spreading, and nearly equal: the fruit a berry covered with a thick bark, large, oblong, internally divided into two parts; in the pulp are contained a number of seeds. There are only two species, viz. 1. *T. jaroba*, and 2. *T. parasiticum*, both natives of Jamaica. They grow by the sides of rivers, and climb on trees and bushes. This genus is omitted by Mr. Lee.

TANAGER, in ancient geography, a river of Italy, in Lucania, remarkable for its beautiful cascades and meanders, through a fine picturesque country. Virg. Geor. iii. v. 151. It is now called Negro.

TANAGRA, an ancient town of Bœotia, near the Euripus, between the Asopus and Thermodon, famous for cock-fighting.

TANAGRA TANAGER, in ornithology, a genus of

birds belonging to the order of passeræ. The beak is conical, acuminate, emarginated almost triangular at the base, and inclining a little towards the point. Dr. Latham has described forty-four species, all of which are of foreign extraction.

TANDY (James Napper), born in Ireland in 1757, a merchant at Dublin, who, being an enemy to the ascendancy of England, attempted to bring about a revolution. In 1791 he published a plan of reform, and was appointed secretary of a Catholic association, though himself a Protestant dissenter. He was also nominated colonel of the volunteers of Dublin; but rendered himself so obnoxious to the government, that to avoid being arrested he fled to France. Here the executive directory gave him a commission as general of brigade in an expedition against Ireland, in August, 1798, under general Rey. On its failure he took refuge at Hamburg; but, being delivered up to the English minister, he was taken to Ireland, tried for high treason, and received sentence of death. But the judgment was not executed, and, being liberated after the peace of Amiens, he went to France, and died at Bordeaux, in August, 1803.

TANETUM, an ancient town of Italy, in Mutina, now called Tonedo.

TANFANÆ LUCUS, a sacred grove in Germany, in the country of the Marsi, between the Ems and Lippe. Tac. An. i. c. 51.

TANG, *n. s.* & *v. n.* Dut. *tanghe*, acrid; Lat. *tango*. A strong taste; taste left in the mouth: obsolete. To ring with (for twang.)

Be opposite with a kinsman, surly with thy servants; let thy tongue *tang* arguments of state; put thyself into the trick of singularity.

Shakspeare. Twelfth Night.

She had a tongue with a *tang*,
Would cry to a sailor, Go hang. *Id. Tempest.*

There is a pretty affectation in the Alleman, which gives their speech a different *tang* from ours.

Holder.

Sin, taken into the soul, is like a liquor poured into a vessel; so much of it as it fills it also seasons; so that although the body of the liquor should be poured out again, yet still it leaves that *tang* behind it.

South.

It is strange that the soul should never once recalc over any of its pure native thoughts, before it borrowed any thing from the body; never bring into the waking man's view any other ideas but what have a *tang* of the cask, and derive their original from that union.

Locke.

There was not the least *tang* of religion, which is indeed the worst affectation in any thing he said or did.

Atterbury.

TANGENT, *n. s.* } Fr. *tangent*; Lat. *tan-*
TANGIBLE, *adj.* } *gens.* For the definition of tangent see below: tangible, perceptible to the touch.

Tangible bodies have no pleasure in the consort of air, but endeavour to subact it into a more dense body.

Bacon.

By the touch, the *tangible* qualities of bodies are discerned, as hard, soft, smooth.

Locke.

Nothing in this hypothesis can retain the planets in their orbits, but they would immediately desert them and the neighbourhood of the sun, and vanish away

in *tangents* to their several circles into the mundane space.

Bentley's Sermons.

TANGENT OF AN ARCH is a right line drawn perpendicularly from the end of a diameter passing to one extremity of the arch, and terminated by a right line drawn from the centre through the other end of that arch, and called the secant. See **GEOMETRY**.

TANGIER, a celebrated sea-port of Fez, in Morocco, is situated on the straits of Gibraltar, a few miles to the east of cape Spatel. It was known under the name of Tingis or Tinja to the Romans, who took it under Sertorius. On the invasion of the Saracens, it was surrendered to them by count Julian. In modern times Tangier has been a subject of eager contest between the Moors and Portuguese. In 1437 it was besieged by prince Ferdinand; but his army was defeated, and capitulated. In 1471 Alonzo of Portugal succeeded in obtaining possession of it; and about two centuries after, in 1662, it became the property of England, being ceded to Charles II. as a marriage portion with the princess Catharine of Portugal. The English, however, abandoned it in 1684. Tangier became afterwards a distinguished station of piracy, for which its situation at the mouth of the straits gave it great advantages; but the disuse of this nefarious practice has greatly diminished its importance. It now subsists chiefly by supplying the British garrison of Gibraltar with cattle and vegetables, permission for which purpose was given by Muley Ismael, the grandfather of the present emperor. The bay is encumbered by the ruins of the mole and fortification, and is not very safe during winter in westerly winds. The best anchorage is at the eastern point. There are still some batteries facing the bay: 108 miles N. N. W. of Fez, and thirty-eight W. S. W. of Gibraltar. Long. 5° 50' W., lat. 35° 42' N.

TANGLE, *v. a., v. n., & n. s.* See **ENTANGLE**. To implicate; knit together; ensnare; entrap; embroil: be entangled: a tangle is a knot of interwoven or complicated things.

She means to *tangle* mine eyes too,
'Tis not your inky brows, your black silk hair,
Your bugle eye-balls, nor your cheek of cream.

Shakespeare.

I do, quoth he, perceive
My king is *tangled* in affection to
A creature of the queen's, lady Anne Bullen. *Id.*
You must lay lime to *tangle* her desires
By wailful sonnets, whose composed rhimes
Shall be full fraught with serviceable vows. *Id.*

When my simple weakness strays,
Tangled in forbidden ways,
He, my Shepherd! is my guide,
He's before me, on my side. *Crashaw.*

He leading swiftly rowled
In *tangles*, and made intricate seem strait,
To mischief swift. *Milton's Paradise Lost.*

Now ly'st victorious
Among thy slain self-killed,
Not willingly, but *tangled* in the fold
Of dire necessity. *Id. Agonistes.*

With subtle cobweb cheats,
They're caught in knotted law-like nets;
In which when once they are entangled,
The more they stir, the more they're *tangled*.
Hudibras.

TANGROLIPIX, sultan of the Turks, in the eleventh century, a barbarous but not ungenerous conqueror, and the first of the Turks who made inroads upon the Eastern empire. He and his nephew, Cutlu-Moses, ravaged Iberia. Tangrolpix also conquered Persia in 1030, and founded a new dynasty of Turkish sultans, who reigned there for a century. See **PERSIA**.

TANJORE. A district of the Southern Carnatic, Hindostan, situated between 10° and 12° of N. lat. To the north it is bounded by the Cauvery; on the south by the sea; to the east it has also the sea; and on the west Trichinopoly and the polygar's territory.

This principality is entitled to the second rank among the provinces of Hindostan for agriculture and valued rent, the first being assigned to the district of Burdwan in Bengal. For the purposes of irrigation, prodigious mounds have been raised at Coilady to prevent the waters of the Cavery from rejoining those of the Coleroon after they have separated near Trichinopoly. From this southern branch of the river canals are conducted in all directions, which, by means of embankments and reservoirs, are diverted into every field, and fertilize a tract of country from Devicotta to Point Calymere, which would otherwise remain a barren sand. The inhabitants of this district are uncommonly industrious and expert in husbandry; there is consequently but a very small proportion of waste land compared with what is seen in some of the neighbouring territories. The dry and wet cultivation are nearly equal, being about fifty per cent. each.

It appears that, in 1807, the province consisted of 5873 townships. Of this number there are 1807 townships, in which one individual holds the whole undivided lands; 2202 of which the property is held by several persons having their distinct and separate estates; and 1774 the landed property, in which is held in common by all the Meerassdars, or proprietors of the village, who contribute labor, and receive a share of the crop in the proportion of their respective properties.

The principal articles exported to Madras are indigo, cocoa nuts, rice, grain, paddy, lamp-oil, with some piece goods. The remaining articles, from their description, appear to have been first received from the eastward, Ceylon, or the Malabar coast, and afterwards sent to Madras. These consist of betel nut, tin, pepper, tortoise-shell, benjamin, arrack, Trincomale wood, and hing. The imports into this province from Madras are small in quantity and value, and are composed chiefly of articles for the European troops and residents, with some iron hoops, camphor, raw silk, silk piece goods, anchors, iron of various sorts, gunnies, planks, and long pepper-roots. The sea-ports of most commerce are Tranquebar, Nagore, Negapatam, Carical, and Devicotta.

The Hindoo religion has been preserved in considerable splendor here, and the ancient places of worship, with their vast endowments, remain untouched. In almost every village there is a pagoda with a lofty gateway of massive architecture, where a great number of Brahmins are maintained; and on all the great roads are

choultries, built for the accommodation of pilgrims. The Brahmins are here the chief holders of land, and perform almost every office of husbandry, except holding the plough. They are all extremely loyal to the British, who grant 45,000 pagodas annually for the support of the poorer temples.

In remote times Tanjore was distinguished geographically by the name of Chola Desa, from whence originated by several corruptions the word Coromandel, and in native manuscripts its sovereign is still designated the Cholia rajah. The present race are descended from Eccojee, a Mahratta chief (the brother of Sevajee), who, in A. D. 1675, conquered the city and province, which have been retained by the same dynasty ever since, the Mahratta being the proper language of the Tanjore court. The expedition of the British troops into Tanjore, in 1749, was the first warfare in which they were engaged against the forces of a native prince; and it proved unsuccessful as to its main object, the restoration of a deposed rajah of Tanjore, who had applied for assistance to the governor of Fort St. David. Sersajee, the present rajah, is the adopted son of Tuljajee, who died A. D. 1786, and was carefully educated under the celebrated Danish missionary Mr. Schwartz; yet he continued a staunch adherent to the Brahminical doctrines and superstitions. In every other respect he is a man of liberal sentiments, and particularly indulgent to the Danish missionaries who live in his country. While yet an independent prince he protected their schools, and extended his kindness to the Roman Catholics also, who, in 1785, were estimated at 10,000 persons.

In 1799 the territory of Tanjore was subjected by treaty to the British authority; on this event the rajah reserved to himself several palaces, the Tranquebar tribute of 2000 chuckrums, a clear allowance of one lack of rupees annually, and one-fifth of the surplus revenues after payment of the civil and military disbursements, which amounts to nearly twice as much more. He was allowed, as a particular favor, to retain the two forts of Tanjore, which he keeps in excellent repair, and garrisoned with 1500 men. The province now forms one of the districts of the Madras presidency, and the arrangement has proved equally advantageous to the inhabitants and to the British.

TANJORE. A city in the Southern Carnatic, the capital of the above district, comprehends two fortresses, both of which are given up to the rajah; but, on the exigence of war, the British have a right to re-occupy them. The small fort is a mile in circumference, very strong, and in good repair. The walls are lofty, and built of large stones, and on the corners of the ramparts are cavaliers. The ditch, which is broad and deep, is cut out of the solid rock, and has a well formed glacis. It joins on one side to the large fort where the rajah resides, which is fortified in a similar manner. In the small fort is the celebrated pagoda, the chief building of which is perhaps the finest specimen of the pyramidal temple in Hindostan. Within is a bull carved from a block of black granite, an excellent example of Hindoo sculpture. From one of the

cavaliers there is a beautiful view. The pagoda forms the foreground; then appears the large fort with the rajah's palace and temples, behind which a rich country is seen covered with rice fields and clumps of trees, and beyond all a chain of lofty mountains. The river Cavery here is at the highest when the periodical rains prevail in Mysore. In early ages this was the great seat of learning in the South of India, and here the almanacs were framed, according to which the year 1800 of the Christian era corresponds with the year 1722 of Salivahanam, and the 4901 of the Cali Yug; which reckoning differs one year in the former era, and seven in the latter from that used in Karnata. The British were repulsed from before Tanjore in A. D. 1749, and it was besieged without success by M. Lally in 1758. Travelling distance from Madras, 205 miles; from Seringapatam, 237; and from Calcutta 1235 miles.

TANIS, in ancient geography, a large lake of Egypt, now called Menzaleh. See MENZALEH.

TANIS, an ancient city of Egypt, seated near the lake, on one of the eastern mouths of the Nile.

TAN'IST, *n. s.* } An Irish word. Erse *an*
TAN'ISTRY. } *taanister*. The holder of a life estate: tanistry corresponding. Obsolete.

Presently after the death of any of their captains they assemble themselves to chuse another in his stead, and nominate commonly the next brother; and then next to him do they chuse next of the blood to be *tanist*, who shall next succeed him in the said captainry.

Spenser on Ireland.

The Irish hold their lands by *tanistry*, which is no more than a personal estate for his life-time that is *tanist*, by reason he is admitted thereunto by election. *Id.*

If the Irish be not permitted to purchase estates of freeholds, which might descend to their children, must they not continue their custom of *tanistry*? which makes all their possessions uncertain.

Davies on Ireland.

By the Irish custom of *tanistry*, the chieftains of every country, and the chief of every sept, had no longer estate than for life in their chieferies; and, when their chieftains were dead, their sons or next heirs did not succeed them, but their *tanists*, who were elective, and purchased their election by strong hand. *Id.*

TANK, in the language of Hindostan, is a place enclosed for receiving and retaining the rain. During the periodical rains the tanks are filled, and thus in the dry season furnish water for the rice fields and cattle. Some of them are of great extent, measuring 300 or 400 feet on the side; they are of a quadrangular form, and lined with granite, descending in regular steps from the margin to the bottom.

TANK, *n. s.* Fr. *tanque*. A large cistern or bason.

Handle your pruning-knife with dexterity; go tightly to your business; you have cost me much, and must earn it; here's plentiful provision, rascal; sallading in the garden, and water in the tank; and, in holy days, the licking of a platter of rice when you deserve it.

Dryden's Don Sebastian.

TANK'ARD, *n. s.* Fr. *tanquard*; Belgic *tankaerd*. A large vessel with a cover, for strong drink.

Hath his *tankard* touched your brain
Sure they're fallen asleep again. *Ben Jonson.*

Marius was the first who drank out of a silver *tankard*, after the manner of Bacchus. *Arbutnot.*

When any calls for ale, fill the largest *tankard* cup top full. *Swift.*

TANNA, an island in the South Pacific, one of the New Hebrides, was discovered by captain Cook in the year 1774; about twenty-two miles in length, and ten in breadth. The inhabitants would not suffer Cook, or any of his company, to advance far into the island. The produce, as far as could be seen, is bread-fruit, plantains, coconuts, a fruit like a nectarine, yams, tarra, a sort of potato, sugar-cane, wild figs, a fruit like an orange, which is not eatable, and some other fruits and nuts. Hogs did not seem to be scarce, but they saw not many fowls. Land birds are not more numerous than at Otaheite; but they saw some small birds with a very beautiful plumage, which they had never seen before, and a great variety of trees and plants. The people are of the middle size, but few.

TANNER (Dr. Thomas), an English prelate and celebrated antiquarian, born in 1674. He was admitted of Queen's College, Oxford. In 1697 he was chosen fellow. In 1722 he was made archdeacon of Norwich; and in 1731 bishop of St. Asaph. He died at Oxford in 1735; and after his death was published an elaborate work, said to have employed him for forty years, entitled *Bibliotheca Britannica Hibernica*, sive, de *Scriptoribus qui in Anglia, Scotia, et Hibernia, ad sæculi XVII. initium floruerunt, &c.*

TANNIN, in chemistry and the arts, one of the immediate principles of vegetables, was first distinguished by Seguin from the gallic acid, with which it had been confounded under the name of the astringent principle. He gave it the name of tannin, from its use in the tanning of leather; which it effects by its characteristic property, that of forming with gelatine a tough insoluble matter. It may be obtained from vegetables by macerating them in cold water; and precipitated from this solution, which contains likewise gallic acid and extractive matter, by hyperoxigenised muriate of tin. From this precipitate, immediately diffused in a large quantity of water, the oxide of tin may be separated by sulphureted hydrogen gas, leaving the tannin in solution.

Professor Proust has since recommended another method, the precipitation of a decoction of galls by powdered carbonate of potash, washing well the greenish-gray flakes that fall down with cold water, and drying them in a stove. The precipitate grows brown in the air, becomes brittle and shining like a resin, and yet remains soluble in hot water. The tannin in this state, he says, is very pure.

Sir H. Davy, after making several experiments on different methods of ascertaining the quantity of tannin in astringent infusions, prefers for this purpose the common process of precipitating the tannin by gelatin; but he remarks that the tannin of different vegetables requires different proportions of gelatin for its saturation; and that the quantity of precipitate obtained is influenced by the degree in which the solutions are concentrated.

M. Chenevix observed that coffee berries acquired by roasting the property of precipitating gelatin; and Mr. Hatchett has made a number of experiments, which show that an artificial tannin, or substance having its chief property, may be formed, by treating with nitric acid matters containing charcoal. It is remarkable that this tannin, when prepared from vegetable substances, as dry charcoal of wood, yields, on combustion, products analogous to those of animal matters. From his experiments it would seem that tannin is, in reality, carbonaceous matter combined with oxygen; and the difference in the proportion of oxygen may occasion the differences in the tannin procured from different substances, that from catechu appearing to contain most.

Bouillon Lagrange asserts that tannin by absorbing oxygen is converted into gallic acid. It is not an unfrequent practice, to administer medicines containing tannin in cases of debility, and at the same time to prescribe gelatinous food as nutritious. But this is evidently improper, as the tannin, from its chemical properties, must render the gelatin indigestible. For the chief use of tannin, see the following article.

According to Berzelius, tannin consists of hydrogen 4.186 + carbon 51.160 + oxygen 44.654. And the tannate of lead is composed of,

Tannin	100	26.923
Oxide of lead	52	14.

But there is much uncertainty concerning the definite neutrality of this compound.

TANNING. The several kinds of leather are prepared from the skins of animals macerated for a long time with lime and water, to promote the separation of the hair and wool, and of the fat and fleshy parts, in which recourse is also had to the assistance of mechanical pressure, scraping, and the like. The skin, when thus deprived of its more putrescible part, and brought considerably toward the state of mere fibre, is tanned by maceration with certain astringent substances, particularly the bark of the oak tree.

The hide consists almost wholly of gelatin, and all that is necessary is to divest it of the hair, epidermis, and any flesh or fat adhering to it. This is commonly done, after they have been soaked in water some time, and handled or trodden to cleanse them from filth, by immersing them in milk of lime. Some, instead of lime, use an accescent infusion of barley or rye-meal, or spent tan; and others recommend water acidulated with sulphuric acid. Similar acidulous waters are afterwards employed for raising or swelling the hide, when this is necessary. The skins, thus prepared, are finally to undergo what is properly called the tanning. This is usually done by throwing into a pit, or cistern made in the ground, a quantity of ground oak-bark that has already been used, and on the skins and fresh bark in alternate layers, covering the whole with half a foot of tan, and treading it well down. The tanning may be accelerated by adding a little water. As it is a long time before the hide is thoroughly tanned in this mode, at least many months, during which the bark is renewed three or four times; M. Seguin steeps the skins in a

strong infusion of tan, and assists its action by heat. Chaptal observes, however, that this requires an extensive apparatus for preparing the liquor and skins: the leather imbibes so much water that it remains spongy a long time, and wrinkles in drying; and it is extremely difficult so to arrange the hides in a copper as to keep them apart from each other, and free of the sides of the vessel.

The following account of M. Seguin's practice was transmitted to England in the year 1796:—To tan a skin is to take away its putrescent quality, preserving, however, a certain degree of pliability. This is effected by incorporating with the skin, particles of a substance which destroys their tendency to putrefaction.

The operations relating to tanning are therefore of two kinds:—the first is merely depriving the skin of those parts which would oppose its preservation, or which adhere to it but little, such as hair and flesh; the other consists in incorporating with it a substance, which shall prevent its putrefying. The operations of the first kind are technically termed, unhairing and fleshing; the operations of the second kind belong to tanning, properly so called. Fleshing is an operation merely mechanical; unhairing is a mechanical operation, if performed by shaving; or a chemical operation, if effected by dissolution or decomposition of the substance which connects the hair with the skin.

According to the ancient method, the dissolution of this substance was effected by means of lime; the decomposition either by the vinous fermentation of barley, by the acetous fermentation of oak-bark, or by the putrid fermentation produced by piling the hides one upon another. Unhairing by means of lime would often take twelve or fifteen months; this operation with barley, or the acetous part of tan, could not be performed in less than two months. The slowness of these operations, which the experiments of Seguin have shown may be finished in a few days, and in a more advantageous manner, by means of the same substances, proves that the nature of those operations was not understood by those who performed them. Those of tanning, properly so called, were as little known as the details we are about giving will prove, which we compare with the least improved routine now in practice. Whatever the method of unhairing was, the mode of tanning was always the same for skins unhairing with lime, or those prepared with barley or tan. This mode of operating would take eighteen months or two years, often three years, when it was wished to tan the hides thoroughly.

Among the substances for tanning, gall-nut, sumach, and the bark of oak, to which may be added catechu, appear the most proper, at least in the present state of our knowledge. In the middle departments of France, oak-bark is preferred, because it is the cheapest and most abundant substance. To use it, it is first ground to powder; then, according to the old mode, it is put into large holes dug in the ground, which are filled by alternate layers of ground bark and unhaird hides. As the principle which effects

the tanning cannot act in the interior of the skin, unless carried in by some liquid in which it is first dissolved, tanning is not produced by the immediate action of the powdered bark upon the skin, but only by the action of the dissolution of the tanning principle originally contained in the bark. The tan therefore has the tanning property only when wetted so much as not to absorb all the water thrown on it. But as tanners put in their vats only a small portion of water compared to what would be necessary to deprive the bark of all the tanning principle which it contains, the bark put into the vats preserves, when taken out, a portion of its tanning principle.

This waste is not the only disadvantage of the old modes of proceeding; they are, besides, liable never to produce in the skins a complete saturation with the tanning principle. For, as the property of attraction is common to all bodies, according to the different degree of saturation, the water containing in solution a certain quantity of the tanning principle will not part, to a fixed weight of skins, with as much as the same quantity of water will in which a greater quantity of the principle is dissolved.

As the water which, in the old manner of proceeding, is in the vats, can contain but a small portion of the tanning principle, owing to the nature of the operation, it can give but a small portion of it to the skin, and even this it parts with by slow degrees. Hence, the slowness in the tanning of skins, according to the old method, which required two whole years, and sometimes three, before a skin was well tanned to the centre. Hence, also, the imperfection of skins tanned by that method; an imperfection resulting from the non-saturation of the tanning principle, even when it had penetrated the centre.

The important desideratum was, therefore, to get together, within a small compass, the tanning principle, to increase its action, and produce in the hide a complete saturation in a much shorter time than that necessary for the incomplete tanning produced in vats. But, first of all, it was necessary to analyse the skin, analyse the leather, and analyse the oak-bark. The principles of these three substances were to be insulated, and their action upon one another determined, the influence of their combination upon that action known, and the circumstances most productive of its greatest action found out.

Seguin, by following this method, has determined:—1. That the skin deprived of flesh and hair is a substance which can easily, by a proper process, be entirely converted into an animal jelly (glue). 2. That a solution of this last mentioned substance, mixed with a solution of tan, forms immediately an imputescible and indissoluble compound. 3. That the solution of tan is composed of two very distinct substances; one of which precipitates the solution of glue, and which is the true tanning substance; the other which precipitates sulphate of iron, without precipitating the solution of glue, and which produces only the necessary disoxygenation of the skin, and of the substance which connects the hair to the skin. 4. That the operation of

tanning is not a simple combination of the skin with the principle which precipitates the glue, but a combination of that principle with the skin disoxygenised by the substance, which in the solution of tan is found to precipitate the sulphate of iron; so that every substance proper for tanning should possess the properties of precipitating the solution of glue, and of precipitating the sulphate of iron. 5. That the operation of tanning consists in swelling the skins by means of an acidulous principle; to disoxygenise, by means of the principle which in the solution of bark precipitates the solution of sulphate of iron, that substance which connects the hair to the skin, and thus produce an easy unhairing; to disoxygenise the skin by means of the same principle, and to bring it by this disoxygenation to the middle state between glue and skin; and then to combine with it, after this disoxygenation and while it is in this middle state, that particular substance in oak-bark, as well as in many other vegetables, which is found to precipitate the solution of glue, and which is not, as has been hitherto conceived, an astringent substance.

Agreeably to these discoveries, there only remains, in order to tan speedily and completely, to condense the tanning principle so as to accelerate its action. Seguin, to effect this, follows a very simple process. He pours water upon the powdered tan, contained in an apparatus nearly similar to that made use of in saltpetre works. This water, by going through the tan, takes from it a portion of its tanning principle, and by successive filtrations dissolves every time an additional quantity of it, till at last the bark rather tends to deprive it of some than to give up more. Seguin succeeds in bringing these solutions to such a degree of strength, that, he says, he can, by taking proper measures, tan calf-skin in twenty-four hours, and the strongest ox-hides in seven or eight days. These solutions, containing a great quantity of the tanning principle, impart to the skin as much of it as it can absorb, so that it can then easily attain a complete saturation of the principle, and produce leather of a quality much superior to that of most countries famous for their leather.

‘On the above I have only to remark,’ says Dr. Ure, ‘that every new art or considerable improvement must unavoidably be attended with many difficulties in the establishment of a manufactory in the large way. From private enquiry I find that this also has its difficulties, which have hitherto prevented its being carried into full effect in this country. Of what nature these may be I am not decidedly informed, and mention them in this place only to prevent manufacturers from engaging in an undertaking of this kind, without cautious enquiry.’

M. Desmond has recommended to saturate water with tannin by affusion on successive portions of oak-bark, or whatever may be used; and, when the bark will give out no more tannin, to extract what gallic acid still remains in it, by pouring on fresh water. To the latter, or acidulous liquor, he adds $\frac{1}{1000}$ th part by measure of sulphuric acid; and in this steeps the hide, till the hair will come off easily by scraping. When raising is necessary, he steeps the hide ten or

twelve hours in water acidulated with $\frac{1}{500}$ th part by measure of sulphuric acid; after which they are to be washed repeatedly, and scraped with the round knife. Lastly, the hides are to be steeped some hours in a weak solution of tannin, then a few days in a stronger, and this must be renewed as the tannin is exhausted, till the leather is fully tanned.

For the softer skins, as calves, goats, &c., he does not use the acid mixture, but milk of lime. Of substances used for tanning Sir H. Davy observes, that one pound of catechu is nearly equal to two pound and a quarter of galls, three of sumach, seven and a half of the bark of the Leicester willow, eight and a half of oak-bark, eleven of the bark of the Spanish chestnut, eighteen of elm-bark, and twenty-one of common willow bark, with respect to the tannin contained in them. He observes, too, that leather slowly tanned in weak infusions of barks appears to be better in quality, being both softer and stronger than when tanned by strong infusions; and he ascribes this to the extractive matter they imbibe. This principle, therefore, affects the quality of the material employed in tanning; and galls which contain a great deal of tannin make a hard leather, and liable to crack, from their deficiency of extractive matter.—Vide Ann. de Chim. et de Phys.—Philos. Trans.—Philos. Mag.—Chaptal’s Chem.

A more practical view of this useful art may be thus given:—When the hides which are to be tanned are raw (in which state they are called green hides), they are put to steep in water, in order to clear them of the blood and filth they may have collected in the slaughter-house. They are left to soak in the water for some time, and, if the hides are dry, they are steeped a longer time, sometimes for fourteen days; less in hot weather, or more in cold. They are drawn out once or twice to see if they are well softened. The neighbourhood and the command of water are necessary to these operations. Without these the hides cannot be prepared.

After the hides have been well softened, they next proceed to cleanse or free them from the hair. With this intention several different methods are employed; that which is the oldest, and still most generally followed, consists in the application of lime. In all tanneries, pits are formed under-ground, having their sides lined with stone or brick, in which lime-stone is slaked so as to form milk of lime. These pits are divided into three kinds, according to the greater or less strength of the lime. The hides intended to be scoured are first put into the weakest of these pits, wherein they are allowed to remain until the hair readily yields to the touch. If this liquor be not sufficiently active, they are removed to the next in gradation. The time they are soaked is longer or shorter in proportion to the strength of the lime, the temperature of the air, and the nature of the hides. It has been proposed to substitute lime-water in place of the milk of lime. But, though the lime-water acts at first with sufficient strength, its action is not sufficiently permanent, and, in order to succeed in clearing the hides by this means, it is necessary to renew it occasionally; and in this way the

hides may be prepared in a few days. In some tanneries, after they have been kept in the pits for a short time, they pile them up in a heap on the ground, in which state they are suffered to remain during eight days; after which they return them into the same pits whence they were taken, and this process is repeated till the hair can be easily scraped off.

In many countries they mix a large quantity of ashes with the lime; but the only effect this mixture appears to produce, is that of rendering the leather less consistent than when lime is solely employed. Many attribute the bad qualities of leather to the too great use of lime, which has a tendency to burn and render it brittle. Hence, in several well-conducted tanneries, in manufacturing leather for some particular uses, the employment of lime is carefully avoided. Hides may, indeed, be cleansed by subjecting them to an incipient fermentation, which may be produced in a variety of ways. But, in whatever manner the first part of the operation has been conducted, as soon as it is perceived that the hair is in a fit state to be removed, it is scraped off, on a wooden horse, by means of a crooked knife, which is not so sharp in any part of its edge as to injure the hide, or by a whet-stone. This operation is not only intended to remove the hair, but likewise the scurf and filth which collect on the skin at the root of the hair.

After removing the hair and filth, the next object is to free the hides from the adhesion of any part of the muscle, or fat, and to render them soft and pliant. Those which are intended for particular kinds of work, such as calves' skin for the upper leather of shoes, and neats' leather for shoulder-belts, do not require to be raised or swelled. As soon, therefore, as they are cleansed and freed from the flesh, &c.; they are laid in a pit. The hides intended for the soles of shoes, and other strong leathers, are afterwards raised by means of processes which vary in different countries. *When lime is employed, the operation is commenced by putting the cleansed skins into the weakest of the lime-pits, and afterwards passing them successively through the two others. They are kept about a week in each of the two weakest pits, and another in the strongest. During this operation care is taken to withdraw them, and pile them up in a heap, every two or three days, putting them again into the pit after it has been well stirred. Lime hardens the skin, and in those tanneries where it is used, the hides are put into a ley of pigeon's dung in order to soften them, and this process is termed graining. They are daily withdrawn from the ley, and laid up in a heap for half an hour. This operation is usually continued for ten or fifteen days. Sometimes also acid compositions are employed for raising the hides; and this operation is greatly accelerated by using the acids warm, as well as by the method practised in this country, of removing them from a weaker liquor into a stronger, until they be properly raised or swelled.

The skin, being thus prepared, is next subjected to the operation of tanning; and to this purpose vegetable astringents are employed. **Those vegetables answer best which contain the**

greatest portion of the astringent principle, now known under the name of tannin. Sir H. Davy has demonstrated that caoutchouc, or Japan earth, contains more of this principle than any other vegetable with which we are acquainted; but oak bark is the substance most commonly employed in our climates; for it is not only very abundant in Europe, but likewise contains much tannin. Every species of oak, however, does not supply us with bark of the same quality; the white oak is inferior to the green oak which grows in the south, while this in its turn yields in the value of its bark to that procured from the roots of the kermes-bearing oak, which is employed in southern climates for tanning strong leathers. But, whatever kind of bark be employed, it is ground down to powder. The tan-pits are sometimes of a round, and at others of a square form, dug out to a considerable depth in the earth, and lined with wood or mason-work; their size being in proportion to the extent of the works. The method of tanning is different in different countries. According to calculation, from five to six pounds of tan is required to each pound of strong leather; and 1 cwt. of hides yields from fifty-two to sixty-six pounds of leather.

We will now detail another method chiefly taken from Sir H. Davy's memoir on the subject. After the skin has been cleaned, it is submitted to other operations before it is immersed in the tan liquor. According to Sir Humphry's account of the practices of the art, the large and thick hides which have undergone incipient putrefaction, are introduced for a short time into a strong infusion of oak bark, and after this they are acted on by water impregnated with a little sulphuric or acetic acid; in consequence of which they become harder and denser than before, and fitted after being tanned, for the purpose of forming the stouter kinds of sole leather. The lighter and thinner skins are treated in a different manner: they are macerated for some days in a ley formed from the infusion of pigeons' dung in water, which contains a little carbonate of ammonia; the skin is thus deprived of its elasticity, and becomes more soft. The tanning liquor is prepared by infusing bruised oak bark in water; and skins are tanned by being successively immersed in such infusions, saturated in different degrees with the astringent principles of the bark. The first leys in which they are immersed are weak, but towards the completion of the process they are used as strong as possible; and, in preparing stout sole leather, the skins are kept in an ooze, approaching to saturation, by means of layers of oak bark.

The infusion of oak bark, especially that obtained by the first maceration, contains principally tannin and extractive matter; the gallic acid, if present, as has been supposed, being at least in an inconsiderable proportion. In the course of the maceration of the skins in these liquors, the tannin combines gradually with the gelatin, which, in an organised form, principally constitutes the skin, and forms with it a compound insoluble in water; dense and impermeable to that fluid, while it possesses at the same time a certain degree of elasticity. The extractive matter also enters into the combination; for

when skin in a large quantity has exerted its full action on a small quantity of infusion, it at length abstracts the whole dissolved matter, and renders it colorless. From this extractive matter color is derived, and the skin may perhaps be rendered more dense.

It has been supposed that the gallic acid, frequently contained in vegetable astringents, facilitates the action of their tanning, in converting skin into leather. According to the theory of the operation, as given by Seguin, skin is gelatin in a hardened state from slight oxidisement; the gallic acid in some measure de-oxidizes it, and hence reduces it to that state in which it combines more easily with gelatin. There is little proof given, however, of this theory; and it appears sufficiently established that the operation can be performed without the presence of this acid; and indeed in the tan liquor prepared by one maceration from oak bark it is scarcely discoverable, and, if it do exist in it, it is in intimate combination with the extractive matter.

The operation of tanning, as now described, requires a number of months, from the skins being successively and slowly introduced into infusions of different degrees of strength. We have seen that Seguin, after his discovery of tannin, proposed to abridge the process by introducing the skins more speedily into strong infusions of the tanning substance; and in this way, according to the excellent report given on the art of tanning by Pelletiere and Lelivre, in which his method is fully described, the whole could be finished in about twenty days, and leather obtained equal in quality to that prepared by the old method. There is reason, however, to doubt of the superiority of this method. Mr. Nicholson, in some observations on this subject, when a patent was taken out for Seguin's method in this country, stated that, from information acquired from the manufacturers, he found that they had previously been sufficiently acquainted with the powers of the strong tanning infusions; and that it had been even proposed to employ them so as to abridge the process. But the leather thus prepared was by no means equal to that prepared in the old method. The advantage of the slow and gradual process appears to be, that the whole substance of the skin is penetrated and equally changed; while in the more rapid method the external parts must be more acted on; and the texture probably will be more unequal. It appears also, from Sir H. Davy's experiments, to combine with a larger quantity of the extractive matter contained in the astringent infusion; and hence too the advantage of the immersions in the weak liquors, as these contain more of this than the strong infusions. It must be confessed, however, that for any thing theory can discover, the common process appears to be unnecessarily protracted, and some advantage might probably be derived from adopting some of the manipulations of Seguin. The skin in drying increases in weight from the fixation of the vegetable matter: the quantity of this seldom exceeds one-third of its weight.

Of tawing, leather-dressing and dyeing, and other processes.—The dressing and preparing of the skins of lambs, sheep, goats, and other thin

hides, though in many particulars closely resembling the method used with the thick cow and ox hides, forms a totally distinct branch of business, and is one in which a good deal of practical skill and nicety of manipulation are required to succeed perfectly. The processes are various according to the article required, and this branch of the manufacture supplies the immense demand of white and dyed leather for gloves, the morocco leather of different colors and qualities for coach-linings, book-binding, pocket-books, and thin leather for an infinite number of smaller purposes. Of these the white leather alone is not tanned, but finished by the process of tawing; the colored leather receives always a tanning independently of the other dyeing materials. The previous preparation of each, or that in which the skin is thoroughly cleansed and reduced to the state of simple membrane in which it is called pelt, is essentially the same whether for tawing or dyeing. It is thus performed at Bermondsey, near London, a place long celebrated for all branches of the leather business.

By far the greater number of the skins are imported: if lambs they are thus prepared:—The skins are soaked for a time in water to cleanse them from any loose dirt and blood, and put upon the beam commonly used for the purpose, which is a half cylinder of wood covered with leather, and scraped on the flesh side with the semicircular blunt knife with two handles used in this operation. They are then covered with a coat of lime of the consistence of paint on the flesh side, and hung up in considerable numbers in a small close room heated by flues, where they remain to putrefy for a given time. During this process a thick slime works up to the surface of the skin, by which the regularity of the process is ascertained, and the wool is loosed so that it readily comes off with a slight pull. Each skin is then returned to the beam, the wool taken off, and all the lime worked off with the knife, and the rough edges pared away. The skin is then put into a pit filled with lime-water, and kept there from two to six weeks, according to the nature of the skin, which has the effect of checking the further putrefaction, and produces a very remarkable hardening and thickening of its substance, and probably also it detaches a further portion of the slime. The skin is again well worked, and much of its substance pared down, and all inequalities smoothed with the knife. Pains and judgment are required in these operations, on the one hand not to endanger the substance of the skin by the putrefaction, and on the other hand to work out every particle of the lime, of which the least if retained will prevent the skin from dressing well in the subsequent processes, and from taking the dye uniformly and well. The skin is then again softened and freed from the lime. All the thickening produced by the lime is thus removed, and the skin is now highly purified, and is a thin extensible white membrane called in this state a pelt, and is fit for any subsequent operation of tawing or dyeing, or oil-dressing, or shammoing.

The method of bringing kid and goats' skins to the state of pelt is nearly the same as for lambs, except that the lining is used before the

hair is taken off, the hair being of but little importance and only sold to the plasterers; but the lambs' wool, which is more valuable, would be greatly injured by the lime. Kids' skins will take a longer time in tanning than lambs'.

If the pelts are to be tawed they are put into a solution of alum and salt in warm water, in the proportion of three pounds of alum and four pounds of salt to every 120 middle sized skins, and worked therein till they have absorbed a sufficient quantity. This again gives the skin a remarkable degree of thickness and toughness.

The skins are now taken out and washed in water, and then again put into a vat of bran and water, and allowed to ferment till much of the alum and salt is got out, and the unusual thickening produced by it is for the most part reduced. They are then taken to a room with a stove in the middle, and stretched on hooks, and kept there till fully dry. The skins are now converted into a tough, flexible, and quite white leather; but to give them a glossy finish, and to take off the harshness of the feel still remaining, they are again soaked in water and put into a large pail containing the yolks of eggs beat up with water. Here the skins are trodden for a long time, by which they so imbibe the substance of the egg that the liquor above them is rendered almost perfectly limpid; after which they are hung up in a loft to dry, and finished by glossing with a warm iron.

The essential difference, therefore, between tanning and tawing is that in the former case the pelt is combined with tan and other vegetable matter, and in the latter with something that it imbibes from the alum and salt (possibly alumine), and which is never again extracted by the subsequent washing and branning.

The Morocco leather, as it is called, prepared from sheep skins chiefly, and used so largely for coach-linings, pocket-books, and the best kind of book-binding, is thus made:—The skin, cleansed and worked in the way already described, is taken from the lime-water, and the thickening brought down, not by bran-liquor as in tawing, but by a bath of dogs' or pigeons' dung diffused in water, where it remains till suppled, and till the lime is quite got out and it becomes a perfectly white clean pelt. If intended to be dyed red, it is then sewed up very tight in the form of a sack with the grain side outwards, and is immersed in a cochineal bath of a warmth just equal to what the hand can support, and is worked about for a sufficient time till it is uniformly dyed. The sack is then put into a large vat containing sumach infused in warm water, and kept for some hours till it is sufficiently tanned. The skins intended to be black, or any color but red, are merely sumached without any previous dyeing. After some further preparation, the color of the red skins being finished with a weak bath of saffron, the skins when dry are grained and polished in the following way:—They are stretched very tight upon a smooth inclined board, and rubbed over with a little oil. Those intended for black leather are previously rubbed over with an iron liquor, which, uniting with the gallic acid of the sumach, instantly strikes a deep and uniform black.

They are then rubbed by hand with a ball of glass with much manual labor, which polishes them and makes them very firm and compact. Lastly, the graining or ribbed surface by which this kind of leather is distinguished, is given by rubbing the leather very strongly with a ball of box-wood, round the centre of which a number of small equidistant parallel grooves are cut, forming an equal number of narrow ridges, the friction of which gives the leather the desired inequality of surface.

The process for the real Morocco leather, as prepared from goat-skins at Fez and Tetuan, is thus described by M. Broussopet:—The skins are first cleansed, the hair taken off, limed, and reduced with bran nearly in the way already described for the English morocco leather. After coming from the bran they are thrown into a second bath made of white figs mixed with water, which is thereby rendered slimy and fermentable. In this bath the skins remain four or five days, when they are thoroughly salted with sal-gem, or rock salt alone, after which they are fit to receive the dye, which for the red is cochineal and alum, and for the yellow pomegranate bark and alum. The skins are then tanned, dressed, suppled with a little oil, and dried.

Much excellent leather, and of various colors, is manufactured in different parts of Russia; of which the processes are given in Mr. Tooke's *View of the Russian Empire*, vol. iii. The saffian, or manouquin, which is prepared largely at Astracan, is manufactured only from the skins of goats and bucks; the usual colors of these are red and yellow. The shagreen, which is also manufactured at Astracan, consists of hides of horses and asses; but of these only a small part is used, cut from the crupper-line along the back about thirty-four inches upon the crupper, and twenty-eight along the back. The chief dyes of shagreen are green, blue, and black.

Various processes have been invented to render leather for shoes and boots water-tight, which is effected by an additional dressing with an oily or resinous matter; the following recipe is said to be effectual:—One pound of linseed-oil; half a pound of mutton suet; six ounces of bees-wax, and four of resin, are to be melted, thoroughly incorporated, and applied, while warm, to the upper-leather and the soles.

TANSILLO (Lewis), a celebrated Italian poet, born at Nola, about 1510. His poem, entitled *Il Vendimiatore*, i. e. the *Vintager*, being very indecent, all his poems were proscribed. To make some reparation for this error, he wrote *La Lagrime de St. Pietro*, i. e. the *Tears of St Peter*; which being presented to Pope Paul IV. he took off the interdict from all his poems, except the *Vintager*. He died about 1569.

TANTALIDES, in fabulous history, the descendants of Tantalus, as Atreas, Agamemnon, Menelaus, &c.

TANTALIZE, *v. a.* } From Tantalus,
TANTALISM, *n. s.* } whose punishment
TANTLING. } was to starve among
fruits and water which he could not touch. To torment by the show of unattainable pleasure: tantalism is a punishment of this kind: tantling, one who is seized with unattainable hopes.

Hard life,
To be still hot Summer's *tantlings*, and
The shrinking slaves of Winter. *Shakspeare.*

Thy vain desires, at strife
Within themselves, have *tantalized* thy life. *Dryden.*

The maid once sped was not suffered to *tantalize*
the male part of the commonwealth. *Addison.*

A lively representation of a person lying under the
torments of such a *tantalism*, or platonick hell.
Id. Spectator.

TANTAMOUNT, *n. s.* French, *tantamount*.
Equivalent.

If one-third of our coin were gone, and men had
equally one-third less money than they have, it must
be *tantamount*; what I scape of one-third less, another
must make up. *Locke.*

TANTALUS, in fabulous history, king of
Phrygia and Paphlagonia, was the son of Jupiter
and the nymph Plota. He one day entertained
the gods at his table; when, to prove their divi-
nity, he served up his son Pelops cut in pieces.
All the deities except Ceres perceived his
cruelty and impiety, and would not touch his
provisions. That goddess inadvertently eat a
part of his left shoulder. Pelops, however, was
restored to life; and an ivory shoulder given him
in the room of that which had been eaten; but
Tantalus was thrown into Tartarus, where he
was punished with perpetual hunger and thirst.
He was chained in a lake: the water of which
reached up to his chin, but retired when he at-
tempted to drink. The branch of a tree loaded
with fruit hung down even to his lips, but on his
attempting to pluck the fruit, the branch sprung
upwards.

TANTALUS, a son of Thyestes, the first hus-
band of Clytemnestra. Paus. 2

TANTALUS, in ornithology, a genus of birds
belonging to the order of gallæ. The bill is
long, subulated, and somewhat crooked; the face
naked; the tongue short; and the feet have four
toes palmed on the under part. There are, accord-
ing to Dr. Latham, twenty-three species; of
which the most remarkable is the *T. ibis*. the ibis,
the bird so much valued by the ancient Egyptians
for its utility in freeing the country from serpents,
but now no longer found in Egypt. Mr. Bruce
found a bird in Abyssinia, which, after comparing
it with the description of the ancient writers,
and the embalmed ibis of Egypt, he concludes
is the same with the Egyptian ibis. It is mi-
nutely described by Mr. Bruce. It has a beak
shaped like that of a curlew, two-thirds straight,
and the remaining third crooked; the upper part
of a green horny substance, and the lower part
black. It measures four inches and a half
from the occiput to the place where it joins the beak.
The leg, from the lower joint of the thigh to the
foot, is six inches; the bone round and very
strong; and, from the lower joint of the thigh to
where it joins the body, is five inches and a half.
The height of the body from the sole to the middle
of the back is nineteen inches; the aperture
of the eye one inch; the feet and legs black; three
toes before armed with sharp and straight claws;
and a toe behind. The head is brown, and the
plumage of the same color down to the back, or
the place where the neck and back are joined.
The throat is white, as well as the back, breast,

and thighs; the largest feathers of the wing are
of a deep black for thirteen inches from the tail;
and six inches up the back from the extremity
of the tail is black likewise.

TAP, *v. a. & n. s.* } Fr. *tapper*; Belg. *tap-*
TAP'STER, *n. s.* } *pen.* To touch or strike
lightly; to pierce or broach a vessel. It is used
likewise of the liquor: a pipe out of which the
liquor spouts: a tapster is one whose business it
is to draw beer.

The oath of a lover is no stronger than the word of
a *tapster*; they are both the confirmers of false reckon-
ings. *Shakspeare.*

This is the right fencing grace, *tap* for *tap*, and so
part fair. *Id. Henry IV.*

That blood already, like the pelican,
Hast thou *tapt* out, and drunkenly caroused.

Shakspeare.
The world is come now to that pass that the vint-
ner and *tapster* may broach what religion they please;
and the apothecary may mingle her as he pleases.
Howel.

Some put under the trees raised of seed, about four
inches below the place where they sow their seeds, a
small piece of tile to stop the running down of the
taproot, which occasions it to branch when it comes
to the tile. *Mortimer's Husbandry.*

He has been *tapping* his liquors, while I have been
spilling my blood. *Addison.*

Each shakes her fan with a smile, then gives her
right hand woman a *tap* upon the shoulder.

Id. Spectator.

As at hot cockles once I laid me down,
And felt the weighty hand of many a clown,
Buxoma gave a gentle *tap*. *Gay's Pastorals*

Wait with patience till the tumour becomes
troublesome, and then *tap* it with a lancet.

Sharp's Surgery.
A gentleman was inclined to the knight of Gas-
cogne's distemper, upon hearing the noise of a *tap*
running. *Derham.*

Though the painting grows decayed,
The house will never lose its trade;
Nay, though the treacherous *tapster* Thomas
Hangs a new angel two doors from us. *Swift.*

So Huron-leeches, when their patient lies
In feverish restlessness with unclosed eyes,
Apply with gentle strokes their ozier rod,
And *tap* by *tap* invite the sleepy god. *Hart.*

TAPANOOLY, a British settlement of Su-
matra, on the island of Puchong Keechil, at the
bottom of the Bay of Tapanooly, on the north-
west shore, distant about two miles and a half
or three miles. The Bay of Tapanooly, with the
island of Mansalar, forms one of the finest ports
in the world.

TAPAYOS, or TAPAJOS, a magnificent river
of Brasil, in the capitania of Matto Grosso, which
derives its copious sources from numerous
branches rising in the interior mountains. It is
one of those great rivers which come from the
south and feed the vast stream of the Amazons.
Its course is north for more than 600 miles be-
tween the Chingu and the Madera, and it falls
into the Amazons in long. 55° W. lat. 2° 24'
50" S.

TAPE, *n. s.* Sax. *teppan*; Isl. and Swed.
tepp. A narrow fillet or band of linen.

Will you buy any *tape*, or lace for your cape,
My dainty duck, my dear-a? *Shakspeare*

This pounch that's tied with a *tape*
I'll wager that the prize shall be my due *Gay*.

On once a flock-bed, but repaired with straw,
With *tape*-tied curtains never meant to draw. *Pope*.

TAPER, *n. s.*, *adj.*, & *v. n.* Saxon; *taperen*;
Goth. *tap*; Swed. *top*. A wax candle; a light:
the adjective means pyramidal or conical, from
the form of a taper: the verb neuter, to grow
gradually smaller or towards a point.

Get me a *taper* in my study, Lucius:
When it is lighted, come and call me. *Shakspeare*.

If any snatch the pure *taper* from my hand, and
hold it to the devil, he will only burn his own fingers,
but shall not rob me of the reward of my good in-
tention. *Taylor*.

There the fair light,
Like Hero's *taper* in the window placed,
Such fate from the malignant air did find,
As that exposed to the boisterous wind. *Waller*.

To see this fleet,
Heaven, as if there wanted lights above,
For *tapers* made two glaring comets rise. *Dryden*.

Her *taper* fingers, and her panting breast,
He praises. *Id*.

The back is made *tapering* in form of a pillar, the
lower vertebres being the broadest and largest; the
superior lesser and lesser, for the greater stability of
the trunk. *Ray*.

From the beaver the otter differs in his teeth,
which are canine; and in his tail, which is feline, or
a long *taper*. *Grew*.

Such be the dog,
With *tapering* tail, that nimbly cuts the wind. *Tickell*.

TAPER, or **TAPERING**, is understood of a
piece of timber, or the like, when thick at one
end and gradually diminishing to the other; as
is the case in pyramids, cones, &c.

TAPER also denotes a kind of tall wax candle,
placed in a candlestick, and burnt at funeral pro-
cessions and in other church solemnities. Tapers
are made of different sizes; in some places, as
Italy, &c, they are cylindrical; but in most
other countries, as England, France, &c., they
are conical or taper; whence the name; unless
we derive it in the adjective sense, from the sub-
stantive taper, Saxon, *tapen*, or *tapon*, cereus,
wax-candle. Both kinds are pierced at bottom
for a pin in the candlestick to enter. There are
two ways of making tapers, the first with the
ladle, the second by hand. See **CANDLE**.

TAPER, **PASCHAL**, among the Romanists, is a
large taper, whereon the deacon applies five bits
of frankincense, in holes made for the purpose,
in form of a cross; and which he lights with new
fire in the ceremony of Easter Saturday. The
pontifical makes pope Zosimus the author of
this usage; but Baronius will have it more
ancient, and quotes a hymn of Prudentius to
prove it. F. Papebroch gives the original of the
paschal taper in his *Conatus Chronico-Historicus*,
&c. Though the council of Nice regulated
the day whereon Easter was to be celebrated, it
enjoined the patriarch of Alexandria to make a
yearly canon thereof, and to send it to the pope.
As all the other moveable feasts were regulated
by that of Easter, a catalogue of them was made
every year; and this was written on a consec-
rated taper, cereus. This taper, according to
the abbot Chastelain, was not made to be burnt;
it had no wick, and was only a column of wax,

made to write the list of moveable feasts on for
a year. For the ancients, when any thing was
to be written to last for ever, engraved it on
marble or steel; when it was to last a long while
they wrote it on Egyptian paper; and when it
was only to last a short time they wrote it on
wax. They came at last to write the moveable
feasts on paper, but they still fastened it to the
paschal taper.

TAPER-BORED (taper and bored) is applied
to a piece of ordnance when it is wider at the
mouth than towards the breech.

TAP'ESTRY, *n. s.* Fr. *tapesterie*, *tapisserie*,
tapis; Lat. *tapetum*; Gr. *ταπις*. Cloth woven
in regular figures. See below.

In the desk
That's covered o'er with Turkish *tapestry*,
There is a purse of ducats. *Shakspeare*.

The casements are with golden tissue spread,
And horses' hoofs, for earth, on silken *tap'stry* tread. *Dryden*.

One room is hung with *tapestry*, in which are
wrought the figures of the great persons of the fam-
ily. *Addison*.

TAP'ESTRY. The art of weaving *tapestry* is
borrowed from the Saracens; accordingly the
workmen employed in this manufacture in France
were formerly called Sarazins or Sarazinois.
Guicciardini ascribes the invention of *tapestry*
hangings to the inhabitants of the Netherlands;
but he has not mentioned at what time the dis-
covery was made. This art was brought into
England by William Sheldon near the end of
Henry VIII.'s reign. In 1619 a manufacture was
established at Mortlake, in Surry, by Sir Francis
Crane, who received £2000 from king James to
encourage it. The first manufacture of *tapestry*
at Paris was set up under Henry IV. in 1606 or
1607 by several artists whom that monarch in-
vited from Flanders. Under Louis XIV. the
manufacture of the Gobelins was instituted,
which introduced very beautiful cloths, remark-
able for strength, for elegance of design, and a
happy choice of colors. The finest paintings
are copied, and eminent painters have been em-
ployed in making designs for the work.

Tapestry is distinguished by the workmen into
two kinds, viz. high and low warp; though the
difference is rather in the manner of working
than in the work itself; which is in effect the
same in both; only the looms, and consequently
the warps, are differently situated; those of the
low warp being placed flat and parallel to the
horizon, and those of the high warp erected per-
pendicularly. The English anciently excelled
all the world in the *tapestry* of the high warp;
and they still retain their former reputation,
though with some little change: their low warps
are still admired; but the high ones are quite
laid aside by the French. The French, before
the Revolution, had three considerable *tapestry*
manufactures besides that of the Gobelins; the
first at Abusson in Ouvergne, the second at Fel-
lettin in the Upper Marche, and the third at
Beauvais. They were all equally established for
the high and the low warp; but they had all laid
aside the high warp excepting the Gobelins. There
were admirable low warps likewise in Flanders
generally exceeding those of France; the chief
and almost only Flemish manufactures were a

Brussels, Antwerp, Oudenard, Lisle, Tournay, Bruges, and Valenciennes. The usual widths of tapestry are from two to three ells Paris measure.

The loom on which it is wrought is placed perpendicularly: it consists of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are set upright, and the beams across them, one at the top and the other at the bottom, or about a foot from the ground. They have each their trunnions, by which they are suspended on the planks, and are turned with bars. In each roller is a groove from one end to the other, capable of containing a long round piece of wood, fastened with hooks to tie the ends of the warp to. The warp, which is a kind of worsted, or twisted woollen thread, is wound on the upper roller; and the work, as fast as wove, is wound on the lower. Within the planks, which are seven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end serving to sustain the coat stave; these pieces of iron have also holes pierced by putting a pin in which the stave is drawn nearer or set farther off; and thus the coats or threads are stretched or loosened at pleasure. The coatstave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats or threads, which make the threads of the warp cross each other. It has much the same effect as the spring-stave and treddles have in the common looms. The coats are little threads fastened to each thread of the warp with a kind of sliding knot, which forms a sort of mash or ring. They serve to keep the warp open for the passage of broaches wound with silks, woollens, or other matters used in the piece of tapestry. In the last place there are a number of little sticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baskets, to make the threads of the warp cross each other by passing them across; and, that the threads thus crossed may retain their proper situation, a packthread is run among them above the stick. The loom being thus formed, and mounted with its warp, the first thing the workman does is to draw on the threads of this warp the principal lines and strokes of the design to be represented on the piece of tapestry; by applying cartoons made from the painting he intends to copy to the side that is to be the wrong side of the piece, and then, with a black lead pencil, following and tracing out the contours thereof on the thread of the right side; so that the strokes appear equally both before and behind. The original design of the work is hung up behind the workmen, and wound on a long staff, from which a piece is unrolled from time to time as the work proceeds. Besides the loom, &c., here described, there are three other principal instruments required for working the silk or the wool of the woof within the threads of the warp; these are a broach, a reed, and an iron needle. The broach is made of hard wood, seven or eight inches long, and two-thirds of an inch thick, ending in a point with a little handle. This serves as a shuttle, the silks, woollens, gold, or silver, to be used in

the work being wound on it. The reed or comb is also of wood, eight or nine inches long, and an inch thick on the back, whence it grows less and less to the extremity of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only bigger and longer. Its use is to press close the wool and silks when there is any line or color that does not fit well. All things being prepared for the work, and the workman ready to begin, he places himself on the wrong side of the piece, with his back towards the design: so that he works as it were blindfold, seeing nothing of what he does, and being obliged to quit his post, and go to the other side of the loom whenever he would view and examine the piece, to correct it with his pressing-needle. To put silk, &c., in the warp, he first turns and looks at the design; then, taking a broach full of the proper color, he places it among the threads of the warp, which he brings across each other with his fingers, by means of the coats or threads fastened to the staff; this he repeats every time he has to change his color. Having placed the silk or wool, he beats it with his reed or comb; and, when he has thus wrought in several rows over each other, he goes to see the effects they have, in order to reform the contours with his needle, if there be occasion. As the work advances it is rolled upon the lower beam, and they unroll as much warp from the upper beam as suffices them to continue the piece: the like they do of the design behind them. When the pieces are wide several workmen may be employed at once. The high warp tapestry goes on much more slowly than the low warp, and takes up almost twice the time and trouble. All the difference that the eye can perceive between the two kinds consists in this, that in the low warp there is a red fillet, about one-twelfth of an inch broad, running on each side from top to bottom, which is wanting in the high warp.

The loom or frame whereon the *low warp* is wrought is much like that of the weavers: the principal parts are two strong pieces of wood forming the sides of the loom, and bearing a beam or roller at each end; they are sustained at bottom with other strong pieces of wood in manner of trestles; and to keep them firm they are fastened to the floor with a kind of buttresses, which prevent any shaking, though there are sometimes four or five workmen leaning on the fore-beam at once. The rollers have each their trunnions, by which they are sustained: they are turned by large iron pins, three feet long. Along each beam runs a groove, wherein is placed the wick, a piece of wood about two inches diameter, and almost the length of the roller: this piece fills the groove entirely, and is fastened therein, from space to space, by wooden pins. To the two wicks are fastened the two extremities of the warp, which is wound on the farther roller, and the work, as it advances, on the nearer. Across the two sides, almost in the middle of the loom, passes a wooden bar, which sustains little pieces of wood, not unlike the beam of a balance: to these pieces are fastened strings, which bear certain spring-staves, where-

with the workman, by two treddles under the loom whereon he sets his feet, gives a motion to the coats, and makes the threads of the wasp rise and fall alternately. Each loom has more or fewer of these spring-staves, and each staff more or fewer coats, as the tapestry consists of more or fewer threads. The design or painting the tapestry worker is to follow is placed under the warp; where it is sustained from space to space with strings, by which the design is brought nearer the warp. The loom being mounted, two instruments are used in working it, viz. the reed and the flute. The flute does the office of the weaver's shuttle; it is made of hard polished wood, three or four lines thick at the ends, and somewhat more in the middle, and three or four inches long. On it are wound the silks or other matters to be used as the woof of the tapestry. The comb or reed is of wood or ivory; it has usually teeth on both sides; it is about an inch thick in the middle, but diminishes each way to the extremity of the teeth; it serves to beat the threads of the woof close to each other, as fast as the workman has passed and placed them with his flute among the threads of the warp. The workman is seated on a bench before the loom, with his breast against the beam, only a cushion or pillow between them; and, in this posture, separating with his fingers the threads of the warp that he may see the design underneath, and taking a flute mounted with a proper color, he passes it among the threads, after having raised or lowered them by the treddles moving the spring-staves and coats. Lastly, To press and close the threads of the silk or yarn, &c., thus placed, he strikes each course (i. e. what the flute leaves in its passing and coming back again) with the reed. See WEAVING.

TAPET, *n. s.* Latin, *tapetia*. Worked or figured stuff.

To their work they sit, and each doth chuse
What story she will for her *tapet* take. *Spenser*.

TAPHIÆ, in ancient geography, islands in the Ionian Sea, between Achaia and Leucadia, called also Teleboides, from Taphius and Telebous. The Taphians made war against Electryon, king of Mycenæ, and killed all his sons. Upon this he promised his daughter Alcmena, with his kingdom, to any man who should avenge him of the Taphians. This was accomplished by Amphitryon.—*Hom. Od. i. 181, &c.* See **ALC MENA**.

TAPHIANS, the natives of the Taphiæ. They were expert sailors, but addicted to piracy.—*Plin. iv. c. 12.*

TAPHIASSUS, or **TAPHIUS**, a mountain of Locris, on the confines of Ætolia.—*Lempr.*

TAPHIUS, and **TELEBOUS**, in fabulous history, the sons of Neptune, by Hippothoe, the daughter of Nestor: they reigned in the Taphiæ, and gave their names to them.—*Strabo*, 10.

TAPHIUSA, a town near Leucas, famous for a particular stone, called taphiusius.—*See Plin. 36. c. 21.*

TAPHIRÆ, an ancient town on the isthmus of Taurica Chersonesus; now called Prekop.—*Mela i. c. i. Plin. iv. c. 12.*

TAPIOCA, a species of starch which the Brasilians make from the roots of the cassada plant. See **JATROPHA**.

TAPIR, in zoology, the elephant hog, a genus

of quadrupeds of the order of belluæ, resembling the hippopotamus. The fore feet have each four hoofs; the hind feet three. There is only one species, viz.—**T. Americanus**, the American tapir. The nose of the male extends far beyond the lower jaw, is slender, and forms a sort of proboscis; it is capable of being contracted or extended at pleasure, and its sides are sulcated. The extremities of both jaws end in a point, and there are ten cutting teeth in each. Between them and the grinders there is a vacant space; and there are ten grinders in each jaw. The ears are erect, the eyes small, and the body is shaped like that of a hog. The back is arched; the legs are short; and the hoofs small, black, and hollow. The tail is very small. The animal grows to the size of a heifer half a year old. The hair is short: when young it is spotted with white; when old of a dusky color. They inhabit the woods and rivers of the east side of South America, from the isthmus of Darien to the Amazon. They sleep during day in the darkest and thickest forest adjacent to the banks, and go out in the night time in search of food. They feed on grass, sugar-canes, and fruits. If disturbed they run to the water; and swim very well, or sink below; and, like the hippopotamus, walk on the bottom as on dry ground. They make a sort of hissing noise. This is the largest of the American animals.

TAPLIN (William), an eminent veterinary surgeon. He was one of the first scientific cultivators of his art in England, and contributed not a little to its improvement by his writings. His principal publications are, the *Gentleman's Stable Directory*, or the *Modern System of Farriery*, 1790, 2 vols. 8vo.; *Practical Observations upon Thorn Wounds, Punctured Tendons, and Ligamentary Lameness in Horses, with Instructions for their Treatment and Cure*, 8vo.; and a *Compendium of Experimental Farriery*, originally suggested by Reason and confirmed by Practice, 1796, 8vo. He also published a tract on the *Preservation of Game*; and other pieces. He is said to have been deranged in the latter part of his life owing to domestic misfortunes. He died in London in January 1807.

TAPORICA, or **ITAPORICA**, an island in the Bay of Todos Santos, Brasil, the largest, most populous and fertile, of all those in the bay. This island defends the entrance of the bay; upon the point or extremity is the fort of San Antonio, and a town called Veija, in lat. 13° S.

TAPPAHANNOCK, a port of entry and the capital of Essex, county Virginia, on the southwest bank of the Rappahannock; it is fifty-five miles E. S. E. from Fredericksburg, and fifty north-east from Richmond. Its situation is low and unhealthy. It contains a court-house, a jail, and an Episcopal church. All the shipping belonging to the towns on the Rappahannock is entered at the custom-house of this place.

TAPPING, in general, the act of piercing a hole in a vessel, and applying a tube or canula in the aperture, for the commodious drawing off the liquor contained therein.

TAPPING, in surgery. See **SURGERY**.

TAPSUS. 1. A maritime town of Africa (*Sil. Ital. 3*). 2. A peninsula on the east coast of Sicily.

TAPYRI, an ancient nation, who resided near Ilyrcania.—Dionys. Perieg.

TAQUARI, a river of Brasil, on the borders of Paraguay, which runs a western course from the mountains and falls into the Paraguay opposite the lake of Marmore, by many mouths, the largest of which is in long 54° W., lat. 19° 15' S

TAQUASO, a large river of South America, in the province of Darien. Its course is from north-east to south-west for a great distance, when it turns west and enters the sea in the gulf of San Miguel. Its sands abound in fine gold.

TAQUILE, or TAQUUNA, an island of the great lake of Chucuito, or Titicaca, in the district of the province of Paucarolla, in Peru. In the higher grounds of this island are some plains on which are to be seen the ruins of some large old towns built of stone.

TAR, *n. s. & v. a.* Sax. *taræ*; Belg. *tarre*; Dan. *tiere*. Liquid pitch; the turpentine of the pine or fur drained out by fire; a sailor: to smear with tar: hence to tease; provoke: or, as Johnson thinks, from Gr. *ταρατα*.

Then, foaming *tar*, their brides they would champ, And trampling the fine element would fiercely ramp.

There has been much to do on both sides; and the nation holds it no sin to *tarre* them on to controversy.

Two curs shall tame each other; pride alone Must tar the mastiffs on, as 'twere the bone. *Id.*

A man will not lose a hog for a halpennyworth of tar.

In senates bold, and fierce in war, A land commander, and a *tar*. *Swift's Miscellanies.*

TAR is prepared in great quantities in Norway, Sweden, Germany, Russia, and North America, and in other countries where the pine and fir abound. For the method of obtaining it, see PINUS. Becher, the celebrated chemist, first proposed to make tar from pit-coal. Manufactures for this purpose have been established many years ago in the ci-devant bishopric of Liege, and in several parts of England. In 1781 the earl of Dundonald obtained a patent for extracting tar from pit-coal by a new process of distillation. See CHEMISTRY, Index, and COAL. Tar, which is well known for its economical uses, is properly an empyreumatic oil of turpentine, and has been much used as a medicine both internally and externally. See MATERIA MEDICA and PHARMACY.

TAR WATER, or water impregnated with the soluble parts of tar, was, about a century ago, a very popular remedy; but is now almost entirely out of use.

TARANIS, a name of Jupiter, among the ancient Gauls.—Lucan, i. 146.

TARANTAISE, a province of Sardinia, in Savoy, between Faucigny, Savoy proper, Maurienne, and Aosta. Its superficial extent is about 780 square miles; its surface rugged and uneven, covered with mountains and rocks, and little susceptible of culture. The least sterile parts are brought into surprising cultivation, and made to produce corn, saffron, fruit, and chestnuts: the pastures nourish a fine race of cattle. A number of the inhabitants, however, go out to seek employment in more favored countries. Population 39,000.

TARANTO, or TARENTO, an ancient and considerable town of Naples, in the province of Otranto, eighty miles W. N. W. of the city of that name. It is built on a small island in the great bay called the Gulf of Taranto, and has several advantages as a maritime position, having behind it, towards the north and east, a great maritime inlet called Mare Piccolo (little sea), which extends into the interior, while it communicates with the sea by two channels, one on each side of the island, or rather islet, occupied by the town. Taranto contains 18,500 inhabitants, and has a castle of some strength.

TARANTULA, *n. s.* Ital. *tarantula*; Fr. *tarantule*. An insect whose bite is said to be cured by music.

This word, lover, did no less pierce poor Pyrocles than the right tune of musick toucheth him that is sick of the *tarantula*.

He that uses the word *tarantula*, without having any idea of what it stands for, means nothing at all by it.

TARAS, a son of Neptune, who built Tarentum.

TARAS, an ancient name of Tarentum.

TARASCO, an ancient town of Gaul, now Tarascon.

TARASCON, a considerable town in the south-east of France, on the Rhone, and opposite to the town of Beaucaire, with which it communicates by a bridge of boats. There are manufactures of woollens, silk, stockings, and an export trade in wine, brandy, olive-oil, and other products. Of public buildings the principal is the castle, a structure of hewn stone fortified in the Gothic manner, and surmounted by a platform, affording a fine view of the adjacent country. Some of the churches are likewise handsome. Inhabitants 12,000. Nine miles north of Arles, and fifty-five north-west of Marseilles.

TARAXACUM, in botany, dandelion. See LEONTODON and MATERIA MEDICA.

TARAXIPPUS, a deity worshipped in Elis, who superintended the races and other games. His statue was placed near the race ground, and his protection implored to the horses and their riders.—Paus. vi. 20.

TARBELLE, a name of the Pyrenees, from

TARBELL, an ancient people of Gaul, at the foot of the Pyrenees.—Cæs. de Bell. Gall.

TARBES, an inland town in the south-west of France, and the capital of the department of the Upper Pyrenees, is situated on the left bank of the Adour. It is the see of a bishop, and is surrounded with a wall defended by an old castle. Here are a public square, cathedral, several fine churches, the residence of the bishop, a theatre, and an hospital, and the streets of the town are tolerably broad and well paved. The houses, though low, are not badly built of brick or gray marble, and covered with slate. Here are, also, on a small scale, manufactures of linen, handkerchiefs, paper, knives, and small copper articles. There is here also a royal stud. Inhabitants 8000. On the 20th of March, 1814, the French army under Soult were forced from their position here by the British under the duke of Wellington. Twenty-two milés east by south of Paris.

TARCHON, an Etrurian chief, who assisted Æneas against the Rutuli; and built Tarquinii. Virg. *Æn.* viii. 603.

TARCHONANTHUS, flea-bane, in botany, a genus of plants belonging to the class of syngenesia, and to the order of polygamia æqualis, and in the natural system ranging under the forty-ninth order, composite. The receptacle is villous, and the pappus plumy; the calyx is monophyllous, turbinated, and half divided into seven segments. There are only three species, viz. *T. camphoratus*, *ericoides*, and *glaber*.

TAR'DY, *adj.* & *v. a.* } Lat. *tardus*; Fr. }
TARDIGRA'DOUS, *adj.* } *tardif.* Slow; slug- }
TAR'DILY, *adv.* } gish; dilatory; un- }
TAR'DINESS, *n. s.* } wary: to delay; hin- }
TAR'DITY. } der: tardigradous,

moving slowly: the adverb and noun substantives correspond with tardy.

Nor should their age by years be told,
 Whose souls more swift than motion climb,
 And check the *tardy* flight of time. *Sandys.*

He was indeed the glass,
 Wherein the noble youth did dress themselves;
 Speaking thick, which nature made his blemish,
 Because the accents of the valiant;
 For those that could speak low and *tardily*,
 Would turn their own perfection to abuse,
 To seem like him. *Shakspeare. Henry IV.*

A *tardiness* in nature,
 Which often leaves the history unspoke
 That it intends to do. *Id. King Lear.*

I chose
 Camillo for the minister, to poison
 My friend Polixenes; which had been done,
 But that the good mind of Camillo *tardied*
 My swift command. *Id. Winter's Tale.*

Suppose some observable *tardity* in the motion of light, and then ask how we should arrive to perceive it? *Digby.*

Death he as oft accused
 Of *tardy* execution, since denounced
 The day of his offence. *Milton's Paradise Lost.*

Yield, scoundrel base, quoth she, or die,
 Thy life is mine, and liberty:
 But if thou think'st I took thee *tardy*,
 And dar'st presume to be so hardy
 To try thy fortune o'er afresh,
 I'll waver my title to thy flesh. *Hudibras.*

It is but a slow and *tardigradous* animal, preying upon advantage, and otherwise may be escaped. *Browne.*

The *tardy* plants in our cold orchards placed,
 Reserve their fruit for the next age's taste:
 There a small grain in some few months will be
 A firm, a lofty, and a spacious tree. *Waller.*

When certain to o'ercome, inclined to save,
Tardy to vengeance, and with mercy brave. *Prior.*

If they take them *tardy*, they endeavour to humble them by way of reprisal: those slips and mismanagements are usually ridiculed. *Collier on Pride.*

You may freely censure him for being *tardy* in his payments. *Arbutnot.*

TARE, *n. s.* Dut. *teeren*, to consume.—Skin-ner. A weed that grows among corn.

Through hatred of *tares*, the corn in the field of God is plucked up. *Hooker.*

The liberal contributions such teachers met with, served to invite more labourers, where their seed-time was their harvest; and by sowing *tares* they reaped gold. *Decay of Piety.*

My country neighbours begin not to think of being in general, which is being abstracted from all its in-

ferior species, before they come to think of the fly in their sheep, or the *tares* in their corn. *Locke.*

TARE, or **VETCH**, in botany. See **RURAL ECONOMY**.

TARE, in commerce, is an allowance for the outside package that contains such goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c., that enclose or bind any goods imported loose; or though imported in casks, chests, &c., yet cannot be unpacked and weighed neat.

TARENTINES, the ancient inhabitants of Tarentum, long famous for their bravery, and afterwards equally infamous for their luxury and effeminacy.

TARENTINE WAR, a war which lasted ten years, between the Tarentines assisted by Pyrrhus, and the Romans. See **EPHROSUS**, **ROME**, and **TARENTUM**.

TARENTUM, **TARENTUS**, or **TARAS**, an ancient city of Italy in Calabria, seated near the mouth of the Galesus, and capital of a republic. It was founded by a colony of Spartans, under Phalanthus, about A. A. C. 707. The government was democratical, though they had occasionally some monarchs. It was for some time the residence of Pythagoras, who taught the citizens his philosophy, inspired them with the love of virtue, and rendered them superior to their neighbours, both in the cabinet and the field. They were long independent, and maintained their superiority over thirteen tributary cities; when they could arm 100,000 foot and 3000 horse. Becoming rich, they grew voluptuous and indolent; so that the delights of Tarentum became proverbial. In the pride of their prowess, however, they quarrelled with the Romans, and invited Pyrrhus into Italy. See **ROME**. But the war ended, after ten years, in the total conquest of their republic, its annexation to that of Rome, and the capture of 30,000 prisoners.

TARGE, *n. s.* } Sax. *tarja*; Fr. *targe*; Ital. }
TARGET. } *targa*; Span. *tarja*; Welch, }
TARGETIER } *tarian*; Erse *taargett*. A }
 kind of buckler or small shield borne on the left arm: one armed with a target.

Glancing on his helmet made a large
 And open gash therein, were not his *targe*
 That broke the violence. *Spenser.*

I took all their seven points in my target. *Shakspeare.*

For horsemen and for *targetiers* none could with him compare. *Chapman.*

The arms she useth most is the *target*, to shroud herself under, and fence away the blow. *Hovel's England's Tears.*

Those leaves
 They gathered, broad as Amazonian *targe*. *Milton.*

The Greeks the gates approached, their *targets* cast
 Over their heads, some scaling ladders placed
 Against the walls. *Derham.*

TARGIONIA, in botany, a genus of plants belonging to the class of cryptogamia, and natural order of algæ. The calyx is bivalved, including a globular body. There is only one species, viz.—*T. hypophylla*, the vetch tare, a native of Great Britain. It has leaves about a quarter of an inch long, of a heart-shape, inverted, and growing prostrate in a clump together; their

upper surface is green, covered with whitish papillæ, and their lower surface is black. The fructification grows at the great end of the leaf on the lower side, and consists of two concave valves of a reddish-black color, enclosing a chocolate colored globule, resembling the seed of a tare or vetch, full of a yellow powder. The leaves increase by shooting out young offsets from their sides like the polypus. This plant is found in the north of England, and near Tarbat of Kintyre in Scotland.

TARGUM, תרגום, a paraphrase on the pentateuch in the Chaldee language. It signifies paraphrases or expositions, because they are rather comments and explications than literal translations of the text. They are written in the Chaldee tongue, which became more familiar to the Jews after their captivity in Babylon, than the Hebrew itself. But though the custom of making these expositions in the Chaldee language be very ancient among the Hebrews, yet have they no targums before the era of Jonathan and Onkelos.

i. *The TARGUM OF JERUSALEM* is only upon the Pentateuch; nor is that entire or perfect.

ii. *The TARGUM OF JONATHAN*, the son of Uziel, is upon the greater and lesser prophets. He flourished under Herod the Great, about A. A. C. 30.

iii. *The TARGUM OF JOSEPH THE BLIND* is upon the Hagiographa. This author is much more modern, and less esteemed than those above-mentioned.

iv. *The TARGUM OF ONKELOS* is the most of all esteemed, and copies are to be found in which it is inserted verse for verse with the Hebrew. It is so short and so simple that it cannot be suspected of being corrupted. This paraphrast wrote only upon the books of Moses; and his style approaches nearly to the purity of the Chaldee, as it is found in Daniel and Ezra. This targum is cited in the Mischna, but was not known either to Eusebius, St. Jerome, or Origen. See **ONKELOS**.

TARICHEUM, a fortified town of Judea.—Cicero ad Div. xii. c. 14.

TARIFF, *n. s.* Span. *tarifa*; Fr. *tarif*. A cartel of commerce.

This branch of our trade was regulated by a *tariff*, or declaration of the duties of import and export.

Addison.

TARIF is a table or catalogue containing the names of different sorts of merchandise, with the duties to be paid as settled by authority among trading nations.

TARIN (Peter), a French physician and author, born at Courtenai, about the end of the seventeenth century. He published, 1. *Adversaria Anatomica*, 4to. 2. *An Anatomical Dictionary*, 4to. 3. *Osteographia*, 4to. 4. *Anthropoemia, or the Art of Dissecting*, 2 vols. 12mo. 5. *A Treatise on Ligaments*. 6. *Observations on Medicine and Surgery*, 3 vols. 12mo.: and, 7. *A Description of the Muscles*, 4to. He died in 1761.

TARLETON (Richard), a celebrated English actor, born about the beginning of the sixteenth century at Conover in Shropshire; whence he was brought to London, and patronised by Ro-

bert, earl of Leicester. Stowe says he was one of the twelve whom, in 1583, queen Elizabeth appointed her players at Barn-Elms; allowing them wages and liveries as grooms of the chambers. He wrote a dramatic piece, called *The Seven Deadly Sins*. He died about 1589.

TARN, a fertile department of the south of France, formed of a part of the province of Languedoc, and adjacent to the departments of the Aveyron and Upper Garonne. It has the mountains of Languedoc on the east, and commands, at a distance, a prospect of the Pyrenees; but its whole surface may be termed an undulating plain, traversed by several chains of small hills. Its principal river is the Tarn, a large stream flowing from the north-east to the Garonne. The climate is steady and temperate, and the products are wheat, barley, maize, hemp, flax, vines, and fruit of different kinds. Here are also occasional tracts of fine pasture. Of corn, enough is raised to afford a small annual export. The culture of the vine is extensive; but the wines, with the exception of the kind called *vin du Cog*, do not keep sufficiently to admit of export. Here are, on a small scale, mines of iron and coal; some silk also is cultivated. This department is divided into four arrondissements, viz. Albi (the chief town), Castres, Lavaur, and Gaillac. It has an extent of 2100 square miles, and a population of nearly 296,000, of whom above 40,000 are Protestants.

TARN AND GARONNE, a department in the south of France, formed, so lately as 1808, of portions of the departments of the Lot and Upper Garonne. It lies to the west of the department of the Tarn. Its surface is a plain, traversed by three chains of hills, the highest of which is said not to exceed 1200 feet. Its principal rivers are the Tarn and Garonne. The soil is in general fruitful, and the climate mild, but the labors of the husbandman are frequently exposed to hazard from hail storms. Its products are wheat, barley, maize, hemp, flax, vines, chestnuts, and several fruits of a southern climate, as almonds and figs. The pastures are of limited extent. The domestic animals are mules, asses, horses; poultry is particularly abundant. The culture of silk is on a limited scale. This department is divided into three arrondissements, viz. Montauban (the capital), Moissac, and Castel Sarrazin. It has an extent of 1500 square miles, and a population of 240,000, of whom above 30,000 are Protestants.

TARNISH, *v. a. & v. n.* Fr. *ternir*. To sully; soil; dull: to lose brightness.

Let him pray for resolution, that he may discover nothing that may discredit the cause, *tarnish* the glory, and weaken the example of the suffering.

Collier.

If a fine object should *tarnish* by having a great many see it, or the musick should run mostly into one man's ears, these satisfactions would be made inclosure.

Id. of Envy.

Low waves the rooted forest, vexed, and shed
What of its *tarnished* honours yet remain.

Thomson.

TARNOW, a circle of Austrian Galicia, lying along the river Dunajee, and bounded on the north by the Vistula. Its area is 1300 square

miles, and its population 205,600. It is in general a level country, with the exception of some hills in the south.

TARPAWLING, *n. s.* From *tar*. Hempen cloth smeared with *tar*.

Some the galled ropes with dauby marling bind,
Or scarcloth masts with strong *tarpauling* coats.

Dryden.

Was any thing wanting to the extravagance of this age, but the making a living *tarpaulin* and a swabber the hero of a tragedy?

Dennis.

TARPEIA, a vestal virgin who betrayed the citadel of Rome to the Sabines; for which, by a voluntary mistake, they rewarded her with death. See **ROME**.

TARPEIAN ROCK, in Roman antiquity, a steep rock in Rome; whence, by the law of the XII. tables, those guilty of certain crimes were precipitated. It took its name from *Tarpeia*, who was burnt near it.

TARPEIUS MOUNTAINS, the *Tarpeian Hill*, on which stood the *Tarpeian Rock*. See last article. It was eighty feet perpendicular in height. It was also called *Capitolinus*, from the Capitol being built on it.

TARQUIN I., king of Rome, succeeded *Anacus Martius*, A. A. C. 615. See **ROME**.

TARQUIN II., surnamed the Proud, a tyrant and usurper. See **ROME**.

TARQUINIA, the daughter of *Tarquin I.* and the wife of *Servius Tullius*. After the murder of her husband (see **ROME**), she buried his body, and died of grief the night following. Others say that she was poisoned by the parricide *Tullia*.

TARQUINIENSES, the ancient inhabitants of *Tarquini*. They endeavoured to restore *Tarquin II.* See **ROME**.

TARQUINI, an ancient city of Etruria, built by *Tarchon*, an ally of *Aeneas*. *Lucumo* the Corinthian was educated in it, took his surname *Tarquinius* from it; and after he became king of Rome, by the name of *Tarquin I.*, made it a Roman colony.—*Strabo* 5. It is now called *Tarchina*.

TARQUINIUS (*Lucius Collatinus*), one of the two first consuls of Rome, the husband of *Lucretia* and colleague of *Brutus*. See **COLLATINUS** and **ROME**.

TARQUITUS, a son of *Faunus* and *Dryope*, who assisted *Turnus* against *Aeneas*, and was killed by the latter.—*Virg. Æn. x. v. 550*.

TARRACINA, or *Anxur*, an ancient city of the *Volsci*, between Rome and Naples (see **ANXUR**); now called *Terracina*.

TARRACO, in ancient geography, a city of *Hispania Tarraconensis*, of which it was the capital, founded by the *Phœnicians*; and planted with a Roman colony by the two *Scipiones Africanus*, and seated on the coast of the *Mediterranean*. It is now called *Tarragona*.

TARRACONENSIS HISPANIA, an ancient Roman province of Spain, called also *Hispania Citra*, or *Citerior*, in respect of its situation as to Rome. It was bounded on the north by the *Pyrenees* and the *Cantabrian Sea*, now the *Bay of Biscay*; on the east by the *Mediterranean*; south by *Lusitania*, and *Hispania Bœtica*; and west by the *Atlantic Ocean*. It was famous for

its wines. *Tarraco* was the capital. It comprehended *Catalonia* and some adjacent districts. See **CATALONIA**.

TARRAGONA, a sea-port of *Catalonia*, Spain, near the mouth of the *Francoli*. It is a place of great antiquity, built on a hill, and surrounded by walls with turrets, erected either by the *Moors*, or by the *Christians* of the middle ages. It was occupied by the *British* in the beginning of the eighteenth century, with an intention of rendering it a naval station, but on the acquisition of *Gibraltar*, in 1704, the design was abandoned. *Tarragona* contains 7500 inhabitants, is the see of a bishop, and has a large and elegant cathedral, built in the Gothic style. It was under the *Romans* the chief town of the province of *Tarraconensis*.

TARRANTIUS (*Lucius*), an ancient Roman mathematician and philosopher, who was contemporary with *Cicero*, and was one of his friends. He has been styled the *Prince of Astrologers*. He made two famous horoscopes, the one of *Romulus*, the other of *Rome*.

TARRAS, or **TERRAS**, a volcanic earth used as a cement, and which does not differ much in its principles from *pouzzolana*; but is much more compact, hard, porous, and spongy. It is generally of a whitish-yellow color, and contains more heterogeneous particles, as *spar*, *quartz*, *schorl*, &c., and something more of a calcareous earth. It effervesces with acids, is magnetic, and fusible per se. When pulverised it serves as a cement, like *pouzzolana*. It is found in *Germany* and *Sweden*.

TARRIANCE, *n. s.* From *tarry*. Stay; delay; perhaps sojourn. Obsolete.

Dispatch me hence;
Come, answer not; but do it presently,
I am impatient of my *tarrance*. *Shakspeare.*

TARRIER, *n. s.* Or *terrier*, from *Fr. terre*, the earth. A sort of small dog, that hunts the fox or otter out of his hole.

The fox is earthed; but I shall send my two *tarriers* after him. *Dryden.*

TARRY, *v. n. & v. a.* *Fr. targir*. To stay; to continue in a place; delay; wait; wait for.

Tarry ye here for us until we come again.

Exodus xxiv. 14.

Thou art my deliverer, make no *tarrying*, O God!

Psalms.

Who hath woe and redness of eyes? they that *tarry* long at the wine. *Proverbs* xxiii. 30.

I will go drink with you, but I cannot *tarry* dinner. *Shakspeare.*

Tarry I here, I but attend on death;
But fly I hence, I fly away from life. *Id.*

I yet am tender, young, and full of fear,
And dare not die, but fain would *tarry* here.

Dryden.

TARSEL, *n. s.* Teut. *tarzel*. A kind of hawk.

Hist! *Romeo*, hist! O for a *falc'ner's* voice,
To lure this *tarsel* gentle back again! *Shakspeare.*

A *falc'ner* Henry is, when *Emma* hawks;
With her of *tarsels* and of lures he talks. *Prior.*

TARSUS, *n. s.* *Fr. tarse*; *Gr. ῥαρος*. In anatomy, the space betwixt the lower end of the *foeil bones* of the leg, and the beginning of the five *lool bones* that are joined with, and bear up, the toes.

An obscure motion, where the conjunction is called synanthrosis; as in joining the *tarsus* to the metatarsus. *Wiseman.*

TARSUS, a city of Asia Minor, the ancient capital of Cilicia. It possesses very high antiquity, and is said by Arrian and Strabo to have been founded by Sardanapalus on the same day with Anchiale; others are of opinion that it was a Grecian colony, founded by Tripolemus. It was much favored by Augustus and Adrian, and rose to such celebrity as to rival Athens, Antioch, and Alexandria, in wealth and grandeur, as well as in literature and science. It was also adorned with a number of magnificent temples, a gymnasium, and a theatre. It has, however, been subject to many vicissitudes, and retains scarcely a vestige of its former magnificence.

The city is situated in a fertile plain, on the right bank of the Cydnus; the houses, intersected by gardens and orchards, seldom exceed one story in height, are flat-roofed, and mostly constructed of hewn stone. There is a castle, said to be built by Bajazet; and portions of a wall, probably the remains of that erected by Haroun al Raschid. On an eminence to the south-west are the ruins of a spacious edifice, which may very probably have been the gymnasium; and, about 200 yards farther to the west, an ancient gateway. The city contains two public baths, several mosques, and caravanseraï, and a small ancient church. The land in the neighbourhood is exceedingly fertile. The port is about seven or eight miles from the town. Population 25,000 to 30,000.

TART, *adj.* } Saxon *teart*; Belgic
TARTLY, *adj.* } *taertig*; Gr. *τερω*. Sour;
TART'NESS, *n. s.* } acid; acidulated; sharp;
keen; severe: the adverb and noun substantive corresponding.

Why so *tart* a favour

To trumpet such good tidings? *Shakspeare.*

How *tartly* that gentleman looks!

—He is of a very melancholy disposition. *Id.*

They cannot be too sweet for the king's *tartness*. *Id.*

Figures, with divers coloured earths, under the windows of the house on that side near which the garden stands, be but toys; you may see as good sights in *tarts*. *Bacon's Essays.*

When his humours grew *tart*, as being now in the lees of favour, they brake forth into certain sudden recesses. *Wotton.*

Of these sweets put in three gallons, more or less, into an hogshead, as the *tartness* of your cider requires. *Mortimer.*

TARTAGLIA (Nicholas), a celebrated Italian mathematician, born at Brescia, where he became a famous teacher of the mathematical sciences. He published several works which are esteemed. His chief tract is on number and measure, entitled *Trattat di Numeri et Misura*, 1556, folio. *e* died about 1558.

TARTAK, an idol of the Avites. See **SAMARITANS**.

TARTAN, or **TARTAN CLOTH**, a kind of cloth, made generally of woollen, sometimes of linen, and often of silk, of various colors; as blue, red, green, white, black, and yellow, &c., running in parallel lines and crossing each other; and thus forming various colored squares, paral-

lelograms and parallelopedes. This dress is much worn by the Scottish Highlanders. The tartan dress is said to have been derived from the ancient Gauls or Celtæ; the Galli non-braccati. The tartan is made into plaids, coats, and philibegs. The most elegant form of this dress is when the coat is made of that kind of tartan in which the red stripes chiefly prevail; the vest entirely white; the philibeg, drawers, or trowsers, of that in which the green or blue chiefly predominates; and the plaid, with either the green or blue predominant, but differing from that of the philibeg. See **PHILIBEG**.

TARTAN PLAID. See **PLAID**.

TARTANE, *n. s.* Fr. *tartane*; Ital. *tartana*. A vessel used in the Mediterranean, with one mast and a three-cornered sail.

I set out from Marseilles to Genoa in a *tartane*, and arrived late at a small French port called Cassis. *Addison.*

TARTANE, in sea language, a small coasting vessel navigated in the Mediterranean Sea, and having only one mast and a bowsprit, the principal sail, which is extremely large, being extended by a lateen yard. When tartanes put up a square sail it is called a sail of fortune.

TARTAR, *n. s.* Lat. *tartarus*. Hell. A word used by the old poets. Now obsolete.

With this the damned ghosts he governeth,
And furies rules, and *tartare* tempereth. *Spenser.*

He's in *tartar* limbo worse than hell;
A devil in an everlasting garment hath him,
One worse hard heart is buttoned up with steel.

Shakspeare.

His throne mixed with *tartarean* sulphur. *Milton.*

The spirit of God downward purged
The black *tartareous* cold infernal dregs,
Adverse to life. *Id.*

TARTAR, *n. s.* Fr. *tartre*. The concretion of wine casks; wine lees; see below.

The fermented juice of grapes is partly turned into liquid drops or lees, and partly into that crust or dry feculency that is commonly called *tartar*; and this *tartar* may by the fire be divided into five differing substances, four of which are not acid, and the other not so manifestly acid as the *tartar* itself. *Boyle.*

In fruits, the *tartareous* parts of the sap are thrown upon the fibres designed for the stone, and the oily upon the seed within it. *Grew's Cosmology.*

TARTAR is deposited on the sides of casks during the fermentation of wine; it forms a lining more or less thick, which is scraped off. This is called crude tartar, and is sold in Languedoc from ten to fifteen livres the quintal. All wines do not afford the same quantity of tartar. Neumann remarked that the Hungarian wines left only a thin stratum; that the wines of France afforded more; and that the Rhenish wines afforded the purest and the greatest quantity.

Tartar is distinguished from its color into red and white: the first is afforded by red wine, and is purified from an abundant extractive principle, by processes which are executed at Montpellier and at Venice.

The following is the process used at Montpellier:—The tartar is dissolved in water, and suffered to crystallize by cooling. The crystals are then boiled in another vessel, with the addition of five or six pounds of the white argilla-

ceous earth of Murviel to each quintal of the salt. After this boiling with the earth, a very white salt is obtained by evaporation, which is known by the name of cream of tartar, or the acidulous tartrate of potash.

M. des Maretz has informed us that the process used at Venice consists, 1. In drying the tartar in iron boilers; 2. Pounding it, and dissolving it in hot water, which, by cooling, affords purer crystals; 3. Redissolving these crystals in water, and clarifying the solution by whites of eggs and ashes. The process of Montpellier is preferable to that of Venice. The addition of the ashes introduces a foreign salt, which alters the purity of the product.

TARTAR, in mythology. See **HELL** and **TARTARUS**.

TARTAR, CHALYBEATED. This is prepared by boiling three parts of the supertartrate of potash and two of iron-filings in forty-six parts of water, till the tartar appears to be dissolved. The liquor is then filtered, and crystals are deposited on cooling, more of which are obtained by continuing the evaporation.

TARTAR, CREAM OF, the proper name of the purified supertartrate of potash.

TARTAR, CRUDE, the supertartrate of potash in its natural state, before it has been purified.

TARTAR, EMETIC, the tartrate of potash and antimony. See **ANTIMONY**.

TARTAR OF THE TEETH, the popular name for the concretion that so frequently incrusts the teeth, and which consists apparently of phosphate of lime.

TARTAR, PHENOMENA AND PROPERTIES OF. See **CHEMISTRY**.

TARTAR, REGENERATED, acetate of potash.

TARTAR, SALT OF, the subcarbonate of potash.

TARTAR, SECRET FOLIATED EARTH OF, acetate of potash.

TARTAR, SOLUBLE, neutral tartrate of potash.

TARTAR, VITRIOLATED, sulphate of potash.

TARTARIC ACID. The casks in which some kinds of wine are kept become incrustated with a hard substance, tinged with the coloring matter of the wine, and otherwise impure, which has long been known by the name of argal, or tartar, and distinguished into red and white according to its color. This being purified by solution, filtration, and crystallisation, was termed cream, or crystals of tartar. It was afterwards discovered that it consisted of a peculiar acid combined with potash; and the supposition that it was formed during the fermentation of the wine was disproved by Boerhaave, Neumann, and others, who showed that it existed ready formed in the juice of the grape. It has likewise been found in other fruits, particularly before they are too ripe; and in the tamarind, sumac, balm, carduus benedictus, and the roots of rest-harrow, germander, and sage. The separation of tartaric acid from this acidulous salt, is the first discovery of Scheele that is known. He saturated the superfluous acid, by adding chalk to a solution of the supertartrate in boiling water as long as any effervescence ensued, and expelled the acid from the precipitated tartrate of lime by

means of the sulphuric. Or four parts of tartar may be boiled in twenty or twenty-four of water, and one part of sulphuric acid added gradually. By continuing the boiling, the sulphate of potash will fall down. When the liquor is reduced to one-half, it is to be filtered; and, if any more sulphate be deposited by continuing the boiling, the filtering must be repeated. When no more is thrown down, the liquor is to be evaporated to the consistence of a syrup; and thus crystals of tartaric acid, equal to half the weight of the tartar employed, will be obtained.

The tartaric acid may be procured in needly or laminated crystals, by evaporating a solution of it. Its taste is very acid and agreeable, so that it may supply the place of lemon juice. It is very soluble in water. Burnt in an open fire it leaves a coaly residuum; in close vessels it gives out carbonic acid and carburetted hydrogen gas. By distilling nitric acid off the crystals, they may be converted into oxalic acid, and the nitric acid passes to the state of nitrous.

To extract the whole acid from tartar, M. Thenard recommends, after saturating the redundant acid with chalk, to add muriate of lime to the supernatant neutral tartrate, by which means it is completely decomposed. The insoluble tartrate of lime, being washed with abundance of water, is then to be treated with three-fifths of its weight of strong sulphuric acid, diluted previously with five parts of water. But Fourcroy's process, as improved by Vauquelin, seems still better. Tartar is treated with quicklime and boiling water in the proportion, by the theory of equivalents, of 100 of tartar to thirty of dry lime, or forty of the slaked. A caustic magma is obtained, which must be evaporated to dryness, and gently heated. On digesting this in water, a solution of caustic potash is obtained, while tartrate of lime remains; from which the acid may be separated by the equivalent quantity of oil of vitriol.

According to Berzelius, tartaric acid is a compound of 3.807 hydrogen + 35.980 carbon + 60.213 oxygen = 100; to which result he shows that of M. Gay Lussac and Thenard to correspond, when allowance is made for a certain portion of water, which they had omitted to estimate. The analysis of tartrate of lead gives 8.384 for the acid prime equivalent; and it may be made up of—

3 hydrogen	. =	0.375	4.48
4 carbon	. =	3.000	35.82
5 oxygen	. =	5.000	59.70
		8.375	100.00

The crystallised acid is a compound of 8.375 acid + 1.125 water = 9.5; or in 100 parts 88.15 acid + 11.85 water.

The *tartrates*, in their decomposition by fire, comport themselves like all the other vegetable salts, except that those with excess of acid yield the smell of caramel when heated, and afford a certain quantity of the pyrotartaric acid. All the soluble neutral tartrates form, with tartaric acid, bitartrates of sparing solubility; while all the insoluble tartrates may be dissolved in an excess of their acid. Hence, by pouring gradually an

excess of acid into barytes, strontites, and lime-waters, the precipitates formed at first cannot fail to disappear; while those obtained by an excess of the same acid, added to concentrated solutions of potash, soda, or ammonia, and the neutral tartrates of these bases as well as of magnesia and copper, must be permanent. The first are always flocculent; the second always crystalline; that of copper alone is in a greenish-white powder. It likewise follows, that the greater number of acids ought to disturb the solutions of the alkaline neutral tartrates, because they transform these salts into bitartrates; and on the contrary they ought to affect the solution of the neutral insoluble tartrates, which indeed always happens, unless the acid cannot dissolve the base of the tartrate. The order of apparent affinities of tartaric acid are, lime, barytes, strontites, potash, soda, ammonia, and magnesia.

The tartrates of potash, soda, and ammonia, are not only susceptible of combining together, but also with the other tartrates, so as to form double or triple salts. We may thus easily conceive why the tartrates of potash, soda, and ammonia, do not disturb the solutions of iron and manganese; and on the other hand disturb the solutions of the salts of barytes, strontites, lime and lead. In the first case, double salts are formed, however small a quantity of tartrate shall have been employed; in the second no double salt is formed unless the tartrate be added in very great excess.

The tartrates of lime and barytes are white, pulverulent, and insoluble.

Tartrate of strontian, formed by the double decomposition of muriate of strontian and tartrate of potash, according to Vauquelin, is soluble, crystallisable, and consists of 52.88 strontian, and 47.12 acid. That of magnesia forms a gelatinous or gummy mass.

Tartrate of potash, the tartarized kali of the London college, and vegetable salt of some, formerly called soluble tartar, because much more so than the supertartrate, crystallises in oblong squares, bevelled at the extremities. It has a bitterish taste, and is decomposed by heat, as its solution is even by standing some time. It is used as a mild purgative.

The supertartrate of potash, already mentioned at the beginning of this article, is much used as a cooling and gently opening medicine, as well as in several chemical and pharmaceutical preparations. Dissolved in water, with the addition of a little sugar, and a slice or two of lemon-peel, it forms an agreeable cooling drink by the name of imperial: and if an infusion of green balm be used, instead of water, it makes one of the pleasantest liquors of the kind with which we are acquainted. Mixed with an equal weight of nitre, and projected into a red-hot crucible, it detonates, and forms the white flux; treated in the same way with half its weight of nitre, it forms the black flux; and simply mixed with nitre, in various proportions, it is called raw flux. It is likewise used in dyeing, in hat-making, in gilding, and in other arts.

The blanching of the crude tartar is aided by boiling its solution with one-twentieth of pipe-

According to the analysis of Berzelius, it consists of 70.45 acid + 24.8 potash + 4.75 water = 100; or—

2	primes acid	=	16.75	70.30
1	potash	=	5.95	24.95
1	water	=	1.125	4.75
			23.825	100.00

sixty parts of water dissolve four of bitartrate at a boiling heat; and only one at 60° Fahrenheit. It is quite insoluble in alcohol. It becomes very soluble in water, by adding to it one-fifth of its weight of borax; or even by the addition of boracic acid. It appears by Berzelius that neutral tartrate of potash, dried in the sun, differs from the bitartrate, in containing no water of crystallization. He states it to be compounds of 58.69 acid + 41.31 potash = 100; which afford 155.7 tartrate of lead. Now, 8.375 : 5.95 : : 58.5 : 41.5; which are the equivalent proportions.

On considering the great solvent property of cream of tartar, and that it is even capable of dissolving various oxides, which are insoluble in tartaric acid, as the protoxide of antimony, M. Gay Lussac has recommended it as a useful agent in chemical analysis. He thinks that in many cases it acts the part of a single acid. According to this view, tartar emetic would be a compound of the cream-tarter acid, and protoxide of antimony. Cream of tartar generally contains from three to five per cent. of tartrate of lime, which are in a great measure separated when three parts of tartar are boiled with one of borax for a few minutes in a sufficient quantity of water. The soluble cream of tartar which is obtained by this process is deliquescent; it dissolves in its own weight of boiling water, at 54.5°, and in half its weight of boiling water. Its solution is very imperfectly decomposed by the sulphuric, nitric, and muriatic acids. Four parts of tartar and one of boracic acid form a permanent saline compound, very soluble in water. Alum also increases the solubility of tartar.

By saturating the superfluous acid in this supertartrate with soda, a triple salt is formed, which crystallises in larger regular prisms of eight nearly equal sides, of a bitter taste, efflorescent, and soluble in about five parts of water. It consists, according to Vauquelin, of fifty-four parts tartrate of potash, and forty-six tartrate of soda; and was once in much repute as a purgative by the name of Rochelle salt, or sel de Seignette.

The tartrate of soda is much less soluble than this triple salt, and crystallises in slender needles or thin plates.

The tartrate of ammonia is a very soluble bitter salt, and crystallizes easily. Its solution is spontaneously decomposable. This too forms, with tartrate of potash, a triple salt, the solution of which yields, by cooling, fine pyramidal or prismatic efflorescent crystals. Though both the neutral salts that compose it are bitter, this is not, but has a cooling taste. See SALT.

TARTARINE. The name given by Kirwan to the vegetable alkali, or potash.

TARTARUM. See MATERIA MEDICA.

TARTARUS, in the mythology, the infernal regions, or the hell of the ancient Greeks, Romans, and Egyptians; which consisted of two divisions, the one called Elysium, for the reception of the virtuous; the other Tartarus, for that of the wicked. See ELYSIUM and HELL. Tartarus was surrounded with a brazen wall, and its entrance was continually hidden from the sight by a cloud of darkness three times more gloomy than the obscurest night. Hesiod says (Theog. 720) it was a prison, at a greater distance from the earth than the earth is from the heavens. Virgil says (*Æn.* vi.) it was surrounded by three impenetrable walls, and by the impetuous burning streams of the river Phlegethon. The entrance was by a large lofty tower, whose gates were supported by columns of adamant, which neither gods nor men could open. In Tartarus, he adds, were punished all who had been disobedient to parents, traitors, adulterers, barbarous conquerors, who undertook unjust and cruel wars, faithless ministers, &c. It was the place where Tantalus, Ixion, Sisyphus, the Danaïdes, and other heinous offenders were punished (*Ovid. Met. iv. fab. 13, Hom. Odys. xi.*); and was frequented by the Furies, the Harpies, and other monsters of the heathen mythology.

TARTARY, a name applied very indefinitely to an extensive region of central Asia, and interposing between Asiatic Russia on the north, and the great empires of Persia, Hindostan, and China, on the south. The Tartar race was known and celebrated in antiquity under the name of Scythians, a people who are described under the same warlike, rude, and pastoral features which now distinguish the tenants of these regions. The simplicity of their manners, their ignorance of money and of luxury, and their hospitality, caused them to be quoted with admiration by the Greek sages: at the same time, the records of history bear ample testimony to the calamities which their inroads inflicted. Even under the Assyrian dynasty, they are represented as having overwhelmed and held the sceptre of Western Asia for twenty-eight years. If we may believe Herodotus, Cyrus, after having subdued the rest of Asia, found the termination of his life in his conflict with Tomyris, queen of this race. Darius, his successor, with difficulty escaped the same fate, and Alexander was little more fortunate; for, though he compelled the Scythians to cross the Jaxartes, he in vain attempted to pursue them beyond it.

At these earlier periods, although the Scythian tribes frequently laid waste the southern empires, they were unable to effect any permanent conquest or settlement. It was during the decline of the Roman empire that these tribes began permanently to forsake their own plains, in search of more fertile regions, and the first of these ravagers, whose terror and fame reached the frontier of Italy, were the Huns, the ancestors of the modern race of Mongols. The deformity of their aspect, and the ferocity of their manners, rendered their name more terrible than that of any of the German barbarians, and under Attila, characterised as 'the scourge of God, and the destroyer of nations,' they materially hastened the

downfall of the empire. On the eastern frontier, another Tartar race took no less active a part. The Turks or Toorks, inhabiting extensive tracts of what is now called Chinese and Independent Tartary, poured down in large bodies upon the Persian empire, where they established a dynasty, under the name of Seljukian; and ultimately established themselves at Constantinople. In the twelfth century Tartary became the seat of the most formidable and extensive empire that perhaps has ever been established. Zingis, originally an obscure chief, having succeeded in uniting under his standard all the neighbouring tribes, successively conquered China, Persia, and all Central Asia, from the Black Sea to the Eastern Ocean. His successors added Russia, and overran Poland, with part of Germany. For some time the greatest panic prevailed in Europe. But in the course of a few reigns this vast empire was split into parts. The lead was now taken by the populous countries on the Oxus and the Jaxartes, where Timur established a sway, which, though less extended than that of Zingis, was superior in the value and importance of its regions. Timur conquered all Persia, broke the power of the Turks in Asia Minor, and established in India a dynasty, which continued to reign, and to form the most splendid court of Asia, till the close of the last century. China has also always been subject to Tartar dynasties.

Tartary may now be considered as divided into Chinese and Independent Tartary. The latter, since the time of Timur, has been occupied, and the ancient inhabitants either exterminated or expelled by the Uzbecks, a people of the widely extended race of Turk or Toork, but whose original seat is not precisely ascertained. It has the country of Bulkh (part of Cabul) and Korassim on the south; the Caspian on the west; and Asiatic Russia on the north. The Uzbecks, like other Turks, are celebrated in the east for their beauty, the reputation of which, however, arises chiefly from its contrast to the hideous forms of the Mongols, Calmucs, and other Tartar tribes. They have broad foreheads, high cheek bones, thin beards, and small eyes: their complexion is clear and ruddy, their hair generally black. The political constitution is a complete and pure despotism, the will of the sovereign being the only law. This circumstance depends probably upon the military habits formed by conquest; and according to which, and to the forms and customs of a camp, the whole government is administered. In Bokhara the men are divided, like troops, into parties or masses of ten each, who have a boiler, a tent, and a camel in common. The authority of the sovereign is also strengthened by the Mahometan religion, which is here professed in its utmost rigor. The Koran is implicitly assumed as the guide, not only in faith and doctrine, but in civil government and domestic life. The king, now reigning at Bokhara, was raised to the throne by the ostentatious profession of poverty, and of all those observances which establish the character of a Mussulman saint. Even in his present elevation, he spends part of every day in teaching the Mahometan religion, and of every night in watching and prayer. The revenue is col-

lected exactly in the proportions prescribed in the Koran; and one-tenth of it is expended in alms.

All the habitations of the Uzbecks consist of a species of moveable tent called *onool*, composed of a lattice of thin lath, covered with black felt. From twenty to fifty of these compose a species of moveable village or camp. Many of them now, however, reside in towns. Horsemanship is their favorite pursuit, and their horses are considered, next to the Arabian, as the best in Asia. An immense exportation formerly took place to India. In this trade, horses are still purchased in the markets of Bokhara or Bulkha, where they cost from £5 to £100, and are fattened on the way in the rich pastures of Cabul. Horse flesh, and koumiss, or fermented mares' milk, are considered as the greatest of luxuries here; in regard to which last even the Mahometan law is obliged somewhat to relax its rigor. Horses are so numerous that there is scarcely a man so poor as to walk; even beggars travel on horseback, or at least on camels or asses. As might be expected in a people with these habits, the Uzbecks produce numerous bodies of light cavalry, and excel in predatory warfare. Their arms are a long and heavy lance, swords, and a shield; but many have long knives and daggers. They charge in a body, with shouts, which are described as terrific. In battle they are drawn up in three lines, so that, even after being repulsed, they return twice to the charge. Their laws of war are most barbarous, giving no quarter except to infidels, whom the Koran allows them to sell as slaves; while the faithful, who cannot thus be subjected, have the honor of being killed on the spot. Yet, compared with many other Asiatics, they are sincere and honest, and murder scarcely ever occurs. Foreign merchants are also protected and encouraged, notwithstanding the national bigotry.

Bokhara may be considered as the most important of the kingdoms into which Independent Tartary is now divided. This territory includes the finest part of the country on the banks of the Oxus, and, though not very extensive, maintains an army of 80,000 or 100,000 cavalry. The city of Bokhara contains upwards of 100,000 inhabitants, with very extensive establishments for the cultivation of learning; and Samarcand, though declined from its ancient splendor, contains many fine buildings, and exhibits the same beauty of climate and situation for which it was anciently celebrated. The present possessor has paid much attention to it. On the Jaxartes, the bey of Koukan or Ferganna, possesses an extensive, fertile, and highly populous kingdom. The cities of Koukan, Khojund, and Murghelan, are said in populousness and beauty of situation to surpass any other in Central Asia. The population generally retains its pastoral and migratory habits, more particularly as we proceed northwards among the Kirghises. The country on the Upper Oxus, and that between the Aral and the Caspian, consists almost entirely of a vast sandy desert, tenanted by roving tribes of Uzbecks and Turcomans, who subsist partly by pasturage, and partly by plunder. Even here, however, are a few richer tracts, on which towns are built.

Chinese Tartary.—The tracts of Central Asia, over which the Chinese empire holds a nominal sway, include the whole territory contained between Hindostan and Asiatic Russia, and from the Eastern Ocean to the mountain boundary of Independent Tartary; a space comprising about 70° of longitude, and 20° of latitude. The southern and mountainous part of this vast tract passes under the name of Thibet. The western part of what is usually called Chinese Tartary is among the regions of the globe with regard to which our information is most imperfect. The great emporium of this region is Yareund, situated to the south, and forming the rendezvous of the merchants from India, Cabul, and Independent Tartary. Proceeding eastward, the principal kingdoms are Koten or Khoten, and Hami or Chamil. The former is represented as very flourishing, containing numerous fortified cities, and excelling both in agriculture and manufactures. It is particularly celebrated for a species of beautifully variegated marble, which bears a high price in China. Hami is also described as a wealthy region, inhabited by a dissolute people. In this part of Asia are mentioned Acsu, Cialis, Ciarcian, Lop, and Peym: but one of its most distinguishing features is the great desert of Shamo or Cobi, which extends from west to east through nearly its whole extent. It extends in this direction nearly 2000 miles, and cannot be crossed without almost insuperable difficulties. Yet its position is such as to make it impossible to avoid it, on going from Cashgar to China. The caravans therefore coast its northern border, till they come to Lop, where they cross from north to south, and proceed to China along the south border.

Tartary, to the west and north-west of China, consists entirely of naked plains, particular portions only of which afford pasture and water, and traversed by wandering tribes. All of them own the supremacy of the Chinese empire, though it is necessary to secure their allegiance by giving pensions to chiefs. At the same time these wandering tribes claim the right of making war upon each other, though, when these contests rise to an alarming height, a Chinese force is employed to suppress them. All these people are devoted to Shamanism, or the religion of the Lamas; and in each distinguished place there is a sovereign priest, who claims the privilege of immortality and pre-existence.

The eastern extremity of Tartary, bordering on the Pacific, consists of the country of the Mantchoo Tartars, which, in consequence of having given a dynasty to China, forms now a province of that empire. It is still a favorite hunting residence of the emperors. The country consists generally of lofty mountains, covered with immense forests. No grain except oats can be raised; and, though the latitude be only that of the south of France, the climate resembles that of Norway. The most valued production is ginseng, a medicinal plant which grows on the declivity of wooded mountains, or on the rocky banks of deep rivers. The root is the part used in physic, and the value of it is enhanced by its age. In China it is highly esteemed. The persons who collect it carry with them neither horses,

baggage, tent, nor even a bed. They have merely a bag of dried millet, and lodge at night under the shelter of trees, or in temporary huts. Their greatest danger is from wild beasts, with which every part of the country is infested. The Mantchoo Tartars in person resemble the Mongols, except that they are fairer. They have adopted, only to a very limited extent, the religion of Fo or Boodh, but have an ancient religion of their own, and a language peculiar to themselves. Their country is traversed by the river Amour or Saghalien, which, in the upper part of its course, forms the boundary of the Chinese and Russian empires. Besides these tribes, who inhabit the region properly called Tartary, a great part of the southern provinces of Asiatic Russia have a Tartar population, among these may particularly be distinguished the Kalmucs and Baschkirs.

TARTINI (Joseph), a celebrated Italian musician, born at Pisano, in Istria, in 1692. He became so capital a performer on the violin, that he was appointed master of the band in the famous church of St. Anthony. He published several valuable tracts on music; and is styled by Dr. Burney, the Admirable. He died 1770.

TARTRATE. A neutral compound of tartaric acid with a base.

TARUFFI (Emilio), an eminent Italian painter, born at Brescia, in 1632. His landscapes and historical pieces were much admired, as well as his choice of scenery. He died in 1694.

TARVISIUM, an ancient town of Italy, now Treviso.

TARUNTIUS (Spurina, Lucius), a celebrated mathematician, who flourished about A. A. C. 61. Cic. ad div. ii. c. 47.

TARUSATES, an ancient people of Gaul, who inhabited the country now called Tursan. Cæs. de Bel. Gal. iii. 23.

TARUSCUM, an ancient town of Gaul.

TASK, *n. s.* & *v. a.* } Fr. *tasche*; Ital. *tassa*; }
 TASKER, *n. s.* } Lat. *taxo*. Something }
 TASKMASTER. } imposed by another to }
 be done; employment: 'to take to task' is to re- }
 prove; reprimand: to task, to impose a burden }
 or business upon another: the noun-substantives }
 that follow corresponding.

Forth he goes,
 Like to a harvestman, that's *tasked* to mow,
 Or all, or lose his hire. *Shakspeare. Coriolanus.*

I have drunk but one cup to night, and that was
 craftily qualified too; and behold what innovation it
 makes here. I am unfortunate in the infirmity, and
 dare not *task* my weakness with any more.

Id. Othello.

All is, if I have grace to use it so,
 As ever in my great *taskmaster's* eye. *Milton.*

Relieves me from my *task* of servile toil
 Daily in the common prison else enjoined me. *Id.*

Divert thy thoughts at home;
 There *task* thy maids, and exercise the loom. *Dryden.*

Hear, ye sullen powers below;
 Hear, ye *taskers* of the dead. *Id. and Lee.*

A holy man *took* a soldier *to task* upon the subject
 of his profession. *L'Estrange.*

The service of sin is perfect slavery; and he who
 will pay obedience to the commands of it, shall find

it an unreasonable *taskmaster*, and an unmeasurable
 exactor. *Smith.*

He discovered some remains of his nature when he
 met with a football, for which Sir Roger took him to
task. *Addison.*

His mental powers were equal to greater *tasks.*
Atterbury.

No happier *task* these faded eyes pursue,
 To read and weep is all they now can do. *Pope.*

TASSEL, *n. s.* Fr. *tasse*; Swed. *tass*; low
 Lat. *tasselus*. An ornamental bunch of silk or
 glittering substances.

Their heads are tricked with *tassels* and flowers.
Sandys.

Then took the squire an horn of bugle small,
 Which hung adown his side in twisted gold
 And *tassels* gay. *Spenser.*

Early, ere the odorous breath of morn
 Awakes the slumbering leaves, or *tasselled* horn
 Shakes the high thicket, haste I all about. *Milton.*

TASSIE (James), modeller, born near Glas-
 gow, of obscure parents, began his life as a
 country stone mason. Going to Glasgow, he
 acquired a knowledge of drawing in the acad-
 emy instituted by the Fowlises; while, at the
 same time, he was obliged to labor at stone cut-
 ting for his support. Resorting to Dublin for
 employment, he became known to Dr. Quin,
 who was amusing himself with trying to imitate
 the precious stones in colored pastes, and take
 impressions of the engravings that were on them.
 Dr. Quin soon discovered Tassie to be one in
 whom he could place perfect confidence. He
 was endowed with fine taste; modest, unassum-
 ing, patient, and possessed the highest integrity.
 The doctor committed his laboratory and ex-
 periments to his care. The associates were fully
 successful; and found themselves able to imitate
 all the gems, and take accurate impressions of
 the engravings. The doctor, when the discovery
 was completed, encouraged Mr. Tassie to repair
 to London, and to devote himself to the prepa-
 ration and sale of those pastes as his profession.
 In 1766 he arrived in the capital; and until his
 death, in 1799, he continued acquiring eminence
 and wealth. In addition to this elegant art, he
 practised the modelling of portraits in wax, which
 he afterwards moulded and cast in paste.

TASSISUDON, or TADISSOO JEUNG, a city of
 Northern Hindostan, the capital of the province
 of Bootan, and residence of the Deb Rajah,
 stands in a highly cultivated valley, about three
 miles in length, by one in breadth; intersected
 by the Tehintchiew River. On the surrounding
 mountains are timber trees, intermixed with fir
 and pine, and a great variety of shrubs. The
 climate generally is described as remarkably sa-
 lubrious.

The castle or palace of Tassisudon is situated
 near the centre of the valley, and is a quadrang-
 ular building of stone. The walls are thirty feet
 high, pierced below with very small windows,
 apparently more for the purpose of admitting air
 than light. The citadel is very lofty, consisting of
 seven stories, each from fifteen to twenty feet high.
 From the centre rises a square piece of masonry,
 which supports a canopy of copper richly gilt,
 supposed to be immediately over the idol Maha
 Moonee. The Deb Rajah of Bootan dwells in
 the citadel, on the fourth story from the ground.

Near to the city are a long line of sheds, where the workmen are employed in forging brazen gods, and various other ornaments of their religious edifices. There is here also a considerable manufacture of paper, made from the deah bark, which grows in great abundance near to Tassison. It is very strong, and capable of being woven, when gilt, into the texture of silks and satins.

TASSO (Bernard) an illustrious Italian lawyer, descended of the ancient and noble family of Torreggiani. He was author of several ingenious compositions in verse and prose. He was sent to accompany the prince of Salerno upon a deputation from Naples, to the emperor Charles V., to remonstrate against the erection of an Inquisition there. He was afterwards employed by William Gonzago, duke of Mantua, as his principal secretary, who at last promoted him to be governor of Ostiglia, upon the Po; where he died in 1585. He was father to the celebrated Torquato.

Tasso (Torquato), a justly celebrated Italian poet, born at Sorrento in Naples, in the year 1549, the son of Bernard, by Portia di Rossi, a lady of an illustrious family of Naples. At nine he and his father were condemned to death for treason, but escaped; and three years after they went from Rome to Mantua: Tasso had then completed his knowledge of the learned languages. He was soon after sent to the university of Padua; and, in his eighteenth year, published his *Rinaldo*. He next went to Bologna, by the invitation of the city and college; but soon returned to Padua at the request of Scipio Gonzago, who had been elected prince of the academy then established by the name of the *Ætheroi*, of which Tasso was made a member. Here he formed the plan of his *Jerusalem Delivered*. Being pressed by the duke, and his brother cardinal Lewis, to reside with them at Ferrara, he consented, and the duke gave him an apartment in his palace, where he lived in affluence, and prosecuted his work; which he dedicated to the duke. When he was about twenty-seven, he published a pastoral comedy called *Aminta*. In his thirtieth year, he finished his *Jerusalem*, and, the whole being reprinted and published together, its success was astonishing, and it was immediately translated into Latin, French, Spanish, and even the oriental languages. But it was Tasso's fate to become wretched as soon as he gained the summit of reputation. Soon after his *Jerusalem* was published, he lost his father; his *Jerusalem* was attacked by invidious critics; and the perfidy of a friend drew upon him greater misfortunes. In consequence of a rencontre, in which he behaved very bravely, the duke put him in prison, under pretence of securing him from any future attacks. But Tasso within a year escaped, and retired to Turin, where he was recommended to the duke of Savoy; but Tasso, fearing that the duke of Ferrara would require him to be delivered up, set out for Rome: there he was visited by princes, cardinals, prelates, and all the learned in the city. But, being impatient of exile, he made his peace with the duke, who gave him fresh marks of his esteem. But Tasso, having made some attempts

on the duke's sister, princess Leonora, whom he had celebrated in his verses, the duke caused him to be confined in the hospital of St. Anne, as a person deranged. Tasso applied to the duke, by every friend he had, to release him, but without effect; for Tasso was certainly disordered in his mind. At last, after he had been a prisoner seven years, Vincent Gonzago, prince of Mantua, came to Ferrara, during the festivals, procured his liberty, and took him to Mantua, he being then in the forty-second year of his age. At Mantua he lived about a year in great favor with the prince, but he became weary of a state of dependence, and therefore resolved to go to Naples, and endeavour to recover his mother's jointure, which had been seized by her relations when he went into exile. Finding his law-suit not likely to be soon determined, he went from Naples to Rome, where he continued about a year in high favor with pope Sixtus V., and then went to Florence, at the invitation of Ferdinand, grand duke of Tuscany. Having spent another year at Florence, he returned to Naples, and published his *Jerusalem Delivered*. Soon after this Sixtus V. died, and was succeeded by Clement VII.; and his nephews, Cynthio and Peter Aldrobandini, were created cardinals. Cynthio, who was a patron of learning, prevailed with him to leave Naples, and live with him in Rome. He returned again to Naples, but came back to Rome, in order to be crowned with laurels in the capital. While they were waiting for fair weather, Cynthio fell sick; and, before he recovered, Tasso was taken ill, and died on the fifteenth day, aged fifty-one. His poems had acquired him an immortal reputation. His works were printed together at Florence in 1724, in 6 vols. folio, with the criticisms. His *Aminta* and *Jerusalem Liberata* have been translated into English.

TASSONI (Alexander), an Italian poet, born at Modena, in 1565. He was a member of the academy of Umeristi; and, among other works, published *Secchia Rapita*, or the *Rape of the Bucket*: which was the first model of a Mock Heroic poem in the Italian language. He died in 1635.

TASTE, <i>v. a., v. n., &</i>	} Fr. <i>taster</i> , to try; Ital. <i>tastare</i> ; Teut. <i>tasten</i> ; barb. Lat. <i>tasto</i> . To perceive, distinguish, or try, by the palate; have perception of food; relish: hence to eat a small quantity; to relish mentally; obtain pleasure from: as a verb neuter to try by the mouth; to eat; have a smack; be tintured; enjoy in a small degree: as a noun substantive the act of tasting; gust; perception; sensibility; a crude portion or specimen; intellectual relish or discernment; an essay; trial: the adjectives correspond with the above terms: a taster is one who takes the first portion of food: tastlessness, insipidity; want of relish or perception.
TAST'ABLE, <i>adj. [n. s.]</i>	
TAST'ED,	
TAST'ER, <i>n. s.</i>	
TASTE'FUL, <i>adj.</i>	
TASTE'LESS,	}
TASTE'LESSNESS, <i>n. s.</i>	

Manna was like coriander seed, white; and the taste of it was like wafers made with honey.

Exodus xvi. 31.

The ruler of the feast *tasted* the water made wine.

John ii.

He should *taste* death for every man. *Heb. ii. 9.*

The *tasting* of death touched the righteous also, and there was a destruction of the multitude in the wilderness.

Wisdom.

Seeing they pretend no quarrel at other psalms which are in like manner appointed to be daily ready, why do these so much offend and displease their *tastes*?

Huober.

Roscetes was seldom permitted to eat any other meat but such as the prince before *tasted* of.

Knolles.

I have almost forgot the *taste* of fears :

The time has been, my senses would have cooled
To hear a night shriek.

Shakspeare. Macbeth.

Cowards die many times before their deaths,
The valiant never *taste* of death but once.

Shakspeare.

I hope, for my brother's justification, he wrote this as an essay or *taste* of my virtue.

Id.

When king feed upon wild garlick, their milk *tasteth* of it.

Bacon.

Bees delight more in one flower than another and therefore have *taste*.

Id. Natural History.

Coleworts prosper exceedingly, and are better *tasted*, if watered with salt water.

Id.

They thought 't not safe to resolve, till they had *taste* of the people's inclination.

Id. Henry VII.

The body's life with meats and air is fed,
Therefore the soul doth use the *tasting* power

In veins, which, through the tongue and palate spread,

Distinguish ever relish sweet and sour.

Davies.

So shalt thou be despised, fair maid,

When by the sated lover *tasted* ;

What first he did with tears invade,

Shall afterwards with scorn be wasted.

Carew.

Fair hope! our earlier heaven! by thee

Young time is *taster* to eternity.

Crashaw.

Musick of sighs thou shalt not hear,

Nor drink one lover's *tasteful* tear.

Cowley.

Bold deed to *taste* it, under ban to touch.

Milton.

Delicacies of *taste*, sight, smell.

Id.

Best of fruits, whose *taste* gave elocution.

Id.

Sion's songs to all true *tastes* excelling,

Id.

Where God is praised aright.

Of nature's bounty men forbore to *taste*,

And the best portion of the earth lay waste.

Waller.

The tardy plants in our cold orchards placed,

Reserve their fruit for the next age's *taste*.

Id.

By deparating chemical oils, and reducing them to an elementary simplicity, they could never be made *tasteful*.

Boyle.

Their distilled oils are fluid, volatile and *tasteable*.

Id.

Besides the prayers mentioned, I shall give only a *taste* of some few recommended to devout persons in the manuals and offices.

Stillingfleet.

Thou and I marching before our troops,
Mav *taste* fate to them, mow them out a passage.

Dryden.

This fiery game your active youth maintained,
Not yet by years extinguished, though restrained ;

You season still with sports your serious hours,

For age but *tastes* of pleasures, youth devours.

Id.

Says the fly, Are not all places open to me ?

Am not I the *taster* to princes in all their entertainments.

L'Esrange.

Though there be a great variety of *tastes*, yet, as in smells, they have only some few general names.

Locke.

If by his manner of writing a critic is heavy and *tasteless*, I throw aside his criticisms.

Addison's Spectator.

As he had no *taste* of true glory, we see him equipped like an Hercules, with a club and a lion's skin.

Addison.

The understanding cannot, by its natural light, discover spiritual truths ; and the corruption of our will and affections renders them *tasteless* and insipid to us.

Rogers's Sermons.

Your way of life, in my *taste*, will be the best.

Pope.

Not *tasteful* herbs that in these gardens rise,
Which the kind soil with milky sap supplies,
Can move.

Id.

Scholars, when good sense describing,

Call it *tasting* and imbibing.

Swift.

How ill a *taste* for wit and sense prevails in the world!

Id.

Pleasure results from a sense to discern, and a *taste* to be affected with, beauty.

Seed's Sermons.

Apicius, here, the *taster* of the town,

Feeds twice a-week, to settle their renown.

Young.

However contradictory it may be in geometry, it is true in *taste*, that many little things will not make a great one.

Reynolds.

TASTE is a certain sensation, or class of sensations, excited in the mind by certain bodies, which are called *sapid*, applied to the tongue and palate, and moistened with the saliva. This is the original and proper meaning of the word *taste* (see METAPHYSICS); but, as the qualities of bodies which produce these sensations are unknown, they have in all languages got the names of the sensations themselves, by that figure of speech which substitutes the cause for the effect. Hence we talk of the taste of sugar, wormwood, honey, vinegar, &c.; and say that the one is sweet and the other sour, &c. Tastes have been divided into simple and compound; and philosophers have to very little purpose endeavoured to ascertain the number of each species. See Phil. Trans. No. 280, 299; and Abercromb. Nov. Med. Clavis.

TASTE is likewise used in a figurative sense to denote that faculty of the mind by which we perceive and enjoy whatever is beautiful or sublime in the works of nature or of art. Like the taste of the palate, this faculty relishes some things, is disgusted with others, and to many is indifferent; and from these obvious analogies between it and the external sense it has obtained its name. It has likewise been called an internal sense, and by Dr. Hutchinson a reflex sense; whilst others have considered it, not as a distinct faculty or sense, but as the joint exertion of perception and judgment in some cases, and as a play of the imagination in others.

TASTELESS EARTH (agust erde), the name given by professor Trommsdorff to a new simple earth, which he discovered in the Saxon beryl. It is distinguished, he says, from other earths by being white, and totally insoluble in water. In a fresh state, when moistened with water, it is somewhat ductile. In the fire it becomes transparent, and very hard, so as to scratch glass, but remains insipid and insoluble in water. The burnt earth dissolves very easily in acids, and produces with them peculiar salts, which are entirely devoid of taste; and hence he gave it the name of tasteless earth. Fixed alkalis do not dissolve this earth, either in the dry or in the wet way; and it is equally insoluble with

the carbonic acid and with caustic ammonia. It has a greater affinity to the oxalic than to the other acids.

TATA, or Dotis, a large town of Western Hungary, situated on a height in the midst of marshes, sixty-four miles E. S. E. of Presburg. It contains 8600 inhabitants, and is divided into two parts called Dotis and Tovaros. The inhabitants carry on a number of employments on a small scale, such as the manufacture of woollens, sawing of timber, and, finally, the preparing of whetstones for sale and export. They are descended from a mixed race of Magyars, Slavonians, Geiman settlers, and Jews. In religion the Catholic predominates, and here are a Catholic gymnasium and monastery, conducted by the Piarists.

TATARBASAR, or TATAR BAZARGIK, a considerable inland town of European Turkey, in Bulgaria, near the Marizza; the ancient Hebrus. It is situated on the great road from Constantinople to Belgrade, and is little visited by travellers; but is said to contain several mosques, baths, and other good buildings, with about 10,000 inhabitants. Fourteen miles N. N. W. of Philippopoli.

TATE (Nahum), a poet, born at Dublin, where he received his education, in 1652. He was made poet laureat to king William III. upon the death of Shadwell, and held that place until the reign of George I., whose first birthday ode he wrote, with unusual spirit. He died in the mint in 1716. He wrote nine dramatic performances, a great number of poems, and a version of the psalms in conjunction with Dr. Nicholas Brady.

TATIAN, a writer of the primitive church, in the second century, born in Assyria, and trained up in the heathen religion and learning. He became Christian and disciple of Justin Martyr, whom he attended to Rome; and, while Justin lived, continued orthodox; but after his death made a schism, and founded a new sect, condemning marriage, enjoining abstinence from wine and animal food, and suffering only water to be used in the holy mysteries; whence his followers were called Encratite and Hydroparastatæ. None of his works are extant but his piece against the Gentiles, entitled his Oration to the Greeks.

TATIENSES, a name given by Romulus to a tribe of the Roman people, in honor of his colleague king Tattius, to whom part of them had been subjects. They lived on the mounts Capitulinus and Quirinalis.

TATIUS (Titus), king of the Sabines and Romans. See **ROME** and **SABINES**.

TATIUS (Achilles), a native of Alexandria, was the author of a book on the sphere. There is also attributed to him a Greek romance on the lives of Leucippe and Clitophon, of which Salmassius has given a beautiful edition in Greek and Latin, with notes. Suidas says that Tattius was a Pagan, but afterwards became a Christian, and a bishop. Photius mentions him in his Bibliotheca.

TATTA, a large district of Hindostan, in Sinde, comprehending the whole Delta of the Indus, calculated at 150 miles in length, by fifty

in breadth. Being intersected by rivers, travelling takes place mostly by water. The country is in general sandy and barren, and many parts of it only fit for pasturing camels or goats; but it also produces a quantity of rice and salt, and the rivers abound with fish. This district has for nearly forty years belonged to the Amers of Sinde. Its principal town is Tatta, and its chief port Corachie. In the beginning of the eighth century this province was invaded by the Arabs, and may be considered as having been subject to the Mahometans from that period. It was taken possession of by the emperor Akbar in 1590, and acknowledged the Mogul authority till the dissolution of that empire. Its former capital was Brahminabad, which is said to have been enclosed by a brick wall, having 1400 round towers or bastions.

TATTA, an ancient city, capital of the above-mentioned district, is situated on the banks of the Indus, about 130 miles from the sea. The town stands in a fertile valley, formed by a range of low hills, which, during the freshes of the river, is inundated; a circumstance which often gives the city the appearance of an island. Some of the houses are of brick and mortar, but the greater number are of mud and timber. The old English factory, purchased in 1751, is still reckoned the best house in the town. The circumference of the modern town is four miles, and is supposed to contain 15,000 inhabitants. It was formerly famous for its commerce and manufactures; but its greatness is much diminished. On a hill, about a mile from the town, is an immense number of Mahometan tombs, in good preservation. The stone mausoleum of Mirza Isa is uncommonly magnificent and well executed; and supported by many columns: the interior is covered with inscriptions formed of different colored stones. The modern city of Tatta was founded by Jam Mundel, the 14th of the Soomeah dynasty, A. D. 1485, and was plundered by the Portuguese in 1555. Dr. Robertson was of opinion that Tatta was the Pattala of the Greeks.

TATTER, *v. a. & n. s.* } Sax. *totapan*. To
TATTERDEMAL'ION. *n. s.* } tear; rend; make
ragged: a rag; a fragment: tatterdemalion seems
a word formed in the caprice of ridicule.

Through *tattered* cloaths small vices do appear:
Robes and furred gowns hide all.

Shakspeare. King Lear.

This fable holds, from him that sits upon the throne,
to the poor devil that has scarce a *tatter*.

l'Étrange.

As a poor fellow was trudging in a bitter cold morning with never a rag, a spark that was warm clad called to this *tatterdemalion*, how he could endure this weather?

Id.

Where waved the *tattered* ensigns of Ragfair,
A yawning ruin hangs.

Pope.

Little tyrants raged,
Tore from cold wintry limbs the *tattered* weed.

Thomson.

Here Satan vanished—He had fresh commands,
And knew his pupil was in able hands;
And now, the treasure found, and matron's store,
Sought other objects than the *tattered* poor.

Harte.

TATTERSHALL, a market-town and parish in Gartree hundred, Lincolnshire, on the river

Bain, eight miles S. S. W. from Horncastle, and 128 north of London. The church is a handsome building formerly collegiate in the form of a cross; some of the windows still contain some good paintings on glass. The castle was demolished during the civil war. The Bain is navigable for barges to the Witham. Market on Friday. Fairs, May 11th, and September 25th. It is a curacy.

TATTLE, *v. n. & n. s.* } Belg. *tateren*; Goth. }
 TATTLER, *n. s.* } *tatala*. To prate; talk idly; use many words with little meaning: idle talk an idle talker.

He stands on terms of honourable mind,
 Ne will be carried with every common wind
 Of court's inconstant mutability,
 Ne after every *tattling* fable fly. *Spenser.*
 The one is too like an image, and says nothing;
 and the other too like my lady's eldest son, evermore
tattling. *Shakspeare.*
 Going from house to house, *tattlers*, busy bodies,
 which are the canker and rust of idleness, as idleness
 is the rust of time, are reproved by the apostle.

Taylor.
 Excuse it by the *tattling* quality of age, which is
 always narrative. *Dryden.*
 The world is forward enough to *tattle* of them.

Locke.
 The French language is extremely proper to *tattle*
 in; it is made up of so much repetition and compli-
 ment. *Addison.*

They asked her how she liked the play?
 Then told the *tattle* of the day. *Swift's Miscellany.*
 A young academick shall dwell upon trade and
 politicks in a dictatorial stile, while at the same time
 persons well skilled in those different subjects hear
 the impertinent *tattle* with a just contempt.
Watt's on the Mind.

TATTOO, *n. s.* Fr. *tapotez tous*. The beat
 of drum by which soldiers are warned to their
 quarters.

All those whose hearts are loose and low,
 Start if they hear but the *tatto*. *Prior.*

TATTOOING or TATTOWING, an operation
 in use among the islanders in the South Sea for
 marking their bodies with figures of various
 kinds which they consider as ornamental. It is
 performed by puncturing the skin and rubbing a
 black color into the wounds. See OTAHETE.

TAVAI POENAMMOO, an island in the South
 Pacific Ocean, being the most southerly of the
 two which form New Zealand, and separated from
 the northern island by a channel called Cook's
 Straits, discovered by captain (then lieutenant)
 Cook, who sailed round them both in the year
 1769. It is about 500 miles in length from
 south-west to north-east, and from 55 to 140
 broad. See ZEALAND, NEW.

TAVARONE (Lazarus), a celebrated Italian
 painter of history and portraits, born at Genoa in
 1556. He was a disciple of Luke Cangiagio,
 and succeeded him as painter to the king of
 Spain. He died in 1631.

TAUBMAN (Frederick), a learned German
 critic born in Franconia, about 1565. He be-
 came professor of poetry and belles lettres at
 Wirtemberg. He published Commentaries on
 Virgil and Plantus. He died in 1633.

TAVERNIER (John Baptist), a famous
 French traveller, born at Paris in 1605. In the

course of forty years he travelled six times to
 Turkey, Persia, and the East Indies; and visited
 all the countries in Europe, travelling mostly on
 foot. His Travels have been often printed. He
 died on his journey, at Moscow, in 1699.

TAV'ERN, *n. s.* } Fr. *taverne*; Lat. *taberna*.
 TAV'ERNER, } A house where wine is
 TAV'ERNKEEPER, } sold, and drinkers are en-
 TAV'ERNMAN. } tertained: the other names
 mean the person who keeps a tavern.

Enquire at London, 'mong the *taverns* there
 For there they say he daily doth frequent,
 With unrestrained loose companions.

Shakspeare. Richard II.
 After local names, the most in number have been
 derived from occupations; as tailor, archer, *taverner*.
Camden.

To reform the vices of this town, all *taverns* and
 alehouses should be obliged to dismiss their company
 by twelve at night, and no woman suffered to enter
 any *tavern* or alehouse. *Swift.*

TAVISTOCK, a borough and market-town in
 Tavistock hundred, Devonshire, near the river
 Tavy, fourteen miles north from Plymouth, and
 206 west by south of London. The manufac-
 ture principally occupying the inhabitants is that
 of serges. This town is well built, but the
 streets are narrow, and indifferently paved. The
 church is large and handsome. It is one of the
 stannary towns. The ruins of its benedictine
 abbey are still observable. It sends two mem-
 bers to parliament, the right of election being in
 the freeholders, inhabitants of the borough;
 number of voters about 110; the returning offi-
 cer is the portreeve. Here is a chalybeate mi-
 neral water. Market on Saturday. Fairs, Janu-
 ary 17th, May 6th, September 9th, October 10th,
 and December 11th. It is a vicarage. Patron,
 the duke of Bedford.

TAUNT, *v. a. & n. s.* } Fr. *tanser*.—Skinner.
 TAUNTINGLY, *adv.* } Mr. Thomson observes
 that taunt, in sea language, signifies too high or
 lofty (contracted from too haught). To reproach;
 insult; revile; treat with insolence: the reproach
 used; insult; scoff: the adverb corresponding.

When I had at my pleasure *taunted* her,
 She in mild terms begged my patience. *Shakspeare.*
 With scoffs and scorns, and contumelious *taunts*,
 In open market-place produced they me,
 To be a publick spectacle. *Id. Henry VI.*

It *tauntingly* replied
 To the 'discontented members, the' mutinous parts,
 That envied his receipt. *Id. Coriolanus.*

The bitterness and stings of *taunting* jealousy,
 Vexatious days, and jarring joyless nights,
 Have driven him forth. *Rove's Jane Shore.*

Julian thought it more effectual to persecute the
 Christians by *taunts* and ironies than by tortures.

Government of the Tongue.
 He, by vile hands to common use debased,
 Shall send them flowing round his drunken feast,
 With sacrilegious *taunt* and impious jest. *Prior.*

TAUNTON, a market-town and borough of
 Somerset, is situated on the river Tone; and, in
 point of size, buildings, and general respectabil-
 ity, may vie with many cities. It extends
 nearly a mile from east to west, and consists of
 four principal streets, with various minor ones.
 The streets are wide and airy; the houses very
 well built, and most of them have gardens be-

hind. Within the last twenty years the town has undergone many alterations and improvements, in most of which, views of utility have been judiciously combined with embellishment. The vale of Taunton, or Taunton Dean, is proverbial for its fertile soil and temperate climate. The public buildings are the market-house, town-hall, free grammar school, and the parish churches, St. Mary Magdalen's and St. James's. St. Mary's is an elegant and splendid building, situated near the centre of the town, built in the Gothic style of architecture; whence it has been supposed to have been founded by Henry VII., as were several other churches in Somersetshire. It is extremely spacious and beautiful, and at one end here is a lofty tower of magnificent workmanship. It contains thirteen windows, adorned with a variety of curious ornaments. The height of the whole is 153 feet; and from the balustrades at the bottom of the pinnacles there is an extensive view of the adjacent country. The roof is extremely curious, and is supported by twenty-four pillars in four rows, which divide the whole into five aisles and a chancel. In the centre stands the desk and pulpit, beautifully adorned with carved work. In the middle aisle, over the pillars, are twelve niches, supposed to have been occupied with the images of the apostles. There are no less than forty-four windows in this church, some of which still retain traces of the ancient painting. The church of St. James is a plain ancient building, which seems to have been erected in the thirteenth century. Besides the parish churches, there are several dissenting meeting-houses in the town. Paul's meeting-house is perhaps the oldest. The Baptist chapel is a large, expensive, and handsome building, fifty-four feet in length, and forty-nine in breadth; the roof is supported by two strong and curious pillars of the Corinthian order. The pulpit and staircase are enriched with elegant carved work; and the fronts of the galleries and pews are of Flemish oak. The Octagon chapel, erected by the Rev. Mr. Wesley, in 1778, is a neat building in Middle Street, St. James's. The Wesleyan Methodists have another chapel in Upper High Street, built by Mr. James Lackington, the late bookseller, Finsbury Square, London. The Baptists have also another chapel in Silver Street, which is a small neat structure. The Quaker meeting-house is a neat building, kept extremely clean, and the Catholics have a respectable chapel in the Crescent. The market-house stands in the centre of the town, and is a handsome and commodious building: in the lower part is the town-hall, and a coffee-room furnished with newspapers, &c. On the first floor there is an elegant assembly-room, fifty-feet long, and thirty wide, in which hang two superb chandeliers, presented to the inhabitants by the late colonel Coxe. In the upper floor is a handsome room, supplied with a billiard-table. On each side of this house is a large wing or arcade, for the accommodation of those who attend the markets with poultry, butter, and other articles of provisions. The corn-market is held in one of the arcades. In front is a spacious area, on which are erected moveable stalls, placed in rows, for the use of the butchers. This area is

enclosed by posts and chains. In the middle of it, to the north, is a noble pavement of broad stones, 216 feet in length, and eighteen broad, which is called the Parade.

The free grammar-school was founded in the reign of Henry VII., by Fox, bishop of Winchester, and liberally endowed, about the year 1553, by William Walbee. The charitable institutions in Taunton consist likewise of several alms-houses, two work-houses, and an hospital or infirmary. Taunton hospital is an oblong building, situate in East Reach, and was erected by subscription in 1811, to commemorate the jubilee kept in honor of his late majesty's having attained the fiftieth year of his reign. The building (erected about fifty years ago for the purpose of an hospital) has been converted into a convent, and is now inhabited by nuns of the order of St. Bridget, who came into England during the revolution in France. Part of the castle of Taunton remains. It was originally built by Ina, king of the West Saxons. The principal part of the castle, as formerly laid out, was the great hall, which is 119 feet and a half long, by thirty feet and a half broad, and twenty feet five inches high. It is now the place in which the Lent assizes, the county sessions, and the courts of the bishops of Winchester, are held. The assize-hall, and some other parts of this building, were repaired, and elegantly fitted up, in the end of the last century, by Sir Benjamin Hammet, member for the borough.

On the north side of the town stands the Priory farm, near to which there was once a priory of black canons, which was founded by William Gifford, bishop of Winchester, in the reign of Henry I. Besides this, there were several chapels and chantries in Taunton, all of which were dependent on the mother church, in the convent dedicated to St. Peter and St. Paul. Taunton carries on some manufactures, and a considerable trade to Bridgewater by means of the Tone. It was for a long period the principal seat of the manufacture of coarse woollen goods, such as serges, corduroys, sagathies, druggets, shalloons, &c., a manufacture which flourished here soon after its introduction into England. For many years, however, it has been on the decline; and the inhabitants are at present occupied in a great measure in the silk trade. Large quantities of malt liquor are sent from this town to Bristol. Taunton is a borough by prescription, its rights being confirmed by charter at a very early period. In the reign of Charles II. it was deprived of its charter on account of its adherence to the parliament: but he restored its privileges about seventeen years after. About 1792 the corporate body was dissolved, and the charter lost, on account of the number of members having been allowed to decrease below a majority of the whole. In the adjoining village of Wilton there is a bridewell, built and maintained by the county, for the confinement of criminals only, debtors being sent to the county jail at Hchester. Taunton sends two members to parliament, who are elected by such of the inhabitants residing within the borough as do not receive alms, and are potwallers or potwallopers, that is, every inhabitant who dresses his own victuals. The

number of voters is about 500. The legal returning officers of this borough are the bailiffs, elected at the annual court leet, as was decided by a committee of the house of commons on the 3d of May 1803. Numerous Roman coins have been found in this neighbourhood, and it is certain that it was a place of some note in the time of the Saxons, from the circumstance of king Ina building his castle here. Markets on Wednesday and Saturday, which are very considerable. Thirty-one miles north-east of Exeter, and 140 west by south of London. Population 8534.

TAUNTON, a post-town and capital of Bristol county, Massachusetts, on the river Taunton, twenty-one miles east of Providence, twenty-four north of Bristol, twenty-seven north by west of New Bedford, and thirty-two and a half south of Boston. It is a pleasant and handsome town, containing a court house, a jail, town house, bank, academy, printing office, paper mill, three rolling and slitting mills, two cotton manufactories, and five houses of public worship, two for Congregationalists, two for Baptists, and one for Friends. Large quantities of bricks are made in this neighbourhood.

TAURÆ, in zoology (from Lat. *taurus* a bull, literally a female bull, differing from *vacca*, a cow), the name given by the Romans to that hermaphrodite kind of ox which is neither bull nor cow, and which British farmers call a freemartin. See HERMAPHRODITE.

TAURANIA, a town of Italy, in the country of the Brutii.—Lempriere.

TAURANTES, an ancient people of Armenia, who dwelt between Artaxata and Tigranocerta.—Tacit. Ann. 14, c. 24.

TAURI, an ancient nation of European Sarmatia, who inhabited Taurica Chersonesus, and sacrificed all strangers to Diana. The statue of this goddess, which they believe to have fallen down from heaven, was carried off to Sparta by IPHIGENIA and ORESTES. See these articles.—Herodot. iv. c. 99. Eurip. Iphig. &c.

TAURIC (from Taurica), of or belonging to, or produced in Taurida, or Taurica Chersonesus. The term is chiefly applied to animals, natives of that country; particularly the Tauric goats, from the skins of which the celebrated Morocco leather is manufactured at Karasubazar, a town in Taurica.

TAURIC GOAT'S LEATHER, or Morocco Leather, is the staple of an ancient manufacture, in Karasubazar, where they make large quantities from the skins of the numerous flocks of Tauric goats. They begin the process by cleaning the skins in the following manner:—After having steeped some raw hides in cold water for twenty-four hours, to free them from blood and other impurities, the fleshy parts are scraped off with proper instruments. They are next macerated for ten days in cold lime water, to loosen the hair, which is likewise scraped off as clean as possible. For fifteen days they lie in clean cold water, and then are worked under foot in a succession of clean water; the last being impregnated with dog's dung to loosen the hair still more, when they receive a second scraping, and are drained of their humidity; which finishes the cleaning process. They now proceed to what

they call feeding the skins, by steeping them four days in a cold infusion of wheat bran; then in a decoction of honey and water, twenty-eight pounds to five pails, cooled down to the temperature of new milk; out of which they are put under press into a vessel with holes at the bottom to let the liquor escape. They are lastly steeped four days in a light solution of salt and water, one pound to five pails; this finishes the preparation, and the leather is now ready to receive the dye. A strong decoction of *artemisia annua*, or southern-wood, in the proportion of four pounds to ten pails of water, seems to be the basis of all the different colors that they give to Morocco in Taurica, Astracan, and the other cities formerly belonging to the Tartar empire, where the secret has remained till now. When a red color is intended, a pound of cochineal in powder is gradually stirred into ten pails of fine yellow decoction of *artemisia*, and boiled up in it for half an hour, with five or six drachms of alum, and poured on the leather in a proper vessel. They are next worked under foot in an infusion of oak leaves in warm water, till they become supple and soft; when they are finally rinsed in cold water, then rubbed over with olive-oil and calendered with wooden rollers; which finishes the manufacture. The yellow Morocco is dyed with the decoction of *artemisia* alone; only stronger; twenty pounds of it to fifteen pails, being the proportion when used without other admixture; but two pounds of alum in fine powder are gradually added, by half a table spoonful at a time; and with this each skin is twice stained before the last operation of oiling and calendering. It is proper to remark that there is a little difference in the preparation of the skins for receiving the pure yellow dye described above, as neither honey nor salt are used; but, instead of them, the hides are steeped for two days in an infusion of oak-leaves; and immediately after being taken out of the infusion of bran wherein they must have lain four days, and then be worked under foot for a few hours of these four days, next rinsed in cold water, and placed one above another on poles, to drain off the water and make them ready for staining.

TAURICA, in the mythology, a surname of Diana, because she was worshipped by the inhabitants of Taurica Chersonesus.

TAURICA CHERSONESUS, in ancient geography a large peninsula of Europe, at the south west end of the Palus Mæotis, joined to Scythia by an isthmus, and bounded by the Cimærian Bosphorus, the Euxine Sea, and the Palus Mæotis. The inhabitants were called Tauri, and were very savage. Strabo, iv. Plin. iv. 12. Its modern name, till lately, was Crimea, or Crim Tartary. See TARTAR and TARTARY. The inland country was anciently possessed by the Scythians, who extended themselves on the north beyond the Perekop, west to the Dnieper, and east as far as the Don. The west and south coasts were inhabited by some Greek colonies, of which the town of Chersonesus became the most powerful. The east side on the Don and the opposite country, or the tract from the Don along the sea of Azoph to the Black Sea and Mount Caucasus, was under the kings of the

Bosphoric Greeks, so called from the strait of Bosphorus. The Scythians proving troublesome neighbours to the Greeks, they asked the assistance of Mithridates VII. king of Pontus, who drove the Scythians out of the peninsula, and formed the kingdom of Bosphorus, which comprehended the whole peninsula, and the country facing it on the east towards Mount Caucasus. In the reign of Dioclesian, the Sarmatæ were in sole possession of this kingdom, except that the Goths had seized a part of it, on the west side of the peninsula, and the whole tract lying north of it, along the Don. The peninsula afterwards fell under the emperors of the east, though partly shared with the Huns; who were succeeded by the Cozars, and these by the Polawzers. About the end of the twelfth century, the Genoese, having made themselves masters of the Euxine or Black Sea, with all its harbours, settled also in the Crimea. In the thirteenth century the Tartars expelled the Polawzers out of the Crimea; but the strength of the Genoese ports and castles baffled their undisciplined fury; and held out till 1471, when the Turks reduced the whole Crimea and placed a khan over it. In 1698 the Russians made an attempt on the Crimea, but took only Perekop. In 1736 they were more successful under count Munich, who again took Perekop, and opened a passage into the Crimea, though garrisoned by 100,000 men in a great number of strong towers. In 1737, 1738, and 1739, the Russians renewed their invasion with such success, that they ravaged one-half of the Crimea, while the Tartars ravaged the other; and vast numbers of the people perished by famine. The khan, however, continued after this to govern the greater part of it; and assumed the title of Khan of Lesser Tartary, though he was only a vassal of the Ottoman Porte, till 1774, when he was declared independent. But in 1783, from the farther successes of the Russians, under Catherine II., he abdicated his government, and ceded the whole country to Russia.

TAURICA CHERSONESUS, in modern geography, is the ancient name restored to the Crimea, by the late empress of Russia, Catherine II., after her complete conquest of the whole country. It is also called Taurida, Tauris, and Russian Tartary, and simply Taurica. In the Russian language it is called Tauricheskaia.

TAURICORNOUS, *adj.* Lat. *taurus* and *cornu*. Having horns like a bull.

Their descriptions must be relative, or the *tauricornous* picture of the one the same with the other.

Browne.

TAURIDA, a province of European Russia, which lies between long. 31° 36' and 40° 24' E., and between lat. 44° 32' and 47° 50' N.; has a superficial extent of 35,000 square miles; but the inhabitants are so thinly scattered that their number does not exceed 260,000, making hardly seventy-four to the square mile. It contains some fertile tracts, particularly in the Crimea, but has also immense steppes, many of them almost entirely unproductive, and all deficient in water, though others are covered with the finest grass. The summer is mild, but the winter, though short, is very severe. Without any particular insalubrity of climate, a species

of scurvy, common in this country, is more prevalent here than in other parts of the south of Russia. In the peninsula a regular system of agriculture is carried on; but, throughout the rest, little is to be found except wandering tribes. The principal products have been described under the head of CRIMEA. The inhabitants consist of a mixture of Tartars of three or four different tribes, Cossacs of two or three, Russians, Jews, gypsies, and foreign colonists, chiefly of German descent. The province is divided into six circles, besides the isle of Taman, and the land of the Czernomorski Cossacs.

TAURIDA. This is also the name of a range of mountains, which sweep along the whole coast of the Crimea from east to west. They are apparently distinct from the great chains of Europe and Asia; the highest, the Tschatyrdag, is about 6800 feet above the Euxine. They are composed of sand, lime-stone, and marl-slate. In the Isle of Taman, at the eastern extremity of the peninsula, is a volcano in this line of mountains, which broke out for the first time in 1804. These mountains divide the Crimea into two parts, remarkable for difference of climate; the northern, by much the larger, being neither pleasant nor healthy, while the southern, which may be said to resemble in its degree of heat, and in its vegetable products, the most favored parts of Asia Minor.

TAURINI, the ancient inhabitants of

TAURINUM, a town of Gallia Cisalpina; (Sil. Ital. iii. 646, Plin. iii. 17), now called Turin.

TAURIS, a city of Persia, which at different periods has been the capital of the empire. Sir William Jones and other writers conceive it to be the ancient Ecbatana. D'Anville, however, imagines it to be Gaza, or Ganzaca, where Cyrus deposited the treasures of Cræsus. It was a favorite city of Haroun el Raschid; and, according to Persian tradition, was founded by Zobeida, one of his wives. It was probably to him that it was indebted for that extraordinary magnitude and splendor which it once exhibited. In the time of Chardin, it was reckoned to contain upwards of 500,000 inhabitants, and carried on an extensive trade with Russia, Tartary, and India; and, for the accommodation of strangers, there were 300 spacious caravanseras. The manufacture of silk, particularly of turbans, was very extensive. Tauris, however, has suffered in a more than ordinary degree under those revolutions which have laid waste all the modern cities of Persia. Situated near the frontier, it has alternately been the object of contest to Turks, Tartars, and Persians, and has been taken and sacked eight different times. It has suffered still more by earthquakes. The last, in 1724, is supposed to have destroyed 100,000 inhabitants. At present Tauris does not contain more than 30,000 people, and is, on the whole, one of the most wretched cities in Persia. The wall that surrounds it is decayed; and, while the ruins of the ancient city cover a great extent of ground, they exhibit nothing but a confused heap of old mud walls. Long. 46° 37' E., lat. 38° 10' N.

TAUROMENIUM, or TAUROMINIUM, an ancient town of Sicily, between Messina and

Catana; built by the Zancleans, Sicilians, and Hybleans, by order of Timoleon, in the age of Dionysius II. tyrant of Syracuse. The hills adjacent were famous for their grapes and wines; and for the extent and beauty of their prospects. Diodor. It was built on the site of Naxos, and is now called Taormina. See NAXUS, and TAORMINA.

TAUROMINIUS, a river near Taurominium. TAURUS, in astronomy, one of the twelve signs of the zodiac.

TAURUS, the name which Europeans give to a lofty chain of mountains, situated in the eastern part of Asia Minor, where it borders on Syria, called by the Turks Gebel Kurin. They approach so near to the Mediterranean as in some places to leave only narrow passes, the most celebrated of which is that of Issus, where the battle was fought between Darius and Alexander. These mountains are in many places very rugged, and covered with vast pine forests. They are traversed in summer by Turcoman shepherds, who in winter descend and take up their residence in towns.

TAUSENAU. See DAUSENAU.

TAUTOL'OGY, *n. s.* Fr. *tautologie*; Gr. *ταυτολογία*; *ταῦτο* and *λόγος*. Repetition of the same words, or of the same sense in different words.

All science is not *tautology*; the last ages have shewn us, what antiquity never saw, in a dream.

Glanville's Scepais.

Saint Andre's feet ne'er kept more equal time,
Not even the feet of thy own Psyche's rhyme;
Though they in numbers as in sense excel,
So just, so like *tautology*, they fell. *Dryden.*

Every paper addressed to our beautiful incendiaries hath been filled with different considerations, that enemies may not accuse me of *tautology*.

Addison's Frecholder.

TAW, *n. s.* Perhaps from Sax. *τavian*, to whiten. A marble to play with.

Trembling I've seen thee
Mix with the children as they played at wax;
Nor fear the marbles as they bounding flew,
Marbles to them, but rolling rocks to you. *Swift.*

TAW'DRY, *adj.* From St. Audry, St. Awdrey, or St. Etheldred, as the things bought at St. Etheldred's fair.—Henshaw and Skinner. Meanly showy; fine without grace; showy without elegance. It is used both of persons and things.

Bind your fillets fast,
And gird in your waste,

For more fineness, with a *tawdry* lace.

Spenser's Pastorals.

Not the smallest beck,
But with white pebbles makes her *tawdry* eyes
neck. *Drayton.*

He has a kind of coxcomb upon his crown, and a few *tawdry* feathers. *L'Estrange.*

Old Romulus, and father Mars, look down!
Your herdsman primitive, your homely clown,
Is turned a beau in a loose *tawdry* gown.

Dryden's Juvenal.

He rails from morning to night at essenced fops
and *tawdry* courtiers. *Addison's Spectator.*

A clumsy beau makes his ungracefulness appear
the more ungraceful by his *tawdriness* of dress.

Clarissa.

TAWEETAWEE. A cluster of islands, nearly sixty in number, in the eastern seas, form-

ing part of the Sooloo Archipelago. Some are of considerable extent, others high, some low, and not a few mere rocks. The chain of islands to the south-east of Taweetawee are all low, with an infinite number of shoals between them, which abound with fish, and are the site of a pearl fishery. The island of Taweetawee has plenty of excellent waters, but very few inhabitants; the names of many of these small islands in the Malay language are so indecent that they do not admit of being translated.

TAWING. See TANNING.

TAW'NY, *adj.* Fr. *tané*, *tanné*. Yellow; tan-colored; like things tanned.

This child of fancy, that armado knight,

For interim to our studies shall relate,

In high born words, the worth of many a knight
From *tawny* Spain, lost in the world's debate.

Shakspeare.

Eurus his body must be drawn the colour of the
tawny Moor, upon his head a red sun. *Peacham.*

The *tawny* lion pawing to get free.

Milton.

Whilst they make the river Senaga to bound the
Moors, so that on the south side they are black, on
the other only *tawny*, they seem not to derive it from
the sun. *Browne.*

Where 's the worth that sets this people up

Above your own Numidia's *tawny* sons?

Addison's Cato.

TAX, *n. s. & v. a.* Fr. *taxer*; Belg. *taxe*,

TAXATION, *n. s.* Lat. *taxo*; Welsh *lâsg*. An

TAX'ER } impost or tribute imposed;

an excise; a tallage; charge; censure: to impose a tribute or charge; to censure: taxation is the act of doing so; impost: taxer, he who taxes.

Jehoiakim gave the silver and gold to Pharaoh,
but he *taxed* the land to give the money.

2 Kings, xxiii. 35.

The subjects could taste no sweeter fruits of having a king, than grievous *taxations* to some vain purposes; laws made rather to find faults than to prevent faults.

Sidney.

I bring no overture of war, no *taxation* of homage; my words are as full of peace as matter.

Shakspeare. Twelfth Night.

How many lath he killed? I promised to eat all of his killing.—Niece, you *tax* signior Benedick too much; but he'll be meet with you. *Shakspeare.*

I am not justly to be *taxed* with any presumption for meddling with matters whrein I have no dealing.

Raleigh.

These rumours begot scandal against the king, taxing him for a great *taxer* of his people.

Bacon's Henry VII.

They cannot *tax* others' omissions towards them without a tacit reproach of their own.

Decay of Piety.

He could not without grief of heart, and without some *tax* upon himself and his ministers for the not executing the laws, look upon the bold licence of some pamphlets.

Clarendon.

Tax not divine disposal: wisest men
Have erred, and by bad women been deceived.

Milton.

Men's virtues I have commended as freely as I have *taxed* their crimes.

Dryden.

If he *taxes* both of long delay,
My guilt is less, who sooner came away. *Id.*

With wars and *taxes* others waste their own,
And houses burn, and household gods deface,
To drink in bowls which glittering gems chase *Id.*

This salutation cannot be *taxed* with flattery, since it was directed to a prince, of whom it had been happy for Rome if he had never been born, or if he had never died.

Addison.

The *tax* upon tillage was two shillings in the pound in arable land, and four in plantations: this *tax* was often levied in kind upon corn, and called *decumæ* or tithes.

Arbutnot.

Various news I heard,

Of old mismanagements, *taxations* new;

All neither wholly false nor wholly true.

Pope.

TAXATIO ECCLESIASTICA. The valuation of ecclesiastical benefices made through every diocese in England, on occasion of pope Innocent IV. granting to king Henry III. the tenth of all spirituals for three years, was first made by Walter, bishop of Norwich, delegated by the pope to this office in 38 Hen. III. This taxation is sometimes called *Pope Innocent's Valor*, and *Taxatio Norwicensis*.

In 1288 pope Nicholas IV. granted the tenths to king Edward I. for six years, towards defraying the expense of an expedition to the Holy Land; and, that they might be collected to their full value, a taxation by the king's precept was begun in that year (1288), and finished as to the province of Canterbury in 1291, and as to that of York in the following year; the whole being under the direction of John, bishop of Winton, and Oliver bishop of Lincoln. A third taxation, entitled *Nova Taxatio*, as to some part of the province of York, was made A. D. 1318 (11 Ed. II.) by virtue of a royal mandate directed to the bishop of Carlisle, chiefly on account of the invasion of the Scots, by which the clergy of those border countries were rendered unable to pay the former tax.

The taxation of pope Nicholas is important, because all the taxes, as well as our kings as to the popes, were regulated by it, until the survey made in the twenty-sixth year of Henry VIII.; and because the statutes of colleges which were founded before the Reformation are also interpreted by this criterion, according to which their benefices under a certain value were exempted from the restriction in the statute 21 Hen. VIII. c. 13 concerning pluralities. Various detached parts of this record had been published in county histories; but the whole was for the first time given to the public in 1802, under the direction of the commissioners on the public records, from two MSS. in the king's remembrancer's office, exchequer, collated with a Cottonian MS. of much greater antiquity in the British museum, Tiberius C. X. which has unfortunately suffered, some damage from the fire which happened to the Cottonian library whilst lodged at Westminster. By a strange carelessness in the introductory note to the volume, published under such high authority, mention is made of pope Innocent XXII. instead of pope Innocent IV.

A new *Valor Beneficiorum* was instituted in 26 Hen. VIII., when the first-fruits and tenths of every ecclesiastical promotion were annexed to the revenue of the crown, by stat. 26 Hen. VIII. c. 3. To ascertain their value, ecclesiastical surveys were taken by virtue of commissions in the king's name issuing under the great seal, 26 Hen. VIII.; and these surveys, preserved in

the first-fruits office, are admitted as evidence of the amount at that period, although they are generally considered as estimating the value much too low. These surveys are commonly called 'The King's Books,' according to which the value of livings is ascertained in case of pluralities. In like manner, and upon the same principle, surveys of the possessions of religious houses, previous to the dissolution of monasteries, are received in evidence, Kellington, vicar, v. Trinity Coll. Camb.; 1 Wils. 170; and these surveys are held admissible, although the commissions under which they were taken are not now to be found. See 1 Wils. 170; 2 Gwill. 542.

TAXES. A tax in England differs from what is commonly called a subsidy, in this, that it is always certain as it is set down in the exchequer book, and levied in general of every town, and not particularly of every man, &c. See Rastall's *Abridgment*, title *Taxes*. A tax may now be defined to be a general aid, subsidy, or supply, granted by the commons in parliament assembled, and confirmed by act of parliament; constituting the king's extraordinary revenue, and paid yearly towards the expenses of government. 1 Comm. c. 8.

Under title King V. 4 the taxes are stated, from Blackstone, as part of the king's extraordinary revenue, as applicable to the purposes of government: they may, however, more properly be considered as the national revenue applicable to public purposes. For their nature and account see GREAT BRITAIN.

TAXILA, in ancient geography, an extensive country of India, between the Indus and the Hydaspes.

TAXILES, or **TAXILUS**, a king of Taxila, called also Omphis in the age of Alexander. He submitted to the conqueror, who rewarded him liberally. See MACEDON.

TAXIMAQUILUS, a king in the south part of Britain, contemporary with Julius Cæsar. Cæs. de Bel. Gal. c. 22.

TAXIS, in ancient architecture, the ordonnance; the disposition. Ash.

TAXUS, the yew tree, in botany, a genus of plants belonging to the class of diœcia, and order of monodelphia; and in the natural system ranging under the fifty-first order, *conifere*. The male calyx is triphyllous, gemmaceous, and imbricated: there is no corolla; the stamina are numerous; the antheræ peltated and octofid. The female calyx resembles the male; there is no corolla nor style, and only one seed with a calycle resembling a berry very entire. There are five species:—1. *T. baccata*, the common yew tree, is a native of Britain, France, Switzerland, &c., and of North America. It is distinguished from the other species by linear leaves which grow very close, and by the receptacles of the male flowers being subglobose. The wood is reddish, full of veins, and flexible, very hard and smooth, and almost incorruptible. Its hardness renders it very proper for turners and cabinet makers. It produces berries which are red, mucilaginous, and have a sweet mawkish taste. They are often eaten by birds, and are therefore not poisonous: but it is a common opinion that the leaves are poisonous to cattle, and many facts

are mentioned of horses and cows having died by eating them. But others deny this. 2. *T. Capensis*, a native of the Cape of Good Hope, is mentioned by Mr. Sonnerat. 3. *T. macrophylla* is described by Sir Charles Thunberg, in his *Flora Japonica*, as a native of Japan. 4. *T. nucifera*, the nut bearing yew, is the only other species mentioned by Linnaeus.

5. *T. verticillata*, another species growing in Japan, is described by Sir Charles Thunberg.

TAY, called by the Romans *Tavus* or *Taus*, a river in Scotland; which is said to contribute a greater quantity of water to the ocean than any river in Great Britain. It rises in Breadalbane, on the frontiers of Lorn; and, having augmented its stream by several small rills, spreads itself into a lake called *Loch Dochart*; out of which having run but a little space, it expands again. Leaving this second lake, it rolls some miles with a considerable body of water, and then diffuses itself into the spacious *Loch Tay*, which is sixteen miles long. Almost as soon as it issues from this lake, which it does under a handsome bridge, it receives the river *Lyon*; and, pursuing a course due east, it receives ten miles farther on the *Tummel*, which conveys the united rivulets of *Athol* into its channel. Bending them to the south for six miles, it reaches *Dunkeld*; where an elegant bridge was built in 1806. Declining still to the south-east with a winding course, for above twelve miles, the Tay receives the *Isla*, and a large supply of waters from the county of *Angus*; and, then running south-west for eight miles more, is joined in that space by several rivers, the most considerable of which is the *Almond*. Turning then to the south-east, this copious river rolls past *Perth*, the capital of the county. The Tay, continuing still a south-east course, receives a few miles below *Perth* the river *Earne*. Swelled by the waters of this last river, the Tay, running next directly east, enlarges itself till it becomes about three miles broad; but contracts again before the town of *Dundee*; soon after which it opens into the German Ocean. At the entrance of the frith there are sands both on the north and south side: the former styled *Goa*, the latter *Aberlay* and *Drumlan*: and before these, in the very mouth of the frith, those which are called the *Cross Sands*. At *Buttonness*, which is the northern promontory, there are two light houses. The space between the north and the south sands may be nearly a mile, with about three fathoms water; but, being within the frith, it grows deeper, and in the road of *Dundee* is full six fathoms. The frith of Tay is not indeed so large or so commodious as that of *Forth*, but from *Buttonness* to *Perth* it is not less than forty miles; and the whole may be without any great impropriety styled a harbour, which has *Fife* on one side, and the shires of *Perth* and *Angus* on the other.

TAY, a river of Ireland, in *Waterford*, which runs into the sea; seven miles W. N. W. of *Dun-carvon Bay*.

TAY, FRITH OF, an arm of the sea, at the mouth of the Tay, which divides the county of *Fife* from those of *Perth* and *Forfar*.

TAY, LOCH, a lake of *Perthshire*, through

which the river Tay runs, sixteen miles long, and in many parts above one broad. The banks of this lake are finely shaded with trees; and it has an island, on which are the ruins of a priory built by Alexander I.

TAYGETA, or TAYGETE, in the mythology, a daughter of *Atlas* and *Pleione*, and mother of *Lacedæmon* by *Jupiter*. She became one of the *Pleiades*.

TAYGETUS, a mountain of *Laconia*, west of the *Eurotas*. It hung over *Lacedæmon*, and a part of it once fell down and destroyed the suburbs. The *Spartan* women celebrated the *Bacchanalia* upon it.

TAYLOR (Dr. *Jeremy*), was the son of a barber at *Cambridge*, where he was educated. He became divinity lecturer of *St. Paul's* in *London*; and was, by the interest of archbishop *Laud*, elected fellow of *All Soul's College*, *Cambridge*, in 1636. In 1638 he became chaplain to the archbishop, who made him rector of *Uppingham* in *Rutlandshire*. In 1642 he was chaplain to the king; and a frequent preacher before him at *Oxford*. He afterwards attended his army as chaplain. Upon the declining of his cause, he retired into *Wales*, where he officiated as minister, and kept a school. Having spent several years there, he lost three sons of great hopes in three months. This made him leave the country, and go to *London*, where he officiated in a private congregation of loyalists. At length *Edward lord Conway* carried him over into *Ireland*, and settled him at *Portmore*. Upon the Restoration he returned to *England*; soon after he was advanced to the bishopric of *Down* and *Connor* in *Ireland*. He was likewise made a privy-counsellor and vice-chancellor of the university of *Dublin*; which he held till his death. He died of a fever at *Lisnegarvy* in 1667. He was the author of several works on divinity.

TAYLOR (Dr. *Brook*) was born at *Edmonton*, *August 18th, 1685*. He was the son of *John Taylor, esq.*, of *Bifron's House* in *Kent*, by *Olivia*, daughter of *Sir Nicholas Tempest*, of *Durham, bart.* His grandfather, *Nathaniel Taylor*, was one of those puritans whom 'Cromwell appointed by letter, *June 14th, 1653*, to represent *Bedford* in parliament.' In 1701 he was entered a Fellow Commoner of *St. John's College, Cambridge*. In 1708 he wrote his treatise *On the Centre of Oscillation*, in the *Philosophical Transactions*. In 1709 he took his degree of *A. B.* In 1712 he was chosen *F. R. S.* In 1712 he presented to the *Royal Society* three papers:—1. *On the Ascent of Water between two Glass Planes*; 2. *On the Centre of Oscillation*; and, 3. *On the Motion of a Stretched String*. In 1713 he presented a paper on *Music*. In 1714 he was elected secretary: same year he took at *Cambridge* his degree of *LL. D.*, and sent to *Sir Hans Sloane*, *An Account of some Curious Experiments relative to Magnetism*; which was printed in the *Transactions*. In 1715 he published in *Latin* his *Methodus Incrementorum*; also a curious essay, preserved in the *Philosophical Transactions*, entitled *An Account of an Experiment for the Discovery of the Laws of Magnetic Attraction*; likewise a treatise *On*

the Principles of Linear Perspective. In the same year he conducted a controversial correspondence with the count Raymond de Montmort, on the Tenets of Malebranche; which occasioned his being particularly noticed in the eulogium pronounced by the French academy, on that eminent metaphysician. The new philosophy of Newton engaged the attention of mathematicians and philosophers both at home and abroad. In 1716 he went to Paris, where his society was very much courted. In 1717 he returned to London, and wrote three treatises, which were published in the Philosophical Transactions, vol. xxx. His intense application having impaired his health, he went to Aix-la-Chapelle, and resigned his secretaryship in 1718. After his return, in 1719, he applied to subjects of a very different kind, such as A Treatise on the Jewish Sacrifices, and a Dissertation on the Lawfulness of Eating Blood. He also revised his treatise on Linear Perspective. Drawing continued also to be his favorite amusement to his last hour. In 1721 he published his last paper in the Philosophical Transactions, entitled An Experiment to ascertain the Proportion of Expansion of Liquor in the Thermometer, with regard to the degree of Heat. In 1721 he also married Miss Bridges of Wallington in Surrey. She died in 1725, and he united himself to Miss Sawbridge of Olantigh, in Kent. In 1729, on the death of his father, he succeeded to the family estate of Bifrons. In 1730 he lost his wife in child bed. In the interval between 1721 and 1730 he wrote a Treatise of Logarithms. The essay entitled *Contemplatio Philosophica*, published by Sir William Young in 1793, appears to have been written about this time. Having survived his second wife little more than a year, Dr. Brook Taylor died of a decline, aged forty, December 29th, 1731. He was a finished Christian, gentleman, and scholar.

TAYLOR (Dr. John), a learned dissenting minister, born in Lancashire. He settled first at Kirkstead in Lincolnshire, where he preached to a small congregation, and taught a grammar-school for nearly twenty years. Afterwards he removed to Norwich, where he preached many years, until he went to superintend the academy at Warrington, in Lancashire. He died in 1761; and, among several other performances, was the author of a Hebrew and English Concordance, 2 vols. folio.

TAYLOR (Jane), an accomplished female writer, born September 23d, 1783, in London, where her father, a respectable artist, then resided. Being also a dissenting minister, Mr. Taylor accepted, in 1792, an invitation from a congregation at Colchester to officiate as their pastor, and carried his daughters thither with him, continuing to superintend their education, and teaching them his own art as an engraver. It was in the intervals between these pursuits that Miss Taylor began to commit the effusions of her genius to writing; and, a visit to London in 1802 introducing her to the society of some young females of congenial disposition and talent, she, as well as her sister, was induced to join them in contributing to the Minor's Pocket Book, a small publication, in which her first work, the Beggar

Boy, appeared in 1804. The success of this little poem encouraged her to proceed, and from this period till 1813 she continued to publish occasionally miscellaneous pieces in verse, of which the principal are entitled *Original Poems for Infant Minds*, in 2 vols.; *Rhymes for the Nursery*, in 1 vol.; and some verses in *The Associate Minstrels*, a publication written in conjunction with the ladies already alluded to, and Mr. Josiah Conder. In the winter of the last mentioned year she commenced a prose composition of higher pretension, which appeared in 1815 under the name of *Display*, and met with much success. Her last and principal work consists of *Essays in Rhyme on Morals and Manners*. The latter part of her life was passed in occasional excursions from Ongar, in which place her family had resided since the year 1810. After some months of lingering debility, in which however the vigor of her mind appears to have remained to the last, this amiable and intellectual female expired of a pulmonary complaint in the month of April 1823.

TAYLOR BRD. See MOTACILLA.

TAYRA, in zoology. See MUSTELA.

TCHANG TE, a city of China, of the first rank, in Ho-nan, the most northern in the province. A fish resembling a crocodile is said to be known here, the fat of which, when kindled, cannot be put out. It has also a mountain so steep and inaccessible that in time of war the citizens retire to it, and bid defiance to their foes. It comprehends one city of the second class, and six of the third in its district; and is 255 miles S. S. W. of Peking. Long. 131° 44' E. Ferro, lat. 36° 6' N.

TCHANG-TCHIA, a city of China of the first rank, on the Heng River, in Hou-quang. A great festival is celebrated here in the fifth month throughout the empire. The mandarin who governed this city, being much esteemed and beloved by the people for his probity, happening to be drowned in the river, they instituted this festival to his honor. It includes certain fights upon the water, as if they intended to search for the mandarin. The festival was at first peculiar to this city, but came afterwards to be observed throughout the empire. 742 miles S. of Peking.

TCHANG-TCHIEOU, a city of China of the first rank, in Fo-kien, the most southerly in the province. It stands on a river, and carries on a considerable trade. The neighbouring mountains abound with the finest crystal. 950 miles south of Peking.

TCHANG-TCHEOU, a city of China of the first rank, in Kiang-nan. It is two leagues in circumference, situated on the great canal, and has a very extensive trade. The population has been estimated at 200,000 souls. 525 miles S. S. E. of Peking.

TCHANG-TE, a city of the first rank in China, in Hou-quang. It stands on a river near the great lake Tong-tung. 717 miles S. S. W. of Peking.

TCHAOU-KING, a city of China of the first rank, in Quang-tong. It is reckoned the best built city in the province, and is the residence of the tsong-tsi, or governor. The port is very spacious, placed at the confluence of three rivers, one of which communicates with Canton. 1062 miles S. S. W. of Peking.

TCHE-KIANG, a province of China, bounded on the north and north-west by Kiang-nan, on the east by the sea, on the south by Fo-kien, and on the south-west by Kiangsee; about 200 miles in length from north to south, and from 120 to 180 broad. This was formerly the residence of some of the emperors, and is one of the most considerable provinces in the empire, on account of its maritime situation. The air is pure and healthful, the plains watered by a number of rivers and canals, and it abounds with springs and lakes. The natives are mild and polite to strangers, but extremely superstitious. A prodigious quantity of silk-worms are bred in this province. The principal branch of trade, therefore, consists in silk stuffs, an immense quantity of which is sent to every part of China, Japan, the Philippines, and Europe. A complete suit of silk may be bought here as cheap, we are told, as one of the coarsest woollen cloth in France. Excellent hams are also brought from this province; and the tallow-tree grows here. In Tche-kiang there are reckoned to be eleven cities of the first class, seventy-two of the third, and eighteen fortresses, which in Europe would be accounted large cities. According to Sir George Staunton the number of inhabitants is 21,000,000.

TCHEOU-CHEN, an island of China, sixty miles from Ning-po, where the British embassy first landed.

TCHEOU-KONG, a celebrated Chinese astronomer, who flourished above 1000 years before the Christian era, and is said to have invented the mariner's compass. He erected a tower in the city of Ho-nan, for an observatory; and there is still to be seen in it an instrument which he made and used for finding the shadow at noon, and determining the latitude.

TCHING-KIANG, a city of China of the first rank, in Kiang-nan, on the south side of the Yang-tse. This city is not above a league in circumference; but it is one of the most considerable for its situation and commerce, and the key of the empire towards the sea. The walls are above thirty feet in height in several places, and the streets and suburbs are paved with marble. 470 miles S. S. E. of Peking.

TCHING-TCHEOU, a city of China of the first rank, in Hou-quang. It is situated on an angle made by two rivers, and the country is watered by a great number of brooks, and yields plenty of quicksilver, lapis lazuli, and green stones for painting. There are also mines of silver and gold. The district of this city contains one of the second order, and nine of the third. 65 miles S. S. W. of Peking.

TCHING-TEOU, a town of Corea, thirty miles S. S. W. of Kang-tcheou.

TCHING-TING, a large city of China of the first rank, in Pe-che-lee. It is about four miles in circumference, and its jurisdiction is very extensive, and comprehends thirty-two towns, five of which are of the second, and twenty-seven of the third class.

TCHING-TOU, a city of China of the first rank, in Se-chuen. This was formerly the residence of the emperors, and one of the largest and most beautiful in China; but in 1646 it was al-

most entirely destroyed by the Tartars. Its temples, bridges, and the ruins of ancient palaces, are still, however, objects of great admiration. 810 miles south-west of Peking.

TCHONG-KING, a very flourishing city of China of the first rank, in Se-chuen. It is indebted for its trade to its situation at the confluence of two remarkable rivers; one of which, called Kin-cha-kiang, or Golden-sand, receives in its course all the streams from the mountains which rise in the neighbouring confines of Tartary. The other is Ta-kiang, which has its source beyond the boundaries of China, and is called also Yang-tse-kiang. Tchong-king is built upon a mountain, and rises in the form of an amphitheatre. The air is wholesome and temperate; and the city is celebrated for its fish, and a particular kind of trunks made with canes, interwoven like basket work. It has in its district three cities of the second class, and eleven of the third. It is 150 miles west of Peking.

TCI-NAN, or TSI-NAN, a populous city of China of the first rank, in Shan-tung, situated south of the river Tsing-ho, or Tsi. This city is much respected by the Chinese on account of its having been formerly the residence of a long series of kings, whose tombs, rising on the neighbouring mountains, crown a delightful prospect. It is 235 miles south of Peking.

TEA, *n. s.* French *thé*; Chinese *theh*. A well-known Chinese plant. See below.

The muses' friend, *tea*, does our fancy aid,
Repress those vapours which the head invade.

Waller.

One has a design of keeping an open *tea* table.

Addison.

He swept down a dozen *tea* dishes. *Spectator.*

Green leaves of *tea* contain a narcotick juice, which exudes by roasting; this is performed with great care before it is exposed to sale.

Arbutnot on Aliments.

A living *tea* pot stands, one arm held out,
One bent; the handle this, and that the spout.

Pope.

The mistress of the *tea* shop may give half an ounce.

Swift.

When you sweep, never stay to pick up *tea* spoons.

Id.

TEA. The tea plant, which is an evergreen, grows to the height of five or six feet: Le Comte says ten or twelve. The leaves, which are the only valuable part of it, are about an inch and a half long, narrow, indented, and tapering to a point like those of the sweet briar, and of a dark green color. The root is like that of the peach tree, and its flowers resemble those of the white wild rose. The stem spreads into many irregular branches. The wood is hard, of a whitish green color, and the bark is of a greenish color, with a bitter, nauseous, and astringent taste. The fruit is small, and contains several round blackish seeds, about the bigness of a bean or large pea.

The tea plant delights in valleys, is frequent on the sloping sides of mountains and the banks of rivers, where it enjoys a southern exposure. It flourishes in the north latitudes of Peking, as well as round Canton, but attains the greatest perfection in the mild temperate regions of Nankin. It is said only to be found between 30° and 45° lat. N. In Japan it is planted round the

borders of fields, without regard to the soil ; but, as it is an important article of commerce with the Chinese, whole fields are covered with it, and it is by them cultivated with care. It is propagated by seeds ; from six to twelve are put into a hole about five inches deep, at certain distances from each other. The reason why so many seeds are sown in the same hole is said to be, that only a fifth part vegetate. Being thus sown they grow without any other care.

The leaves are not fit for being plucked till the shrub be of three years' growth. In seven years it rises to a man's height ; but, as it then bears but few leaves, it is cut down to the stem, and this produces a new crop of fresh shoots the following summer, every one of which bears nearly as many leaves as a whole shrub. Sometimes the plants are not cut down till they are ten years old. We are informed by Kœmpfer that there are three seasons in which the leaves are collected in the isles of Japan, from which the leaves derive different degrees of perfection. The first gathering commences at the end of February or beginning of March. The tea is then small, tender, and unfolded, and not above three or four days old : these are called *ficki tsiaa*, or tea in powder, because it is pulverised ; it is also called imperial tea, being generally reserved for the court and people of rank ; and sometimes also it is named bloom tea. It is sold in China for 1s. 8d. or 2s. per pound. The laborers employed in collecting it do not pull the leaves by handfuls, but pluck them one by one, and take every precaution that they should not break them. However long and tedious this labor may appear, they gather from four to ten or fifteen pounds a day. The second crop is gathered about the end of March or beginning of April. At this season part of their leaves have attained their full growth, and the rest are not above half their size. This difference does not, however, prevent them from being all gathered indiscriminately. They are afterwards picked and assorted into different parcels, according to their age and size. The youngest, which are carefully separated from the rest, are often sold for leaves of the first crop, or for imperial tea. Tea gathered at this season is called *too-tsiaa*, or Chinese tea, because the people of Japan infuse it and drink it after the Chinese manner. The third crop is gathered in the end of May or in June. The leaves are then very numerous and thick, and have acquired their full growth. This kind of tea, which is called *Ben-tsiaa*, is the coarsest of all. Some of the Japanese collect their tea only at two seasons of the year, which correspond to those already mentioned ; others confine themselves to one general gathering of their crop in June ; but they always form afterwards different assortments of their leaves. The finest and most celebrated tea of Japan is that which grows near *Ud-si*, a village near *Meaco* on the coast. In the district of this village is a delightful mountain of the same name, the climate of which is said to be extremely favorable to the culture of tea ; it is therefore enclosed by a hedge, and surrounded with wide ditches, which prevent all access to it. The tea shrubs that grow on this mountain are planted in regular order, and are divided by

avenues and alleys. The care of this place is entrusted to people who guard the leaves from dust and defend them from the inclemency of the weather. The laborers who are appointed to collect the tea abstain from every kind of gross food for some weeks before they begin, that their breath and perspiration may not in the least injure the leaves. They gather them with the most scrupulous nicety, and never touch them but with very fine gloves. When this choice tea has undergone the process necessary for its preparation, it is escorted by the superintendent of the mountain and a strong guard to the emperor's court, and reserved for the use of the imperial family.

When the tea leaves have been collected, they are exposed to the steam of boiling water ; after which they are put upon plates of copper, and held over the fire until they become dry and shrivelled, and appear such as we have them in Europe. Kœmpfer says, tea is prepared in the same manner in the isles of Japan. The people of Japan and China generally keep their tea a year before using it, because, when fresh and newly gathered, it possesses a narcotic quality which hurts the brain. Imperial tea is generally preserved in porcelain vases, or in leaden or tin canisters covered with fine mats made of bamboo. Common tea is kept in narrow-mouthed earthen pots ; and coarse tea, the flavor of which is not so easily injured, is packed up in baskets of straw.

The Chinese pour boiling water over their tea, and leave it to infuse, as we do in Europe ; but they drink it without any mixture, and even without sugar. The people of Japan reduce theirs to a fine powder, which they dilute with warm water until it has acquired the consistence of thin soup.

Tea was introduced into Europe in 1610 by the Dutch East India Company. It is generally said that it was first imported from Holland to England in 1666 by the lords Arlington and Ossory, who brought it into fashion among people of quality. But it was used in Coffee-houses before this period, as appears from an act of parliament made in 1660 ; in which a duty of 8d. was laid on every gallon of the infusion sold in these places. In 1665 it was sold in London for 60s. per pound, though it did not cost more than 2s. 6d. or 3s. 6d. at Batavia. It continued at this price till 1707. In 1715 green tea began to be used ; and, as great quantities were then imported, the price was lessened, and the practice of drinking tea descended to the lower ranks. In 1720 the French began to send it to us by a clandestine commerce. Since that period the demand has been increasing yearly, and it has become almost a necessary of life in several parts of Europe, and among the lowest as well as the highest ranks.

Many attempts have been made to introduce this valuable plant into Europe ; but, from want of proper precautions, most of these attempts have miscarried. The seeds, being of an oily nature, are apt to grow rancid during a long voyage, unless proper care is taken to preserve them. The finest tea-plant known in England was raised in Kew gardens ; but the first that ever

flourished in Europe was one belonging to the duke of Northumberland at Sion. The plants which are cultivated in the gardens near London thrive well in the green-house during winter, and some stand that season in the open air. Linnæus, who obtained this shrub in its growing state, contrived to preserve it in the open air in the northern latitude of Sweden. France has also procured some plants. There can be no doubt but they would succeed in many countries of Europe, if proper care were paid to their cultivation till they became inured to the climate.

In this country, teas are generally divided into three kinds of green, and five of bohea: the former are, 1. Imperial or bloom tea, with a large loose leaf, light green color, and a faint delicate smell. 2. Hyson, so called from the merchant who first imported it; the leaves of which are closely curled and small, of a green color, verging to a blue: And 3. Singlo tea, from the name of the place where it is cultivated. The boheas are, 1. Souchong, which imparts a yellow green color by infusion. 2. Camho, so called from the place where it is made: a fragrant tea, with a violet smell; its infusion pale. 3. Congo, which has a larger leaf than the following, and its infusion somewhat deeper, resembling common bohea in the color of the leaf. 4. Pekoe tea is known by the appearance of small white flowers mixed with it. 5. Common bohea, whose leaves are of one color. There are other varieties, particularly a kind of green tea, done up in roundish balls, called gunpowder tea.

Dr. Lettsom thinks it most probable that there is only one species of tea, and that the difference between the green and bohea teas depends on the nature of the soil, culture, age, and the manner of drying the leaves. He adds that it has even been observed that a green tea tree, planted in the bohea tea country, will produce bohea, and on the contrary; and that on his examining several hundred flowers, brought both from the bohea and green tea countries, their botanical characters have always appeared uniform. We are principally indebted to Kæmpfer, Le Comte, and Du Halde, for an authentic history of the culture of this exotic shrub, and the manner of preparing or curing its leaves.

The particulars of greatest importance that have been recited have lately been judiciously collected, and the subject further illustrated by additional observations of this writer.

The present consumption of tea in this country is immense, both among the rich and poor. Dr. Lettsom tells us that he has been informed, that at least 3,000,000 lbs. are allowed for the annual home consumption, not including the incredible quantity smuggled into the kingdom; and that the East India Company have generally in their warehouses a supply for three years. In the appendix to Sir George Staunton's Account of lord Macartney's Embassy to China, we have also several statements relating to the tea trade. The average of teas exported from China to Europe in foreign ships, for nine years, viz. from March 1772 to 1780, the average of the number of ships being twelve, was 13,198,201 lbs.; in English ships, at the average of nine, 5,639,939 lbs.: the total average of

ships is twenty-one, and of exported tea 18,838,140 lbs. The annual consumption of tea by foreigners in Europe is estimated at 5,500,000 lbs.; and the consumption of Great Britain and her dependencies is at least 13,338,140 lbs., which, at 700,000 lbs. per ship, would employ thirty-eight large ships constantly in the China trade, instead of eighteen ships, as above, most of which were small, one fleet going out when another is coming home. The above is exclusive of private trade teas, brought legally and illegally into Europe. It is said, upon the authority of confidential information, that the English ships have often smuggled from 1000 to 3000 chests of tea each; and also that the foreign captains bring a large quantity of tea, which they either smuggle at sea, or throw into the sea, the punishment being severe. The loss to the public on 1000 chests of hyson tea smuggled is above £20,000.

The properties of tea, medicinally considered, are strangely controverted: the eastern nations are at least as much possessed with an idea of their extraordinary virtues as the Europeans, but it is, perhaps, because imagination bears as great a sway there as here. The reason why the gout and stone are unknown in China is ascribed to the use of this plant.

Tea, on the one hand, has been extolled as the greatest of all medicines: moderately and properly taken, it certainly acts as a gentle astringent and corroborative: it strengthens the stomach and bowels, and is good against nausea, indigestions, and diarrhœas. It acts also as a diuretic and diaphoretic. The immoderate use of it, however, has been very prejudicial to many, who have been thereby thrown into the diabetes. In Europe, also, infusions of tea-leaves have been extravagantly condemned by some, and commended by others. From the contradictory opinions, even of medical writers, on this subject, the natural inference seems to be that they possess neither noxious nor beneficial powers, in any very considerable degree. They seem, when moderately used, to be for the most part innocent; in some cases they seem to be salutary; in some they are apparently prejudicial. They dilute thick juices, and quench thirst more apparently, and pass off by the natural emunctories more freely, than more watery fluids: they refresh the spirits in heaviness and sleepiness, and seem to counteract the operation of inebriating liquors. From their manifest astringency, they have been supposed to strengthen and brace up the solids; but this effect experience does not countenance, as it is in disorders, and in constitutions in which corroborants are more serviceable, that the immoderate use of tea is peculiarly hurtful, in cold indolent habits, cachexies, chlorosis, dropsies, and debilities of the nervous system. Lewis's *Materia Medica*.

Dr. Lettsom has particularly enquired into the medical effects of tea; and, having observed that infusions of bohea and green tea contribute to preserve sweet some small pieces of beef immersed in them, he infers that they possess an antiseptic power, when applied to the dead animal fibre, and, from their striking a purple color

with salt of iron, he deduces their astringent quality.

From other experiments he concludes that the activity of tea chiefly resides in its fragrant and volatile parts; and that if the use of it be beneficial or injurious to any particular constitution, it becomes so principally by means of this odorous fragrant principle. He apprehends that it is the safest course to use the infusion of the more ordinary kinds of this plant, which abound less with this fragrant principle. Or the tea may be boiled a few minutes, in order to dissipate this volatile part, which stands charged as the cause of those nervous affections that are said to be produced, or aggravated, by the use of this liquor. By this process may likewise be extracted more copiously the more fixed, bitter, and stomachic parts of this vegetable. Our author seems to be thoroughly persuaded of the occasionally noxious effects of this volatile principle, in the finer teas especially, and recommends this last mentioned mode of making tea, or the substitution of the extract instead of the leaves; by the use of which the nervous relaxing effects, which follow the drinking of tea in the usual manner, would be in a great measure avoided. This extract has been imported hither from China, in the form of small cakes, not exceeding a quarter of an ounce each in weight, ten grains of which might suffice one person for breakfast; but it might easily be made here by simple decoction and evaporation, by those who experience the noxious qualities of the volatile principles of this plant. It may be farther observed

that the effect of drinking large quantities of any warm aqueous liquor would be to enter speedily into the course of circulation, and pass off as speedily by urine or perspiration, or the increase of some of the secretions.

Its effects on the solid parts of the constitution would be relaxing, and thereby enfeculating. If this warm aqueous fluid were taken in considerable quantities, its effects would be proportionable, and still greater if it were substituted instead of nutriment. The infusion of tea, however, has these two peculiarities. It is not only possessed of a sedative quality, but also of a considerable astringency; by which the relaxing power, ascribed to a mere aqueous fluid, is in some measure corrected on this account. It is, perhaps, less injurious than many other infusions of herbs, which, besides a very slight aromatic flavor, have very little, if any, stypticity, to prevent their relaxing debilitating effects. So far, therefore, tea, if not too fine, if not drank too hot, nor in too great quantities, is perhaps preferable to any other known vegetable infusion. And if we take into consideration, likewise, its known enlivening energy, our attachment to it will appear to be owing to its superiority in taste and effects to most other vegetables. See Dr. Lettsom's Natural History of the Tea Tree, with Observations on the Medical Qualities of Tea, and Effects of Tea Drinking, 4to., 1772.

The following results of experiments on tea, by Mr. Brande, have been published by him in his Journal:—

One hundred parts of Tea.		Soluble in Water.	Soluble in Alcohol.	Precipit. with Jelly.	Inert Residue.
Green Hyson	14s. per lb.	41	44	31	56
Ditto	12s.	34	43	29	57

Ditto	6s.	35	31	23	65

TEA TREE of New Zealand, a species of myrtie, of which an infusion was drunk by Captain Cooke's people in their voyages round the world. Its leaves were finely aromatic, astringent, and had a particular pleasant flavor at the first infusion; but this went off at the next filling up of the tea-pot, and a great degree of bitterness was then extracted; for which reason it was never suffered to be twice infused. In a fine soil in thick forests this tree grows to a considerable size; sometimes thirty or forty feet in height, and one foot in diameter. On a hilly and dry exposure it degenerates into a shrub of five or six inches; but its usual size is about eight or ten feet high, and three inches in diameter. In this case its stem is irregular and unequal, dividing very soon into branches, which rise at acute angles, and only bear leaves and flowers

at top. The flowers are white, and very ornamental to the whole plant. Mr. White, in his Journal of a Voyage to New South Wales, mentions a shrub which he calls a tea-tree, merely from its being used by the convicts as a succedaneum for tea; for he had not seen the flower, nor did he know to what genus it belonged. It is a creeping kind of a vine, running to a great extent along the ground: the stalk slender; the leaf not so large as the common bay leaf; the taste sweet, exactly like the liquorice root of the shops.

TEACH, *v. a. & v. n.* } *Prct. and part. pass.*
 TEACH'ABLE, *adj.* } taught, sometimes
 TEACH'ABLENESS, *n. s.* } taught, which is now
 TEACHER. } obsolete. Saxon *teacan.*
 To instruct; inform: correlative to learn: dictate; impress on the mind; show; tell: to

perform the office of instructor: the adjective and noun substantives corresponding.

Moses wrote this song, and *taught* it.

Deut. xxxi. 22.

The Lord will *teach* us of his ways, and we will walk in his paths.

Isaiah, ii. 3.

All thy children shall be *taught* of the Lord.

Id. liv. 13.

In vain they worship me, *teaching* for doctrines the commandments of men.

Matt. xv. 9.

Huswives are *taached*, instead of a clocke, How winter night passeth by crowing of cocke.

Tusser.

Nature is no sufficient *teacher* what we should do that may attain unto life everlasting.

Hooker.

I am too sudden bold.

To *teach* a *teacher* ill besecmeth me.

Shakspeare.

I have laboured,

And with no little study, that my *teaching*,

And the strong course of my authority,

Might go one way.

Id.

For the choice of a governor more sufficient, the *teachers* in all the churches assembled themselves.

Raleigh.

Our lecture men, and some others, whom precise people stile powerful *teachers*, do seldom honour it.

White.

'Tis sufficient that matters of faith and religion be propounded in such a way as to render them highly credible, so as an honest and *teachable* man may willingly and safely assent to them, and according to the rules of prudence be justified in so doing.

Wilkins.

Teach us by what means to shun

The 'inclement seasons.

Milton.

Wolves shall succeed for *teachers*.

Id.

I went into the temple, there to hear

The *teachers* of our law, and to propose

What might improve my knowledge or their own.

Id.

How hast thou satisfied me, *taught* to live.

Id.

These were notions born with us; such as we were taught without the help of a *teacher*.

South's Sermons.

If some men *teach* wicked things, it must be that others should practise them.

Id.

Dissenting *teachers* are under no incapacity of accepting civil and military employments.

Swift.

We ought to bring our minds free, unbiassed, and *teachable*, to learn our religion from the word of God.

Watts.

And O! that, humble as my lot,

And scorned as is my strain,

These truths, though known, too much forgot,

I may not *teach* in vain.

Cowper.

TEAD, or TEDE, *n. s.* Lat. *tæda*. A torch; a flambeau. Not in use.

A bushy *tead* a groom did light,

And sacred lamp in secret chamber hide.

Spenser.

Hymen is awake,

And long since ready from his mask to move,

With his bright *tead* that flames with many a flake.

Id.

TEAGUE, a name of contempt used for an Irishman.

TEAK WOOD. See TECTONA.

TEAL, *n. s.* Belg. *teelingh*. A wild fowl.

Some serve for food to us, and some but to feed themselves; amongst the first sort we reckon the dipchick, coots, *teal*, wigeon.

Carew's Survey of Cornwall.

TEAM, *n. s.* Sax. *týme*, a yoke; Lat. *temo*,

the team of a carriage. A number of horses or oxen drawing at once the same carriage.

Thee a ploughman all unweeting found,
As he his toilsome *team* that way did guide,
And brought thee up in ploughman's state to bide.

Spenser.

I am in love; but a *team* of horses shall not pluck that from me, nor who 'tis I love.

Shakspeare.

Making such difference betwixt wake and sleep,

As is the difference betwixt day and night,

The hour before the heavenly harnessed *team*

Begins his golden progress in the east.

Id. Henry IV.

After the declining sun

Had changed the shadows, and their task was done,
Home with their weary *team* they took their way.

Roscommon.

He heaved with more than human force to move
A weighty stone, the labour of a *team*.

Dryden.

Like a long *team* of snowy swans on high,

Which clap their wings and cleave the liquid sky.

Id.

In stiff clays they may plow one acre of wheat with a *team* of horse.

Mortimer's Husbandry.

TEANUM, two ancient towns of Italy, 1. In Campania, on the Appian road, on the east bank of the Liris, called also Sidicinium, to distinguish it from 2. Another town in the west of Apulia, on the coast of the Adriatic.—Cic. Cluent 9, 69. Plin. 31 c. 2.

TEAR, *v. a. & v. n.* *Pret.* tore, anciently tare; *part. pass.* torn. Sax. *tæpan*; Swed. *tara*. To pull in pieces; lacerate; rend; separate by violent pulling; break; shatter; pull or drive violently: to fume; rave with passion: bluster.

The one went out from me; and I said, Surely he is *torn* in pieces, and saw I him not since.

Gen. xlv. 28.

Neither shall men *tear* themselves for them in mourning, to comfort them for the dead.

Jer. xvi. 7.

Come, feeling night!

And with thy bloody and invisible hand

Cancel and *tear* to pieces that great bond

Which keeps me pale.

Shakspeare. Macbeth.

Old men with dust deformed their hoary hair

The women beat their breasts, their cheeks they *tare*.

Shakspeare.

In the midst a *tearing* groan did break

The name of Antony.

Id. Antony and Cleopatra.

Solyman

Rhodes and Buda from the Christians *tore*.

Waller.

As storms the skies, and torrents *tear* the ground,

Thus raged the prince, and scattered death around.

Dryden.

He roared, he beat his breast, he *tore* his hair.

Id.

All men transported into outrages for small trivial matters, fall under the inuendo of this bull, that ran *tearing* mad for the pinching of a mouse.

L'Estrange.

Is it not as much reason to say that God destroys fatherly authority, when he suffers one in possession of it to have his government *torn* in pieces, and shared by his subjects?

Locke.

The hand of fate

Has *torn* thee from me, and I must forget thee.

Addison.

Blush rather that you are a slave to passion,
Which, like a whirlwind, *tears* up all your virtues,
And gives you not the leisure to consider.

A. Philips.

John *tore* off lord Strutt's servants' clothes: now and then they came home naked.

Arbuthnot's History of John Bull.

Ambassadors sent from Carthage were like to be
turn to pieces by the populace. *Arbutnot.*

TEAR, *n. s., v. a., & v. n.* } Saxon, *teap*;
 TEAR-FALLING, *adj.* } Dan. *taare*. The
 TEAR-FUL } water which

strong passion or emotion forces from the eyes ;
 any moisture trickling in drops: the adjectives
 correspond.

I am in

So far in blood, that sin will pluck on sin :
Tearfalling pity dwells not in this eye. *Shakspeare.*

She comes, and I'll prepare

My *tear*-stained eyes to see her miseries. *Id.*

The pretty vaulting sea refused to drown me,
 Knowing that thou wouldst have me drowned on
 shore

With *tears* as salt as sea, through thy unkindness. *Id.*

Is't meet that he

Should leave the helm, and, like a fearful lad,
 With *tearful* eyes add water to the sea ? *Id.*

Cromwell, I did not think to shed a *tear*

In all my miseries ; but thou hast forced me.

Let's dry our eyes. *Id. Henry VIII.*

Tears are the effects of compression of the moisture
 of the brain upon dilatation of the spirits.

Bacon's Natural History.

She silently a gentle *tear* let fall. *Milton.*

Let Araby extol her happy coast,
 Her fragrant flowers, her trees with precious *tears*,
 Her second harvests. *Dryden.*

This clears the cloudy front of wrinkled care,
 And dries the *tearful* sluices of despair :
 Charmed with that virtuous draught, the exalted
 mind

All sense of woe delivers to the wind. *Pope's Odyssey.*

The losses, the crosses,

That active man engage !

The fears all, the *tears* all,

Of diin declining age ! *Burns.*

He dared not raise to his that deep blue eye,
 Which downcast drooped in *tearless* agony. *Byron.*

TEARS. For an accurate analysis of this
 fluid we are indebted to Messrs. Fourcroy and
 Vauquelin. It is transparent and colorless like
 water; has scarcely any smell, but its taste is
 always perceptibly salt. Its specific gravity is
 somewhat greater than that of distilled water.
 It gives to paper stained with the juice of the
 petals of mallows or violets a permanently green
 color, and therefore contains a fixed alkali. It
 unites with water, whether cold or hot, in all
 proportions. Alkalies unite with it readily, and
 render it more fluid. The mineral acids produce
 no apparent change upon it. Exposed to the
 air, this liquid gradually evaporates and becomes
 thicker. When nearly reduced to a state of
 dryness, a number of cubic crystals form in the
 midst of a kind of mucilage. These crystals
 possess the properties of muriate of soda; but
 they tinge vegetable blues green, and therefore
 contain an excess of soda. The mucilaginous
 matter acquires a yellowish color as it dries.

Tears are composed of the following ingredi-
 ents:—1. Water; 2. Mucus; 3. Muriate of
 soda; 4. Soda; 5. Phosphate of lime; 6. Phos-
 phate of soda. The saline parts amount only
 to about 0.01 of the whole, or probably not so
 much.

TEARUS, a river of ancient Thrace, rising in
 Vol. XXI

the same rock from thirty-eight different sources,
 some of which were hot, and others cold. Darius
 raised a column on its banks when he marched
 against the Scythians.—*Plin. iv. c. 11.*

TEARY, or TEHREE, a town of Hindostan,
 province of Allahabad, capital of a chief under
 the British protection, whose territories are situ-
 ated on the north-west boundary of Bundelcund.
 Although compelled to pay tribute for a long
 period to the Mahrattas, he was never dispossessed
 of his lands, and during the war, in 1809, the
 rajah requested to be enrolled among the num-
 ber of the British allies, and was of considerable
 utility. His revenue is estimated at about
 £50,000 per annum.

TEASE, *v. a.* } Sax. *teapan*. To comb or
 TEASER, *n. s.* } unravel wool or flax: scratch
 cloth in order to level the nap: hence torment or
 vex impertinently: the noun substantive cor-
 responding.

Not by the force of carnal reasons,
 But indefatigable *teasing*. *Hudibras.*

My friends always *tease* me about him, because he
 has no estate. *Spectator.*

After having been present in public debates he was
teased by his mother to inform her of what had passed. *Addison.*

We system-makers can sustain
 The thesis, which you grant was plain ;
 And with remarks and comments *tease* ye,
 In case the thing before was easy. *Prior.*

A fly buzzing at his ear makes him deaf to the best
 advice. If you would have him come to himself,
 you must take off his little *teaser*, which holds his
 reason at bay. *Collier.*

Thus always *teasing* others, always *teased*,
 His only pleasure is—to be displeas'd. *Cowper.*

TEA'SEL, *n. s.* Sax. *teapl*. A plant.

The species are three: one is called *carduus fullo-*
num, and is of singular use in raising the nap upon
 woollen cloth. *Miller.*

TEAT, *n. s.* Sax. *teat*; Belg. *tette*; Welsh.
teth. The dug of a beast; anciently the pap of
 a woman.

And in the myddil of seuene golden candlestickis
 oon lyk to the sone of man clothed with a long gar-
 nement, and gird at the *tetis* with a goldun girdil.
Wiclif. Apoc. i.

Even at thy *teat* thou hadst thy tyranny. *Shakspeare.*

Snows cause a fruitful year, watering the earth
 better than rain; for the earth sucks it as out of the
teat. *Bacon.*

When we perceive that bats have *teats*, we infer
 that they suckle their younglings with milk. *Brown's Vulgar Errors.*

It more pleas'd my sense,
 Than smell of sweetest fennel, or the *teats*
 Of ewe or goat dropping with milk at even. *Milton.*

Infants sleep, and are seldom awake but when
 hunger calls for the *teat*. *Locke.*

The goat, how bright amidst her fellow stars,
 Kind Amalthea, reach'd her *teat* distent
 With milk, thy early food. *Prior.*

An' tent them duly, e'en an' morn,
 Wi' *teats* o' hay, an' rips o' corn. *Burns.*

TEATE, TEATEA, or TEGEATE, an ancient
 town of Italy in Latium.—*Sil. Ital. 8 v. 522.*

TEA-TREE, a moveable board, with a raised
 border, generally pierced, made of metal, maho-
 2 Y

gany, or other wood, for holding the tea apparatus.

TECHES, a mountain of Pontus, from the top of which Xenophon and his 10,000 Greeks first saw the sea.—Xenophon 4.

TECHMESSA, the daughter of Teuthras, king of Phrygia, who was carried captive by Ajax, and became mother of his son Erysiaces by him. She afterwards prevented him from killing himself; which forms the subject of a scene in one of Sophocles's tragedies.

TECHNICAL, *adj.* Fr. *technique*; Gr. *τεχνικός*. Belonging to arts; not in common or popular use.

In *technical* words, or terms of art, they refrain not from calling the same substance sometimes the sulphur, and sometimes the mercury of a body. *Locke*.

TECHNICAL expresses somewhat relating to arts and sciences. It is also particularly applied to a kind of verses wherein are contained the rules or precepts of any art, thus digested to help the memory to retain them.

TE'CHY, *adj.* Ital. *testaccio*. Peevish; fretful; irritable; froward. Obsolete.

I cannot come to Cressid but by Pandar,
And he is as *techy* to be wooed to woove,
As she is stubborn-chaste against all sute.

Shakspeare.

When it did taste the wormwood on the nipple,
and felt it bitter, pretty fool, to see it *techy*, and fall out with the dug!

Id. Romeo and Juliet.

TECMON, an ancient town of Epirus. *Livy*.

TECRIT, A town of Irak Arabi, in Mosul, on the western bank of the Tigris. It is thought to be the Birtha or Vitra of the ancients, and was a considerable town in 1393, when it was taken by Timur. It contains now only 500 or 600 houses, with two coffee-houses; but the ruins are extensive. Long. 42° 37' E., lat. 34° 37' N.

TECTAMUS, the son of Dorus, grandson of Helen, and great grandson of Deucalion. He went to Crete at the head of a body of Ætoliars and Pelasgi; was made king of Crete, and married a daughter of king Cretheus, by whom he had a son named Asterius.

TECTONA, in botany, a genus of plants belonging to the class of pentandria and order of monogynia. The stigma is dentate; the fruit a dry spongy plum within an inflated calyx; and the nucleus is trilocular. There is only one species, viz. *T. grandis*, Indian oak, or teak wood, which is a native of India.

TECTOSAGÆ, or **TECTOSAGES**, an ancient nation of Gallia Narbonensis, so named because, sagis tegerentur, they were protected by sorcerers. They were among those Gauls who pillaged Rome under Brennus (see **ROME**), and afterwards attempted to plunder the temple of Apollo at Delphi. On their return home they were attacked by a pestilence; and to stop it were ordered to throw into the river all the plunder. Some of them went into Germany and settled in the Hercynian forest; another colony passed into Asia and conquered Phrygia, Cappadocia, and Paphlagonia. Cæs. de Bel. Gal. vi. 23. *Strabo* 4; *Liv.* 38, c. 16.

TECULET, a town of Africa, in the empire of Morocco, situate near the coast of the Atlantic,

on the edge of a mountain: In 1514 this town was sacked by the Portuguese. It has been since re-peopled: fifteen miles east of Mogodor, and ninety-nine north-west of Morocco.

TED, *v. a.* Sax. *teaban*, to prepare. To lay grass newly mown in rows.

The smell of grain or *tedded* grass, or kine,
Or dairy, each rural sight, each rural sound.

Milton.

Prudent his fallen heaps
Collecting, cherished with the tepid wreaths
Of *tedded* grass, and the sun's mellowing beams,
Rivalled with artful heats.

Phillips.

Hay-makers following the mowers, and casting it abroad they call *tedding*.

Mortimer's Husbandry.

TEDANIUS, a river of Liburnia. *Plin.* 3.

TED'DER, or **TETHER**, *n. s.* Belg. *tudder*; Erse *teigher*. A rope with which a horse is tied in the field: any thing by which one is restrained.

We live joyfully, going abroad with our *tedder*.

Bacon.

We shall have them against the wall; we know the length of their *tedder*; they cannot run far from us.

Child.

TE DEUM, *n. s.* Lat. *te Deum*. An hymn of the church, so called from the two first words of the Latin.

The choir,

With all the choicest musick of the kingdom,
Together sung *Te Deum*. *Shakspeare. Henry VIII.*
Te Deum was sung at Saint Paul's after the victory.

Bacon.

TE DEUM is sung in the Romish church with great pomp and solemnity upon the gaining of a victory or other happy event; and is believed to be the composition of St. Ambrose bishop of Milan.

TE'DIOUS, *adj.*

TE'DIOUSLY, *adv.*

TE'DIOUSNESS, *n. s.*

Fr. *tedieux*; Lat. *tedium*. Wearisome by continuance; troublesome; irksome.

That I be not further *tedious* unto thee, hear us of thy clemency a few words.

Acts xxiv. 4.

They unto whom we shall seem *tedious* are in no-wise injured by us, because it is in their own hands to spare that labour, which they are not willing to endure.

Hooker.

In vain we labour to persuade them that any thing can take away the *tediousness* of prayer, except it be brought to the same measure and force which themselves assign.

Id.

Since brevity's the soul of wit,
And *tediousness* the limbs and outward flourishes,
I will be brief.

Shakspeare. Hamlet.

She distastes them all within a while;
And in the sweetest finds a *tediousness*.

Davies.

More than kisses, letters mingle souls,
For thus friends absent speak: this ease controuls
The *tediousness* of my life.

Donne.

Chief mastery to dissect
With long and *tedious* havock fabled knights.

Milton.

The one intense, the other still remiss,
Cannot well suit with either, but soon prove
Tedious alike.

Id.

Pity only on fresh objects stays,
But with the *tedious* sight of woes decays.

Dryden.

But then the road was smooth and fair to see,
With such insensible declivity,
That what men thought a *tedious* course to run,
Was finished in the hour it first begun.

Harte.

TEDZEN, a considerable river of Korassan, in Persia, the largest, next to the Oxus, in this part of Asia. It is supposed by Mr. Kinneir to rise near Serukhs; and, after a course from east to west, falls into the gulf of Balkan.

TEEM. To pour. A low word imagined by Skinner to come from Dan. *tommen*, to draw out; to pour. The Scots retain it; as, *teem* that water out; hence Swift took this word.

Teem on the remainder of the ale into the tankard, and fill the glass with small beer.

Swift's Directions to the Butler.

TEEM, *v. n.* & *v. a.* } Sax. *team*, offspring.
TEEMLESS, *adj.* } Of being young; be full, or, as it were, pregnant; bring forth; produce: *teemless*, unfruitful.

What's the newest grief?

—Each minute *teems* a new one.

Shakspeare. Macbeth.

Common mother, thou

Whose womb unmeasurable, and infinite breast.

Teems and feeds all. *Id. Timon of Athens.*

The earth obeyed; and strait

Opening her fertile womb, *teemed* at a birth

Innumerable living creatures.

Milton's Paradise Lost.

When the rising spring adorns the mead,

Teeming buds and cheerful greens appear. *Dryden.*

Such wars, such waste, such fiery tracks of dearth,
 Their zeal has left, and such a *teemless* earth. *Id.*

There are fundamental truths, the basis upon which a great many others rest: these are *teeming* truths, rich in store, with which they furnish the mind, and, like the lights of heaven, give light and evidence to other things. *Locke.*

We live in a nation where there is scarce a single head that does not *teem* with politics. *Addison.*

The deluge wrought such a change that the earth did not then *teem* forth its increase, as formerly, of its own accord, but required culture.

Woodward's Natural History.

TEEN, *n. s.* Sax. *teinan*, to kindle; Flem.

teenen is to vex; Sax. *teonan*, injuries. Sorrow; grief. Not in use.

Fry not in heartless grief and doleful *teen*.

Spenser.

My heart bleeds

To think of the *teene* that I have turned you to.

Shakspeare.

TEEMBOO, a city of central Africa, the capital of Foota Jallo, the principal kingdom of the Foulahs. It contains about 7000 inhabitants, who manufacture narrow cloths, iron, silver, wood, and leather. The houses are neatly and conveniently built, at a little distance from each other. 160 miles east of Sierra Leone.

TEES, a considerable river of England, arising in the mountains of Westmoreland, and taking an easterly direction, it divides the North Riding of Yorkshire from the county of Durham in its whole extent. It passes Barnard Castle, Staindrop, Darlington, Yarm, and Stockton, and falls into the German Ocean, in a wide estuary called the Teesmouth, on the south of Hartlepool.

TEESDALE FOREST, a township of England, in Durham, eleven miles north by west of Barnard castle. Population 998.

TEESE, a large unwall'd town of central Africa, in the kingdom of Kasson. The Mandingo inhabitants are remarked by Park for their want of delicacy as to articles of diet, eating

without difficulty rats, moles, and snakes: yet no woman must eat an egg. It is thirty miles north-west of Koonickary.

TEETH, the bones placed in the jaws for chewing food that it may be the more easily digested in the stomach. For the anatomical structure of these see **ANATOMY** and **ZOOLOGY**. The diseases to which they are liable, with the most successful remedies, are fully detailed under **MEDICINE** and **SURGERY**. Quacks and mountebanks use various washes for teeth, the sudden effects of which, in cleaning and whitening the teeth, surprise and please people, but the effects are very pernicious. All the strong acid spirits will do this. One of the best mixtures is the following:—Take plantane-water an ounce, honey of roses two drachms, muriatic acid ten drops; mix the whole, and rub the teeth with a piece of linen rag dipped in this every day till they are whitened. The mouth ought to be well washed with cold water after the use of this or any other acid liquor; and indeed the best of all washes is cold water with or without a little salt; the constant use of this will keep them clean and white, and prevent them from aching.

In early infancy Nature designs us for the softest aliment, so that the gums alone are then sufficient for manducation; but as we advance in life, and require a different food, she wisely provides us with teeth, the hardest and whitest of our bones, and, at full maturity, usually amounting to thirty-two in both jaws; viz. sixteen above, and as many below. Their number varies indeed in different subjects: but it is seldom seen to exceed thirty-two, and it will very rarely be found to be less than twenty-eight.

Each tooth has its *body*, or that part which appears above the gums; and its fangs or root, which is fixed into the socket. The boundary between these two, close to the edge of the gum, where there is usually a small circular depression, is called the neck of the tooth. The teeth of each jaw are commonly divided into three classes; but all are of similar general structure. That is, every tooth is composed of its cortex or enamel, and its internal bony substances. The enamel, or, as it is sometimes called, the vitreous part of the tooth, is a very hard and compact substance, of a white color, and peculiar to the teeth. It is found only upon the body of the tooth, covering the outside of the bony or internal substance. When broken it appears fibrous or striated; and all the striæ are directed from the circumference to the centre of the tooth. This enamel is thickest on the grinding surface, and on the cutting edges or points of the teeth, becoming gradually thinner as it approaches the neck, where it terminates insensibly. Some writers have described it as being vascular, but it is certain that no injection will ever reach this substance; that it receives no tinge from madder; and that it affords no appearance of a circulation of fluids. The bony part of a tooth resembles other bones in its structure, but is much harder than the most compact part of bones in general. It composes the inner part of the body and neck, and the whole of the root of the tooth. This part of a tooth, when completely formed, does not, like the other bones, receive a tinge

from madder, nor do the minutest injections penetrate into its substance, although many writers have asserted the contrary. Mr. Hunter has been therefore induced to deny its being vascular. But we find that a tooth recently drawn, and transplanted into another socket, becomes as firmly fixed after a certain time, and preserves the same color as the rest of the set; whereas a tooth that has been long drawn before it is transplanted will never become fixed. Mr. Hunter, indeed, is aware of this objection, and refers the success of the transplantation, in the first instance, to the living principle possessed by the tooth, and which he thinks may exist independent of a circulation. But, however applicable such a doctrine may be to zoophytes, it is suspected that it will not hold good in man, and others of the more perfect animals: and there does not appear to be any doubt but that, in the case of a transplanted tooth, there is a real union by vessels. 2dly, The swellings of the fangs of a tooth, which in many instances are known to be the effects of disease, and which are analogous to the swelling of other bones, are a clear proof of a similarity of structure, especially as we find them invested with a periosteum. 3dly, It is a curious fact, though as yet perhaps not generally known, that, in cases of phthisis pulmonalis, the teeth become of a milky whiteness, and in some degree transparent. Does not this prove them to have absorbents? Each tooth has an inner cavity, which, commencing by a small opening at the point of the fang, becomes larger, and terminates in the body of the tooth. This cavity is supplied with blood vessels, and nerves, which pass through the small hole in the root. In old people this hole sometimes closes, and the tooth becomes then insensible. The teeth are also invested with periosteum from their fangs to a little beyond their bony sockets, where it is attached to the gums. This membrane seems to be common to the tooth which it encloses, and to the sockets which it lines. The teeth are likewise secured in their sockets by a red substance called the gums, which every where covers the alveolar processes, and has as many perforations as there are teeth. The gums are exceedingly vascular, and have something like cartilaginous hardness and elasticity, but do not seem to have much sensibility. The gums of infants, which perform the offices of teeth, have a hard ridge extending through their whole length; but in old people, who have lost their teeth, this ridge is wanting. The three classes into which the teeth are commonly divided are incisores, canini, and molares, or grinders.

The incisores are the four teeth in the fore-part of each jaw; they derive their name from their use in dividing and cutting the food in the manner of a wedge, and, have each of them two surfaces, which meet in a sharp edge. Of these surfaces, the anterior one is convex, and the posterior one somewhat concave. In the upper jaw they are usually broader and thicker, especially the two middle ones, than those of the under jaw, over which they generally fall by being placed a little obliquely.

The canini, or cuspidati, are the longest of all the teeth, deriving their name from their resemblance

to a dog's tusk. There is one of these teeth on each side of the incisores, so that there are two in each jaw. They are the longest of all the teeth. Their fangs differ from that of the incisores only in being much larger, and their shape may be easily described to be that of an incisor with its edge worn off, so as to end in a narrow point instead of a thin edge. The canini not being calculated for dividing like the incisores, or for grinding, seem to be intended for laying hold of substances. Mr. Hunter remarks, of these teeth, that we may trace in them a similarity of shape, situation, and use, from the most imperfect carnivorous animal, which we believe to be the human species, to the lion, which is the most perfectly carnivorous.

The molares, or grinders, of which there are ten in each jaw, are so called, because from their size and figure they are calculated for grinding the food. The canini and incisores have only one fang, but the three last grinders in the under jaw have constantly two fangs, and the same teeth in the upper jaw three fangs. Sometimes these fangs are divided into two points near their base, and each of these points has, perhaps, been sometimes considered as a distinct fang. The grinders likewise differ from each other in their appearance. The first two on each side, which Mr. Hunter appears to have distinguished very properly by the name of bicuspidæ, seem to be of a middle nature between the incisores and grinders; they have in general only one root, and the body of the tooth terminates in two points, of which the anterior one is the highest, so that the tooth has in some measure the appearance of one of the canini. The two grinders beyond these, on each side, are much larger. Their body forms almost a square with rounded angles; and their grinding surface has commonly five points or protuberances, two of which are on the inner, and three on the outer part of the tooth. The last grinder is shorter and smaller than the rest, and, from its coming through the gums later than the rest, and sometimes not appearing till late in life, is called *dens sapientiæ*. The variation in the number of teeth usually depends on these *dentes sapientiæ*.

The alveolar process, which begins to be formed at a very early period, appears about the fourth month of pregnancy only as a shallow longitudinal groove, divided by slight ridges into a number of intermediate depressions, which are to be the future alveoli or sockets. These depressions are at first filled with small pulpy substances, included in a vascular membrane; and these pulpy substances are the rudiments of the teeth. As these advance in their growth, the alveolar processes become gradually more completely formed. The surface of the pulp first begins to harden, the ossification proceeding from one or more points, according to the kind of tooth that is to be formed. Thus, in the incisores and canini, it begins from one point; in the bicuspidæ from two points, corresponding with the future shape of those teeth; and in the molares from four or five points. As the ossification advances, the whole of the pulp is gradually covered with bone, excepting its under surface, and then the fang begins to be formed.

Soon after the formation of this bony part, the tooth begins to be incrustated with its enamel; but, in what manner this is deposited, we are as yet unable to explain.—Perhaps the vascular membrane, which encloses the pulp, may serve to secrete it. It gradually crystallises upon the surface of the bony part, and continues to increase in thickness, especially at the points and basis of the tooth, till some time before the tooth begins to pass through the gum; and, when this happens, the enamel seems to be as hard as it is afterwards, so that the air does not appear to have the least effect in hardening it, as has been sometimes supposed.—While the enamel is thus forming, the lower part of the pulp is gradually lengthened out and ossified, so as to form the fang. In those teeth which are to have more than one fang, the ossification begins from different parts of the pulp at one and the same time. In this manner are formed the incisores, the canini, and two molares on each side, making in the whole twenty teeth, in both jaws, which are sufficient for the purposes of mastication early in life. As the fangs of the teeth are formed, their upper part is gradually pushed upwards, till at length, about the seventh, eighth, or ninth month after birth, the incisores, which are the first formed, begin to pass through the gum. The first that appears is generally in the lower jaw. The canini and molares, not being formed so soon as the incisores, do not appear till about the twentieth or twenty-fourth month. Sometimes one of the canini, but more frequently one of the molares, appears first.

The danger to which children are exposed during *dentition* arises from the pressure of the teeth in the gum, so as to irritate it, and excite pain and inflammation. The effect of this irritation is that the gum wastes, and becomes gradually thinner at this part, till at length the tooth protrudes. In such cases therefore we may, with great propriety, assist nature by cutting the gum. These twenty teeth are called temporary or milk teeth, because they are all shed between the age of seven and fourteen, and are supplied by others of a firmer texture, with large fangs, which remain till they become affected by disease, or fall out in old age, and are therefore called the permanent or adult teeth. The rudiments of these adult teeth begin to be formed at different periods. The pulp of the first adult incisor, and of the first adult grinder, may be perceived in a fœtus of seven or eight months, and the ossification begins in them about six months after birth. Soon after birth the second incisor, and canine tooth on each side, begin to be formed. About the fifth or sixth year the first bicuspid, and about the seventh the second bicuspid begins to ossify. These bicuspides are destined to replace the temporary grinders. All these permanent teeth are formed in a distinct set of alveoli; so that it is not by the growing of one tooth under another in the same socket, that the uppermost tooth is gradually pushed out, as is commonly imagined; but the temporary teeth, and those which are to succeed them, being placed in separate alveoli, the upper sockets gradually disappear, as the under ones increase in size, till at length the teeth they contain, having

no longer any support, consequently fall out. But, besides these twenty teeth, which succeed the temporary ones, there are twelve others to be added to make up the number thirty-two. These twelve are three grinders on each side in both jaws; and, in order to make room for this addition, we find the jaws grow as the teeth grow, so that they appear as completely filled with twenty teeth as they are afterwards with thirty-two. Hence in children the face is flatter and rounder than in adults. The first adult grinder usually passes through the gum about the twelfth year; the second, which begins to be formed in the sixth or seventh year, cuts the gum about the seventeenth or eighteenth; and the third, or *dens sapientiæ*, which begins to be formed about the twelfth year, passes through the gum between the age of twenty and thirty. The *dentes sapientiæ* have, in some instances, been cut at the age of forty, fifty, sixty, and even eighty years; and it sometimes happens that they do not appear at all. Sometimes likewise it happens that a third set of teeth appear about the age of sixty or seventy. Diemerbroek tells us that he himself, at the age of fifty-six, had a fresh canine tooth in the place of one he had lost several years before; M. du Fay saw two incisores and two canini cut the gum in a man aged eighty-four; Mr. Hunter has seen two fore teeth shoot up in the lower jaw of a very old person; and an account was lately published of a man who had a complete set of teeth at the age of sixty. Other instances of the same kind are to be met with in authors. The circumstance is curious, and from the time of life at which it takes place, and the return of the catamenia, which sometimes happens to women at the same age, it has been very ingeniously supposed, that there is some effort in nature to renew the body at that period.

TEETH of various sorts of machines, as of mill wheels, &c. These are often called cogs by the workmen; and by working in the pinions, rounds, or trundles, the wheels are made to turn one another. Mr. Emerson (in his *Mechanics*, prop. 25) treats of the theory of teeth, and shows that they ought to have the figure of epicycloids for properly working in one another.

TEFF, in botany, a kind of grain sown all over Abyssinia, from which is made the bread commonly used throughout the country. Mr. Bruce says it is herbageous; and that from a number of weak leaves surrounding the root proceeds a stalk of about twenty-eight inches in length, not perfectly straight, smooth, but jointed or knotted at particular distances. This stalk is not much thicker than that of a carnation or july-flower. About five inches from the top a head is formed of a number of smaller branches, upon which it carries the fruit and flowers; the latter of which are small, of a crimson color, and scarcely perceptible by the naked eye but from the opposition of that color. The pistil is divided into two, seemingly attached to the germ of the fruit, and has at each end small capillaments forming a brush. The stamina are three; two on the lower side of the pistil, and one on the upper. These are each of them crowned with two oval stigmata, at first green but after-

wards crimson. The fruit is formed in a capsula, consisting of two conical hollow leaves, which, when closed, seem to compose a small conical pod pointed at the top. The fruit or seed is oblong, and is not so large as the head of the smallest pin; yet it is very prolific, and produces these seeds in such abundance as to yield a very great quantity of meal. Of this tef-bread the natives make a liquor. When well toasted it is broken into small pieces, which are put into a large jar and have warm water poured upon them. It is then set by the fire, and often stirred for several days, the mouth of the jar being closely covered. After being allowed to settle for three or four days it acquires a sourish taste, and is what they call bouza, or the common beer of the country. The bouza in Athara is made in the same manner, only, instead of tef, cakes of barley-meal are employed. Both are very bad liquors, but the worst is that made of barley.

TEFLIS, or TIFLIS, a city of Asia, and capital of the kingdom of Georgia, was visited in 1817 by Sir R. Kerr Porter, who describes it as situated on the sublime banks of the Kur, at the extremity of a defile formed by two bold ranges of mountains.

This city was founded in 1063, by the Tzar Liewwang, who wished to derive personal benefit from certain warm springs in its neighbourhood, and built hovels for the convenience of the occupiers of a small fortress, which stood on an adjacent height. The remains of this ancient bulwark are still to be seen on a hill to the south of the town, at some distance from the station of the modern citadel, of Turkish origin. The position of the old work completely commanded the road along the western bank of the Kur. The streets are, without exception, narrow, and intolerably filthy in wet weather, and dusty in dry; but, since it has come under the dominion of Russia, this inconvenience has been in some degree remedied. The governor had ordered the streets to be paved, and the work was already begun when Sir R. Kerr Porter visited the city; other improvements were also going forward. Teflis has been long celebrated for its baths. Population about 15,000.

TEGEA, an ancient town of Peloponnesus, where Orestes' gigantic bones were found. It was famous for its temples to Apollo, Pan, Ceres, Proserpine, and Venus.

TEGEATES, a son of Lycaon, the founder of Tegea.

TEGUMENT, *n. s.* Lat. *tegumentum*. Cover; the outward part. A word seldom used but in anatomy or physics.

Clip and trim those tender strings in the fashion of beard, or other hairy teguments.

Broune's Vulgar Errors.

In the nutmeg another tegument is the mace between the green pericarpium and the hard shell.

Ray on the Creation.

Proceed by section, dividing the skin and separating the teguments.

Wiseman's Surgery.

TEHAMA, a belt of sand, which stretches along the eastern shore of the Red Sea, to the mountains of the interior. It is of varying but considerable breadth, and is probably augmented by the blowing of the moving sands, which ap-

pear to have encroached upon the limit of the sea. It is almost entirely barren, and bears every mark of having been anciently a part of the bed of the sea.

TEHRAUN, a large city of Persia, which, during the two last reigns, has been the capital of the empire. Its situation is striking, having to the south the ruins of the immense ancient city of Rey or Rae; to the north and east the lofty mountain ranges of Elburz and Demavend, and to the west a plain enriched with cultivation and villages. The modern city is about four miles in circumference, surrounded by a strong wall, flanked by innumerable towers, and a broad dry ditch, with a glacis. After being destroyed by the Afghans at the beginning of this century, it was rebuilt by Kurreen Khan, and enlarged by Agn Mahommed, who made it the seat of government. It has been still farther enlarged and adorned by his successor.

TEH-HE, *v. n.* A cant word made from the sound. To laugh with a loud and more insolent kind of cachinnation; to titter.

They laughed and *teh-he'd* with derision,
To see them take your deposition. *Hudibras.*

TEHUACAN, a town in the intendency of Mexico, and one of the most frequented ancient sanctuaries of the Mexicans. It has four principal churches, besides convents. The streets, houses, and squares are handsome. Long. 97° 14' 30" W., lat. 18° 30' N.

TEHUANTEPEC, TEGUANTEPEQUE, or TEOCOANTEPEQUE, a sea-port of Mexico, in the intendency of Oaxaca, in the bottom of the creek formed by the ocean, between the small villages of San Francisco, San Dionisio, and Santa Maria de la Mar. This port, impeded by a dangerous bar, may become of consequence, when navigation in general, and especially when the transport of the indigo of Guatemala, shall become more frequent by the Rio Guasacuallo. It is about 196 miles south-east of Mexico.

TEHUANTEPEC, a large open gulf in the front of the above city, from which it takes its name.

TEIGNMOUTH, EAST, a sea-port, township, and chapelry, in the parish of Dawlish, hundred of Exminster, Devon, near the mouth of the Teign, fifteen miles south of Exeter, and 187 west by south of London. The church or chapel is near the beach, and a venerable pile of Saxon architecture. This place has been much improved of late years, and is now become a place of fashionable resort for sea-bathing. The public rooms are in a neat brick building. The bathing machines are commodious, and here are two good inns. It has a considerable commerce in the export of pipe-clay to Bristol, Liverpool, &c. It also employs a great number of vessels in the Newfoundland fisheries.

TEIGNMOUTH, WEST, is divided from the above by the rivulet Tame. The old church was taken down in 1821, and a handsome octagonal edifice erected in its stead. This church is a curacy under Bishop's-Teignton, as that of East Teignton is under that of Dawlish, the incumbents of these parishes nominating the minister who serves the churches alternately. The theatre is a handsome new structure. The market-place has been lately built, and is very commodious

Across the Teign lies the delightful little village of Shaldon, containing several new lodging-houses. Market on Saturday. Fair September 29th. It is a member of the port of Exeter.

TEIL-TREE, *n. s.* Lat. *tilia*. The same with **LINDEN** or **LIME TREE**: which see.

A *teiltree* and an oak have their substance in them when they cast their leaves. *Isaiah vi. 13.*

TEIL TREE, in botany. See **TILIA**.

TEINT, *n. s.* Fr. *teinte*. Color; touch of the pencil.

Glazed colours have a vivacity which can never be imitated by the most brilliant colours, because the different *teints* are simply laid on, each in its place, one after another. *Dryden.*

TEINTS and **SEMITEINTS**, in painting, denote the several colors used in a picture, considered as more or less high, bright, deep, thin, or weakened and diminished, &c., to give the proper relieve, softness, or distance, &c., of the several objects.

TEJUCO, a district of Brasil, of which the town of Tejuco is the capital, around which it extends sixteen leagues from north to south, and about eight from east to west.

TEJUCOS, BAY OF, on the coast of Brasil, in South America, some miles to the north of the island of St. Catharine's. It is from two to three leagues across, and extends the same distance inland, being well sheltered, and affording good anchorage, and fine situations for loading timber. 'Along the beach of this bay,' observes Mr. Mawe, 'I found the shell of the murex genus, which produces that beautiful crimson dye so valued by the ancients. It is here called *purpura*, and, to my great surprise, its use is in some degree known to the natives, one of whom showed me some cotton fringe, dyed with an extract of it, though ill prepared. The shell is about the size of the common whelk, and contains a fish, on whose body appears a vesicle, full of a pale yellow, viscid, purulent substance, which constitutes the dye. The mode of extracting it, is to break the shell carefully with a hammer, so as not to crush the fish, and then let out the liquor in the vesicle with a lancet or other sharp instrument. I, for greater convenience, used a pen, and immediately wrote my initials, &c., on a handkerchief; the marks in half an hour after were of a dirty green color, and, on being exposed to the air a few hours longer, changed to a most rich crimson. The quantity produced by each animal is very small, but quite sufficient for such an experiment. The best time for making it is when the animal is in an incipient state of putrescency. I have not a doubt that if a sufficient quantity of them were taken, and the dyeing matter, when extracted, were liquified in a small degree with gum-water, a valuable article of commerce might be produced; at least the trial is worth making. The liquid is a perfect substantive dye, and of course resists the action of alkalis.' Lat. 26° 56' S.

TELAMON, a celebrated Grecian hero, the son of Æacus and Endeis, brother of Peleus and Phocus, and father of Teucer and Ajax. Having accidentally killed his brother Phocus he fled from Megara, his birth-place; and arriving at Salamis married Glaucè, the daughter of king

Cythereus, whom he succeeded. He was one of the Argonauts, and accompanied Hercules when he took Troy, who gave him the princess Hesione to wife.

TELAMONE, a town of Naples, the chief port of the Presidii, ten miles north of Orbitello. It is famous for the victories obtained by the Romans under the consuls C. A. Regulus and Æmilius Lepidus over the Gauls.

TEL'ARY, *adj.* Lat. *tela*, a web. Spinning webs.

The pictures of *telary* spiders, and their position in the web, is commonly made lateral, and regarding the horizon; although we shall commonly find it downward, and their heads respecting the centre.

Brown's Vulgar Errors.

TELCHINES, an ancient people of Rhodes, originally from Crete. They were the inventors of many useful arts, whence the poets fabled that they could change themselves into whatever shapes they pleased. *Diod.*

TELCHINIA, a territory of Crete, whence the Telchines emigrated to Rhodes.

TELCHIS, the son of Europus, and grandson of Ægialeus, one of the first kings of Peloponnesus.

TELEGONUS, a son of Ulysses, by Circe, born in Æea. He went to Ithaca to seek his father, but being shipwrecked on the coast he got into a quarrel with the people after landing, and killed his father in the squabble without knowing him, to his great grief upon the discovery. He afterwards founded Tusculum in Italy, and left a daughter, named Mamilia, from whom the Roman family of Mamilii claimed their name and descent.

TELEGRAPH (from *τηλε*, far off, and *γραφω*, to write), the name very properly given to an instrument by means of which information may be almost instantaneously conveyed to a considerable distance.

The telegraph, though it has been generally known and used by the moderns only for a few years, is perhaps not entirely a modern invention. There is reason to believe that amongst the Greeks there was some sort of telegraph in use. The burning of Troy is said to have been known in Greece very soon after it happened, and before any person had returned thence. But we have no certainty of this. The Chinese, when they send couriers on the great canal, or when any great man travels there, make signals by fire from one day's journey to another to have every thing prepared; and most of the barbarous nations used formerly to give the alarm of war by fires lighted on the hills or rising grounds. Polybius calls the different instruments used by the ancients for communicating information *πυρροσται*, *pyrsie*, because the signals were always made by fire. At first they communicated information of events merely by torches; but this method was of little use, because it was necessary before hand to fix the meaning of every particular signal. Æneas, a contemporary of Aristotle, who wrote a treatise on the duties of a general, endeavoured to correct those imperfections, but by no means succeeded. His method was defective, because it could not convey any other intelligence except what was written

on the sticks, and even that not exactly. With regard to all unforeseen events it was quite useless. A method was invented by Cleoxenus, or Democlitus, and very much improved by Polybius, as he himself informs us. This was by the letters of the Greek alphabet divided into five parts. But neither this nor any other method mentioned by the ancients seems ever to have been brought into general use.

The most ingenious of the moderns had not thought of such a machine as a telegraph till 1663, when the marquis of Worcester, in his *Century of Inventions*, affirmed that he had discovered 'a method by which, at a window, as far as eye can discover black from white, a man may hold discourse with his correspondent, without noise made or notice taken; being according to occasion given, or means afforded *ex re nata*, and no need of provision before hand; though much better if foreseen, and course taken by mutual consent of parties.' This could be done only by means of a telegraph, which in the next sentence is declared to have been rendered so perfect that by means of it the correspondence could be carried on 'by night as well as by day, though as dark as pitch is black.'

The first idea of a telegraph upon the modern construction, was suggested by Dr. Hooke towards the end of the last century. He gave the complete description of such a machine, as appears by the following extract, from a paper of his, read before the Royal Society on the 21st of May, 1684: 'I proposed,' says he, 'some years since, a method of discoursing at a distance, not by sound but by sight: I say that it is possible to convey intelligence from any one high and eminent place, to any other that is in sight of it, though thirty or forty miles distant, in as short a time almost as a man can write what he would have sent; and as suddenly to receive an answer, as he that receives it has a mind to return it, or can write it down on paper. Nay, by the help of three, four, or more eminent places visible to each other, lying in a straight line, 'tis possible to convey intelligence almost in a moment, to twice, or thrice, or more times that distance, with as great a certainty as by writing. For the performance of this, we must be beholden to a late invention, which we do not find any of the ancients knew; that is, the eye must be assisted with telescopes, that whatever characters are exposed at one station, may be made plain and distinguishable at the other. First: for the stations, if they be far distant, it will be necessary that they should be high, and lie exposed to the sky; that there be no higher hill or part of the earth beyond them, that may hinder the distinctness of the characters, which are to appear dark against the sky, beyond them appearing white, by which means also the vapors near the ground will be passed over and avoided. Next, in choosing these stations, care must be taken, as near as may be, that there be no hill that interposes between them, that is almost high enough to touch the visible ray, because in such cases the refraction of the air of that hill will be very apt to disturb the clear appearance of the object. The stations being found convenient, the next thing to be considered is, what telescopes will be necessary for each station.

One of these telescopes must be fixed at each extreme station, and two of them in each intermediate station; so that a man for each glass, sitting and looking through them, may plainly discover what is done in the next adjoining station, and with his pen write down on a paper the characters there exposed, in their due order; so that there ought to be two persons at each extreme station, and three at each intermediate one, that intelligence may be conveyed backwards and forwards at the same time. Next there must be certain times agreed on, when the correspondents are to expect it; or else there must be set at the top of a pole, in the morning, the hour appointed by either of the correspondents for acting that day.

'Next there must be convenient apparatus of characters, consisting of at least as many distinct characters as there are necessary letters in the alphabet (to be made use of as is expressed in plate TELEGRAPH, fig. 1). And these must be either day characters or night characters. If they are to be made use of in the day-time, they may all be made of deals, and of a size convenient for the several distances, any one of which characters may signify any one letter of the alphabet, and the whole alphabet may be varied 10,000 ways, so that none but the two extreme correspondents shall be able to discover the information conveyed. If the characters are for the night, then they may be made with links, or lights disposed in a certain order, which may be covered or uncovered, according to the method agreed on. There will be also requisite several other characters, which may for expedition express a whole sentence, such as 'I am ready to communicate;' 'I am ready to observe.' I could instance a hundred ways of facilitating the method of performing the design with the more dexterity and quickness, and with little change, but that I think will be needless at present, since, whenever such a way of correspondence shall be put in practice, those and many more than I can think of at present will of themselves occur, so that I do not in the least doubt but that with a little practice all things may be made so convenient, that the same character may be seen at Paris, within a minute after it hath been exposed in London; and that the characters may be exposed so quick after one another, that a composer shall not much exceed the exposer in swiftness, and this not only at the distance of one station, but of 100; for supposing all things ready at all of those several stations for observing and exposing as fast as the second observer doth read the characters of the first exposer, the second exposer will display them to the observer of the third station, whose exposer will likewise display them for the fourth observer, as fast as his observer doth name them to him or write them down. There may be many objections brought against this way of communication, because it has not yet been put in practice, but hardly any that may not be easily answered and obviated.'

Dr. Hooke thus illustrates his invention: let ABC (fig. 2) represent three very long masts or poles erected, E the top piece that joins them together, D a screen, behind which all the deal-board characters hang upon certain rods or lines, and may, by the help of small lines connected

with each of them, be exposed at T, or drawn back at D, as occasion shall require.

After this M. Amontons, a French academical, born in 1663, prepared a telegraph. His method was this:—Let there be people placed in several stations, at such a distance from one another that by the help of a telescope a man in one station may see a signal made in the next before him; he must immediately make the same signal that it may be seen by persons in the station next after him, who are to communicate it to those in the following station, and so on. Amontons tried this method in a small tract of land before several persons of the highest rank at the court of France.

It was not till the French revolution that the telegraph was applied to useful purposes. M. Chappe invented the telegraph first used by the French about the end of 1793, on principles nearly similar to those of Amontons. The manner of using this telegraph was as follows:—At the first station, which was on the roof of the palace of the Louvre at Paris, M. Chappe, the inventor, received in writing, from the committee of public safety, the words to be sent to Lisle, near which the French army then was. An upright post was erected on the Louvre, at the top of which were two transverse arms, moveable in all directions by a single piece of mechanism, and with inconceivable rapidity. He invented a number of positions for these arms which stood as signs for the letters of the alphabet; and these, for the greater celerity and simplicity, he reduced in number as much as possible. The intermediate operators were only instructed generally in sixteen signals; which were so distinct, so marked, so different the one from the other, that they were easily remembered. The construction of the machine was such that each signal was uniformly given in precisely the same manner at all times. M. Chappe having received at the Louvre the sentence to be conveyed, gave a known signal to the second station, which was Mont Martre, to prepare. At each station there was a watch tower, where telescopes were fixed, and the person on watch gave the signal of preparation which he had received, and this communicated successively through all the line, which brought them all into a state of readiness. The person at Mont Martre then received, letter by letter, the sentence from the Louvre, which he repeated with his own machine; and this was again repeated from the next height, with inconceivable rapidity, to the final station at Lisle. The first description of the telegraph was brought from Paris to Frankfort on the Maine by a *citoyen* member of the parliament of Bordeaux, who had seen that which was erected on the mountains of Belville.

Dr. Hutton has thus described his telegraph:—Let A A be a beam or mast of wood placed upright on a rising ground (fig. 3), which is about fifteen or sixteen feet high. B B is a beam or balance moving upon the centre A A. This balance-beam may be placed vertically or horizontally, or any how inclined, by

means of strong cords, which are fixed to the wheel D, on the edge of which is a double groove to receive the two cords. This balance is about eleven or twelve feet long and nine inches broad, having at the ends two pieces of wood, C, C, which likewise turn upon angles by means of four other cords that pass through the axis of the main balance, otherwise the balance would derange the cords; the pieces C are each about three feet long, and may be placed either to the right or left, straight or square, with the balance-beam. By means of these three the combination of movement is very extensive, remarkably simple, and easy to perform. Below is a small wooden hut, in which a person is employed to observe the movements of the machine. In the mountain nearest to this another person is to repeat these movements, and a third to write them down. The time taken up for each movement is twenty seconds; of which the motion alone is four seconds, the other sixteen the machine is stationary. Two working models of this instrument were executed at Frankfort, and sent by Mr. W. Playfair to the duke of York; and hence the plan and alphabet of the machine came to England. Various experiments were in consequence tried upon telegraphs in this country; and one was soon after set up by government in a chain of stations from the admiralty, London, to the sea coast. It consisted of six octagon boards, each of which was poised upon an axis in a frame in such a manner that it could be either placed vertically, so as to appear with its full size to the observer at the nearest station, as in fig. 4, or become invisible to him by being placed horizontally, as in fig. 5, so that the narrow edge alone would be exposed. Fig. 4 is a representation of this telegraph, with the parts all shut, and the machine ready to work. T, in the officer's cabin, is the telescope pointed to the next station. Fig. 3 is a representation of the machine not at work, and with the ports all open. The opening of the first port (fig. 4) expresses *a*, the second *b*, the third *c*, the fourth *d*, the fifth *e*, and the sixth *f*, &c. Six boards make thirty-six changes by the most plain and simple mode of working, and they will make many more if more were necessary.

Several other improvements have been proposed; but none, perhaps, of the telegraphs hitherto offered to the public exceeds the following either in simplicity, cheapness, or facility in working, and it might, with a few trifling additions, be made exceedingly distinct. It is thus described in the *Repertory of Arts*, vol. i. p. 382. For a nocturnal telegraph let there be four large patent reflectors, lying on the same plane, parallel to the horizon, placed on the top of an observatory. Let each of these reflectors be capable, by means of two winches, either of elevation or depression to a certain degree. By elevating or depressing one or two of the reflectors, eighteen very distinct arrangements may be produced, each reflector, after every arrangement, being restored to its place, as the following scheme will explain:—

A	B	D	E	F	G
° °°°	° °°°	° °°°	° °°°	°°° °	°°° °
I	K	L	M	N	O
°°° °	°°° °	°°° °°	°°° °°	°°° °°	°°° °°
P	R	S	T	U	Y
°°° °°	°°° °°	°°° °°	°°° °°	°°° °°	°°° °°

For the sake of example the above arrangements are made to answer to the most necessary letters of the alphabet; but alterations may be made at will, and a greater number of changes produced without any addition to the reflectors. In the first observatory there need only be a set of single reflectors; but in the others each reflector should be double, so as to face both the preceding and subsequent observatory; and each observatory should be furnished with two telescopes. The proper diameter of the reflectors, and their distance from each other, will be ascertained by experience. To convert this machine into a diurnal telegraph nothing is necessary but to insert, in the place of the reflectors, gilt balls, or any other conspicuous bodies.

In 1806 a new set of telegraphs was established on the whole extent of the coast of the French empire, of which the following description is given by captain C. W. Pasley, in the Philosophical Magazine. See figs. 6 and 7. Every telegraph consists of an upright post R, to which are attached three arms, A, B, and C, exactly similar to each other, and each moving upon its own distinct spindle or axis. The axis of one of these arms, A, is near the head of the post R; and the distance between the centres of motion of either of the two uppermost arms, and the centre of the one immediately below it, is rather less than double the length of one arm. The highest of the three arms A, can exhibit seven distinct positions, as is shown by the dotted lines A 1, A 2, A 3, &c.; but the other two arms B and C can only exhibit six positions each, because they are hidden by the post when in a vertical position. The total number of combinations, or of distinct signals, which can be made by this telegraph, will constantly be 391; but as the arm A, when in the vertical position A 4, may appear to be part of the post R, it is not safe to employ that position, and this will reduce the number of signals to 342. As only three bodies are employed in this telegraph, it appears very superior to the admiralty telegraphs used in England, which, by the combination of double that number of bodies, can only make sixty-three distinct signals. Captain Pasley observes, that the mechanism of the French telegraphs just described, must be either imperfect, or the men employed in working them must have been very unskilful, for the signals

were made and repeated in an awkward manner, with what seemed to him much unnecessary loss of time. But these defects, it will be evident, detract nothing from its merit as an invention. In regard to the mechanical construction, he could only observe that the arms, which were painted black, and appeared solid at a distance, were made in the fashion of a Venetian blind, in order, it may be presumed, to diminish the action of the wind in bad weather. Each arm had a counterpoise of thin materials painted white, which, unless the observer be very near the telegraph, becomes invisible.

Fig. 6 shows the telegraph in a state of rest, the dotted lines marking the several positions in which the arms can be exhibited. Fig. 7 is a specimen of the telegraph at work. Fig. 8 shows the construction of one of the arms on a larger scale, DE being the part which is fashioned like a Venetian blind, and EF the counterpoise.

Sir Home Popham's telegraph.—The original telegraphs at the admiralty, with the six boards, have been lately taken down, and a new kind substituted. It is on the same principle with the French, being an upright mast with two indicators, which move upon centres one above the other, in the manner of the last described. The mast is made to turn round on its vertical axis, so as to present its arm successively to all quarters, when required. The mechanism, which is the invention of Sir Home Popham, is the best that has ever been contrived, the movements being very simple, and effected by iron spindles and endless screws, so that the indices below are certain to accompany the indicators exactly in their movements, and place them precisely in their required positions, which cannot be done by the old machinery with cords, because they are liable to expand and contract by wet or dry weather. The machinery for this set of telegraphs was constructed in the most substantial manner by Maudslay in 1816. See figs. 9, 10, and 11. LM is a tall mast of an hexagonal form, framed up from six fir planks put together at the angles, and bound by iron hoops at different places, so as to be hollow within. The lower end L terminates in a pivot, and the mast is retained in a vertical position by a circular collar at O, which embraces it, and is supported in the roof of the building. The two arms P M and Q R are moveable upon centres, one at the top of the mast and the other half way down. When the arms are placed in the vertical position, they shut up within the hollow of the mast, so as to be entirely concealed; and for this purpose two of the six sides are cut away at the upper part, so as to leave an opening through the mast of sufficient width to admit the two arms to work in it. To communicate motion to the arms, a small toothed wheel is fixed upon each arm at the centre of motion, and close to the side of the arm. The teeth of these wheels are actuated by endless screws or worms, formed on the upper ends of the long spindles *de* and *fg*, which descend down to the bottom of the hollow mast, and have small bevelled wheels upon them, which are actuated by wheels of similar size, fixed on the ends of short horizontal spindles, which have handles *p, q*, applied at the extremi-

ties. See fig. 12. By turning these handles, motion is given to the vertical spindles *d* and *f*; and, by means of the endless screws upon the upper ends of them, the wheels at *M* and *R*, on the centres of the arms, are turned round, and the arms are put into any required position. But, in order that the people below may at all times know exactly what positions the arms stand in, two dials, *m* and *r*, are formed on the lower part of the mast, the upper one *m* being for the upper arm *M*, and the other *r* for the lower arm *R*; and each dial has an index or hand, which turns round with a motion exactly corresponding to the motion of the arms. For producing this motion, the axle of each hand or index has a small toothed wheel *s* or *t* (fig. 11) fixed upon it in the middle; and an endless screw is formed upon the upright spindle to work in the teeth of the wheel. The wheels upon the centre of the arms, and those upon the axes of the indices, have the same number of teeth; and, as every turn of the spindles and screws will move the wheels round one tooth, the angular motion of the arms *P M* and *Q R*, and the hands *m* and *r*, will in all cases be the same. The dials are each divided into eight, corresponding with the eight positions in which the arms are to be exhibited; viz. pointing vertically; 1st, upwards; and 2dly, downwards; pointing horizontally; 3dly, to the right; and 4thly, to the left: pointing upwards at an inclination of 45°; 5thly, to the right; and 6thly, to the left: pointing downwards at an inclination of 45°; 7thly, to the right; and 8thly, to the left. But of these eight positions, only the four last are made use of to represent characters; because, in the two vertical positions, the pointers enter within the mast, and cannot therefore be seen whether they are pointing upwards or downwards: the horizontal positions of the arms are reserved for the necessary signals of preparation, &c. Each arm, then, has four positions, in which it will express different signals; and these positions are all made with the pointer, at an inclination of 45° from the horizontal line.

These signals either express the letters of the alphabet, or the numeral characters, according to previous arrangement, which must be made known by exhibiting a preparatory signal, before the communication is begun. The signal to prepare for receiving letters is the lower arm extended horizontally to the right; and, for the numerals, both arms are extended horizontally to the left.

The upper pointer *P M* used by itself, at an elevation of 45°, denotes,

- A, or 1, when pointing upwards to the left.
- B, or 2, when pointing downwards to the left.
- C, or 3, when pointing upwards to the right.
- D, or 4, when pointing downwards to the right.

The lower pointer *Q R* used by itself, at an elevation of 45°, denotes,

- E, or 5, when pointing upwards to the left.
- F, or 6, when pointing downwards to the left.
- G, or 7, when pointing upwards to the right.
- H, or 8, when pointing downwards to the right.

It is easy to conceive that, by repeating all these positions with both arms exhibited together instead of one singly, various combinations may

be made, which are sufficient to express all the remaining letters, and some other necessary signals. The dial for each arm is double; that is, a dial is fixed at each side of the mast, and the axes of the indices or hands proceed quite through the mast, so as to have a hand at each end. These dials are not numbered exactly similar to each other, but are reversed; and the two indices on the opposite ends of the same axle, though they point in one direction, do not indicate the same numbers on the two dials; because each dial is adapted to indicate the meaning which the different positions of the arms will have, when the telegraph is viewed on that side to which the dial faces. For, when a signal is made, that arm which projects from the right-hand side, if the telegraph is examined on one side, will project on the left hand when the telegraph is viewed on the other side. It was stated before that the telegraph can be turned round, so as to present its arms to any direction. This is done by the pivot *L*, at the lower hand; but, to hold it fast in the desired direction, a circular iron plate is placed on the floor, with holes in it; and a bolt *W* is fitted into two eyes, which are fixed to the axle of the mast. The point of this bolt drops into any of the holes in the plate, and thus holds the mast firm; but if the bolt is lifted up, to draw its point out of the holes, it can be turned round. The arms are made with boards, like Venetian blinds; and each has a piece of cast-iron at the opposite end, to counterpoise the weight and make the arm move freely into all positions.

TELEMACHUS, the son of Ulysses and Penelope, was in the cradle when his father went with the rest of the Greeks to the Trojan war. When a child he fell into the sea, but was brought ashore by a dolphin. At the end of that war Telemachus went to seek his father; and as the place of his residence, and the cause of his long absence, were unknown, he visited the courts of Menelaus and Nestor to obtain information, accompanied by Minerva in the form of Mentor. He afterwards returned to Ithaca, where the suitors of Penelope had conspired to murder him, but he avoided their snares; and by means of Minerva he discovered his father, who had arrived in the island two days before him, and was then in the house of Eumæus. With this faithful servant and Ulysses, Telemachus consulted how to deliver his mother from the importunities of her suitors, and it was effected with great success. After his father's death he went to the island of *Ææa*, where he married Cassiphone the daughter of Circe, by whom he had a son called Latinus. He some time after had the misfortune to kill his mother-in-law Circe, and fled to Italy where he founded Clusium. From these stories, collected from Homer and the other poets, the celebrated Fenelon archbishop of Cambrai composed his well known *Adventures of Telemachus*; which, though not in verse, is justly esteemed a poem.

TELEPHASSA, the wife of Agenor, and mother of Cadmus, Phœnix, Cilix, and Europa. She died in Thrace, seeking her daughter Europa.

TELEPHIUM, true orpine, in botany, a ge-

mus of plants belonging to the class of pentandria, and order of trigynia; and in the natural system ranging under the fifty-fourth order, miscellanæ. The calyx is pentaphyllous; there are five petals, which are inserted into the receptacle; the capsule is unilocular and trivalvular. There are two species: 1. *T. imperati*; and 2. *T. oppositifolia*.

TELEPHUS, a son of Hercules by Auge, the daughter of Aleus. He was exposed as soon as born on mount Parthenis, but was preserved by a she goat and her shepherd. Auge, to avoid her father's rage, fled to Teuthras king of Mysia, and was by him adopted as his daughter. Mean time Telephus grew up, and on consulting the oracle as to his parentage, was advised to go to Mysia. Teuthras, being harassed by the depredations of Idas the son of Aphareus, offered his daughter Auge, and the succession to his crown, to any man who would repel Idas. Telephus undertook the task, and at the head of the Mysian troops conquered Idas, and claimed his reward. But, as he was just going to marry Auge, a monstrous serpent interrupted the ceremony; upon which, Auge imploring the aid of Hercules, the god appeared and told her that Telephus was her own son. After this Telephus became king of Mysia, married a daughter of Priam king of Troy, and assisted him in his war against the Greeks, a party of whom he defeated; but was mortally wounded by Achilles, who, however, was ordered by the oracle to cure him with the same spear that had wounded him. This Achilles did by the rust of the spear; and Telephus, in gratitude, joined the Greeks against the Trojans.—Paus. 8, c. 48; Diod. 4, &c.

TELESCOPE, *n. s.* } Fr. *telescope*; Gr. *τελος*
TELESCOPIC, or } and *σκοπεω*. A long
TELESCOPICAL, *adj.* } glass by which distant
objects are viewed: belonging to a telescope;
seeing at a distance.

The *telescope* discovers to us distant wonders in the heavens, and shews the milky way, and the bright cloudy spots, in a very dark sky, to be a collection of little stars. *Watts.*

Where Science points her *telescopic eye*,
Familiar with the wonders of the sky.

Couper.

TELESCOPE is derived from the Greek, *τηλε*, far off, and *σκοπειν*, to look at. This name is commonly appropriated to the larger sizes of the instrument, while the smaller are called perspective glasses, spy glasses, or opera glasses. A particular kind, which is thought to be much brighter than the rest, is called a night glass.

To what has been said on the invention of this most noble instrument, in the article OPTICS, we may add the following:—Mr. Leonard Digges, a gentleman of the seventeenth century, of great and various knowledge, asserts in his *Stratoticos*, and in another work, that his father, a military gentleman, had an instrument which he used in the field, by which he could bring distant objects near, and could know a man at the distance of three miles. He says, that when his father was at home he had often looked through it, and could distinguish the waving of the trees on the opposite side of the Severn. Mr. Digges resided near Bristol. Francis Fontana, in his *Celestial*

Observations, published at Naples in 1646, says, that he was assured by a Mr. Hardy, advocate of the parliament of Paris, a person of great learning and undoubted integrity, that on the death of his father there was found among his things an old tube, by which distant objects were distinctly seen; and that it was of a date long prior to the telescope lately invented, and had been kept by him as a secret. From the table and scheme which Sirturus has given us of the tools or dishes in which the spectacle-makers fashioned their glasses, that they had convex lenses formed to spheres of twenty-four inches diameter, and of eleven inferior sizes. He has given us a scheme of a set which he measured belonging to a spectacle-maker of the name of Rogette, at Corunna, in Spain; who, he says, had tools of the same sizes for concave glasses. It also appears that it was a general practice to use a convex and concave glass together. If any person should put together a twenty-four inch convex and a twelve inch concave (wrought on both sides) at the distance of six inches, he would have distinct vision, and the object would appear of double size. Concaves of six inches were not uncommon; and one such combined with the convex of twenty-four, at the distance of nine inches, would have distinct vision, and objects would be quadrupled in diameter. When such a thing occurred, it was natural to keep it as a curiosity, although the rationale of its operation was not understood. It is plain that Galileo's first telescope was of this kind, made up of such spectacle glasses as he could procure; for it magnified only three times in diameter; a thing easily procured by such glasses as he could find with every spectacle-maker. And he could not but observe, in his trials of their glasses, that the deeper concaves and flatter convexes he employed, he produced the greater amplification; and then he would find himself obliged to provide a tool not used by the spectacle-makers, viz. either a much flatter tool for a convex surface, or a much smaller sphere for a concave. His next telescope magnified but five times. But he groped his way with such spectacle-glasses as he could get, till he at last made tools for very flat object-glasses and very deep eye-glasses, and produced a telescope which magnified about twenty-five times. Sirturus saw it, and took the measures of it. He afterwards saw a scheme of it which Galileo had sent to a German prince at Inspruck, who had it drawn (that is, the circles for the tools) on a table on his gallery. The object-glass was a plano-convex, a portion of a sphere, of twenty-four inches diameter; the eye-glass was a double concave of two inches diameter; the focal distances were therefore twenty-four inches and one inch nearly. This must have been a very lucky operation, for Sirturus says, it was the best telescope he had seen; and we know that it requires the very best work to produce this magnifying power with such small spheres. Telescopes continued to be made in this way for many years; and Galileo never made them of any other form. Kepler published his *Dioptrics* in 1611; in which he tells us all that he or others had discovered of the law of refraction, viz. that in very small obliquities of

incidence, the angle of refraction was nearly one-third of the angle of incidence. This was indeed enough to have pointed out, with sufficient exactness, the construction of every optical instrument that we are even now possessed of; for this proportionality of the angles of incidence and refraction is assumed in the construction of the optical figure for all of them; and the deviation from it is still considered as the refinement of the art, and was not brought to any rule till fifty years after by Huyghens, and called by him aberration. Yet even the sagacious Kepler seems not to have seen the advantage of any other construction of the telescope; he just seems to acknowledge the possibility of it; and we are surprised to see writers giving him as the author of the astronomical telescope, or even as hinting at its construction. It is true, in the last proposition, he shows how a telescope may be made apparently with a convex eye-glass; but this is only a frivolous fancy; for the eye-glass is directed to be made convex externally, and a very deep concave on the inside; so that it is, in fact, a meniscus with the concavity prevalent. In the eighty-sixth proposition he indeed shows that it is possible so to place a convex glass behind another convex glass, that an eye shall see objects distinct, magnified, and inverted; and he speaks very sagaciously on the subject. After having said that an eye placed behind the point of union of the first glass, will see an object inverted, he shows that a small part only will be seen; and then he shows that a convex glass, duly proportioned and properly placed, will show more of it. But in showing this, he speaks in a way which shows evidently that he had formed no distinct notions of the manner in which this effect would be produced, only saying vaguely that the convergency of the second glass would counteract the divergency beyond the focus of the first. Had he conceived the matter with any tolerable distinctness, after seeing the great advantage of taking in a field greater in almost any proportion, he would have eagerly caught at the thought, and enlarged on the immense improvement. Had he but drawn one figure of the progress of the rays through two convex glasses, the whole would have been open to his view. This step, so easy and so important, was reserved for Scheiner, as has been observed under OPTICS; and the construction of this author, together with that of Jansen, are the models on which all refracting telescopes are now constructed; and in all that relates to their magnifying power, brightness, and field of vision, they may be constructed on Kepler's principle, that the angles of refraction are in a certain given proportion to the angles of incidence. But after Huyghens had applied his elegant geometry to the discovery of Snellius, viz. the proportionality, not of the angles, but of the sines, and had ascertained the aberrations from the foci of infinitely slender pencils, the reasons were clearly pointed out why there were such narrow limits naturally affixed to the performance of optical instruments, in consequence of the indistinctness of vision which resulted from constructions where the magnifying power, the quantity of light, or the field of vision, were extended beyond certain moderate bounds. The

theory of aberrations, which that most excellent geometer established, has enabled us to diminish this indistinctness arising from all these causes; and this diminution is the sole aim of all the different constructions which have been contrived since the days of Galileo and Scheiner.

The general aim, in the construction of a telescope, is to form, by means of mirrors or lenses, an image of the distant object, as large, as bright, and as extensive as is possible, consistently with distinctness; and then to view the image with a magnifying glass in any convenient manner. This gives us an arrangement of our subject. We shall first show the principles of construction of the object-glass or mirror, so as that it shall form an image of the distant object with these qualities; and then show how to construct the magnifying glass or eye-piece, so as to preserve them unimpaired. This indistinctness, which we wish to avoid, arises from two causes; the spherical figures of the refracting and reflecting surfaces, and the different refrangibility of the differently colored rays of light. The first may be called the spherical, and the second the chromatic indistinctness; and the deviations from the foci, determined by the elementary theorem, may be called the spherical and the chromatic aberrations. The limits of our work will not permit us to give any more of the doctrine of aberrations than is absolutely necessary for the construction of achromatic telescopes; and we refer the reader for a general view of the whole to Euler's Dioptrics, and other works of that kind. Dr. Smith has given as much as was necessary for the comparison of the merits of different glasses of similar construction, and in a very plain and elegant manner. His improvement of the fundamental theorem of that most elegant geometer Huyghens is as follows:—

I. IN REFLECTION. Let AVB (fig. 1, plate I., TELESCOPE) be a concave spherical mirror, of which C is the centre, V the vertex, CV the axis, and F the focus of an infinitely slender pencil of parallel rays passing through the centre. Let the ray aA , parallel to the axis, be reflected in AG, crossing the central ray CV in f . Let AP be the sine of the semi-aperture AV, AD its tangent, and CD its secant. The aberration Ff from the principal focus of central rays is equal to $\frac{1}{2}$ of the excess VD of the secant above the radius, or very near equal to $\frac{1}{2}$ of VP, the versed sine of the semi-aperture. For, because AD is perpendicular to CA, the points C, A, D, are in a circle, of which CD is the diameter; and because A f is equal to Cf, by reason of the equality of the angles fAB , fCA , and CA a , f is the centre of the circle through C, A, D, and fD is $= \frac{1}{2} CD$. But FC is $= \frac{1}{2} CV$; therefore Ff is $\frac{1}{2}$ of VD. But because DV : VP $=$ DC : VC, and DC is very little greater than VC when the aperture AB is moderate, DV is very little greater than VP, and Ff is very nearly equal to $\frac{1}{2}$ of VP. Cor. 1. The longitudinal aberration is $= \frac{AV^2}{4CN^2}$; for PV is very nearly $= \frac{AV^2}{2CV}$. Cor. 2. The lateral aberration FG is $= \frac{AV^3}{2CV^2}$. For FG : Ff $=$ AP : P, f $=$

AV : $\frac{1}{2}$ CV nearly, and therefore $FG = \frac{AV^3}{4CV} \times$

$\frac{2}{CV} = \frac{AV^3}{2CV^2}$ II. IN REFRACTIONS. Let

ABV (fig. 2 or 3) be a spherical surface separating two refracting substances, C the centre, V the vertex, AV the semi-aperture, AP its sine, PV its versed sine, and F the focus of parallel rays infinitely near to the axis. Let the extreme ray aA, parallel to the axis, be refracted into AG, crossing CF in f, which is therefore the focus of extreme parallel rays. The rectangle of the sine of incidence, by the difference of the sines of incidence and refraction, is to the square of the sine of refraction as the versed sine of the semi-aperture is to the longitudinal aberration of the extreme rays. Call the sine of incidence i, the sine of refraction r, and their difference d. Join CA, and about the centre f describe the arch AD. The angle ACV is equal to the angle of incidence, and CAf is the angle of refraction. Then, since the sine of incidence is to the sine of refraction as VF to CF, or as Af to Cf, that is, as Df to Cf, we have

$CF : FV = Cf : fD$

by conversion $CF : CV = Cf : CD$

altern. conver. $CF - Cf : CV - CD = CF : CV$

or . . . $Ff : VD = CF : CV = r : d$.

Now, $PV = \frac{AP^2}{CP + CV} = \frac{AP^2}{2CV}$ nearly, and

$PD = \frac{AP^2}{fP + fV} = \frac{AP^2}{2fV}$ nearly, $= \frac{AP^2}{2FV}$

nearly. Therefore $PV : PD = FV : CV$, and $DV : PV = CF : FV$ nearly.

We had above $Ff : VD = r : d$;
and now $VD : PV = CF : FV = r : i$;
therefore $Ff : PV = r^2 : di$,

and $Ff = \frac{r^2}{di} \times PV$. Q. E. D. The aberration will be different according as the refraction is made towards or from the perpendicular; that is, according as r is less or greater than i. They are in the ratio of $\frac{r^2}{di}$ to $\frac{i^2}{dr}$, or of r^3 to i^3 . The

aberration therefore is always much diminished when the refraction is made from a rare into a dense medium. The proportion of the sines for air and glass is nearly that of 3 to 2. When the light is refracted into the glass, the aberration is nearly $\frac{1}{4}$ of PV; and, when the light passes out of glass into air, it is about $\frac{1}{3}$ of PV. Cor. 1. $Ff = \frac{r^2}{di} \times \frac{AP^2}{2CV}$ nearly, and it is also $= \frac{r^2}{d^2} \times \frac{AP^2}{2FV}$,

because $PV = \frac{AP^2}{2CV}$ nearly, and $i : d = FV :$

CV. Cor. 2. Because $fPPA = Ff : FG$

or $FV : AV = Ff : FG$ nearly,

we have $FG, \text{ the lateral aberration, } = Ff \times$

$\frac{AV}{FV} = \frac{r^2}{d^2} \times \frac{AV^3}{2FV^3} = \frac{r^2}{i^2} \times \frac{AV^3}{2CV^2}$. Cor. 3.

Because the angle FAf is proportional to $\frac{FG}{FV}$

very nearly, we have the angular aberration FAf

$= \frac{r^2}{d^2} \times \frac{AV^3}{2FV^3} = \frac{r}{i^2} \times \frac{AV^3}{2CV^3}$. In general,

the longitudinal aberrations from the focus of central parallel rays are as the squares of the apertures directly, and as the focal distances inversely; and the lateral aberrations are as the cubes of the apertures directly, and the squares of the focal distances inversely; and the angular aberrations are as the cubes of the aperture directly, and the cubes of the focal distances inversely. To simplify the investigation, some small errors are admitted. PV and PD are not in the exact proportion that we assumed them, nor is Df equal to FV. But in the small apertures which suffice for optical instruments, these errors may be disregarded.

This spherical aberration produces an indistinctness of vision in the same manner as the chromatic aberration does; viz. by spreading out every mathematical point of the object into a little spot in its picture; which spots, by mixing with each other, confuse the whole. We must now determine the diameter of the circle of diffusion. Let a ray βa (fig. 4) be refracted on the other side of the axis into a H ϕ , cutting AfG in H, and draw the perpendicular EH. Call AV a, aV a, VV f (or VF, or V ϕ , which in this comparison may be taken as equal) = f, Ff = b, and fE = ϕx . $AV^2 : aV^2 = Ff :$

$F\phi$ (already demonstrated) and $F\phi = \frac{a^2}{a^2} b$, and

$Ff - F\phi$ (or $f\phi$) $= b - \frac{a^2}{a^2} b = \frac{a^2b - a^2b}{a^2} =$

$\frac{b}{a^2} \times a^2 - a^2 = \frac{b}{a^2} \times \overline{a+a} \times \overline{a-a}$. Also

$Pf : PA = fE : EH$ or $f : a = x : \frac{ax}{f} = EH$.

And $P\pi : P\phi = EH : E\phi$ or $a : f = \frac{ax}{f} : \frac{ax}{a}$,

$= E\phi$. Therefore $f\phi = \frac{ax}{a} + x = \frac{a+ax}{a}$,

$= \frac{x}{a} \times \overline{a+a}$. Therefore $\frac{x}{a} \times \overline{a+a} = \frac{b}{a^2} \times$

$\overline{a+a} \times \overline{a-a}$, and $\frac{x}{a} = \frac{b}{a^2} \times \overline{a-a}$, and $x = \frac{b}{a^2}$

$\times a(a-a)$. Therefore x is greatest when a

$\times \overline{a-a}$ is greatest; that is when $a = \frac{1}{2} a$.

Therefore EH is greatest when P π is equal to the half of AP. When this is the case we have

at the same time $\frac{b}{a^2} \times a(a-a) = \frac{b}{a^2} \times \frac{1}{4} a^2$,

and $x = \frac{1}{4} b$, or $EH = \frac{1}{4} FG$. That is, the diameter of the circle of aberration, through which

the whole of the refracted light must pass, is one-fourth of the diameter of the circle of aberration at the focus of parallel central rays. In

the chromatic aberration it was one-half; so that in this respect the spherical aberration does not create so great confusion as the chromatic. We

are now able to compare them, since we have now the measure of both the circles of aberration. It has not been found possible to give more than

four inches of aperture to an object glass of 100 feet focal distance, so as to preserve sufficient distinctness. If we compute the diameter of the

circle EH, corresponding to this aperture, we shall find it not much to exceed $\frac{1}{10000}$ of an inch.

If we restrict the circle of chromatic dispersion to $\frac{1}{20}$ of the aperture, which is hardly the fifth

part of the whole dispersion in it, it is $\frac{1}{62\frac{1}{2}}$ of an inch, and is about 1900 times greater than the other. The circle of the spherical aberration of a plano-convex lens, with the plane side next the distant object, is equal to the circle of chromatic dispersion when the semi-aperture is about 15°: for we saw formerly that F H is one-fourth of F G, and that F G is $= \frac{r^2}{2} \frac{A P^3}{2 A C^2}$, and therefore

$$E G = \frac{r^2}{2} \times \frac{A P^3}{8 A C^2}. \text{ This being made } = \frac{A P}{55},$$

gives us $A P = \sqrt{\frac{8 i^2 A C^2}{55 r^2}}$, which is nearly $\frac{A C}{4}$, and corresponds to an aperture of 30° diameter, if r be to i as 3 to 2. Sir Isaac Newton

was therefore well entitled to say that it was quite needless to attempt figures which should have less aberration than spherical ones, while the confusion produced by the chromatic dispersion remained uncorrected. Since the indistinctness is as the squares of the diameters of the circles of aberration, the disproportion is quite beyond our imagination, even when Newton has made such a liberal allowance to the chromatic dispersion. But it must be acknowledged that he has not attended to the distribution of the light in the circle of spherical aberration, and has hastily supposed it to be like the distribution of the colored light, indefinitely rare in the margin and denser in the centre. We are indebted to abbé Boscovich for the elegant determination of this distribution, which we have given in the article OPTICS. From this it appears that the light in the margin of the circle of spherical aberration, instead of being incomparably rarer than in the spaces between it and the centre, is incomparably denser. The indistinctness, therefore, produced by the intersection of these luminous circumferences is vastly great, and increases the whole indistinctness exceedingly. By a gross calculation it appears to be increased at least 500 times. The proportional indistinctness therefore, instead of being 1900² to 1, is only $\frac{1900^2}{500}$,

or nearly 7220 to 1; a proportion still sufficiently great to warrant Newton's preference of the reflecting telescope of his invention. And we may now observe that the reflecting telescope has even a great advantage over a refracting one of the same focal distance with respect to its spherical aberration: for we have seen (Cor. 2.) that

the lateral aberration is $\frac{r^2}{2} \frac{A V^3}{2 C V^2}$. This for a

plano-convex glass is nearly $\frac{9}{4} \frac{A V^3}{2 C V^2}$. And the diameter of the circle of aberration is one-fourth of this, or $\frac{9}{16} \times \frac{A V^3}{2 C V^2}$. In like manner

the lateral aberration of a convave mirror is $\frac{A V^3}{2 C V^2}$; and the diameter of the circle of dispersion is $\frac{A V^3}{8 C V^2}$; and therefore, if the surfaces were portions of the same sphere, the

diameter of the circle of aberration of refracted rays would be to that of the circle of aberration of reflected rays as $\frac{9}{16}$ to $\frac{1}{4}$, or as nine to four. But when the refracting and reflecting surfaces, in the position here considered, have the same focal distance, the radius of the refracting surface is four times that of the reflecting surface. The proportion of the diameters of the circles of spherical aberration is that of 9×4^2 to 4, or of 144 to 4, or 36 to 1. The distinctness, therefore, of the reflector is 36×36 , or 1296 times greater than that of a plano-convex lens (placed with the plane side next the distant object), of the same breadth and focal distance, and will therefore admit of a much greater magnifying power. This comparison is indeed made in circumstances most favorable to the reflector, because this is the very worst position of a plano-convex lens. But we have not as yet learned the aberration in any other position. In another position the refraction and consequent aberration of both surfaces are complicated. Before we proceed to the consideration of this very difficult subject, we may deduce from what has been already demonstrated, several general rules and maxims, in the construction of telescopes, which will explain (to such readers as do not wish to enter more deeply into the subject) and justify the proportion which long practice of the best artists has sanctioned. Indistinctness proceeds from the commixture of the circles of aberration on the retina of the eye. For any one sensible point of the retina, being the centre of a circle of aberration, will at once be affected by the admixture of the rays of as many different pencils of light as there are sensible points in the area of that circle, and will convey to the mind a mixed sensation of as many visible points of the object. This number will be as the area of the circle of aberrations, whatever be the size of a sensible point of the retina. Now, in vision with telescopes, the diameter of the circle of aberration on the retina is as the apparent magnitude of the diameter of the corresponding circle in the focus of the eye-glass; that is, as the angle subtended by this diameter at the centre of the eye-glass; that is, as the diameter itself directly, and as the focal distance of the eye glass inversely. And the area of that circle on the retina is as the area of the circle in the focus of the eye-glass directly, and as the square of the focal distance of the eye-glass inversely. And this is the measure of the apparent indistinctness. COR. In all sorts of telescopes, and also in compound microscopes, an object is seen equally distinct when the focal distance of the eye-glasses are proportional to the diameters of the circles of aberration in the focus of the object glass. Here we do not consider the trifling alteration which well-constructed eye-glasses may add to the indistinctness of the first image. In refracting telescopes, the apparent indistinctness is as the area of the object-glass directly, and as the square of the focal distance of the eye-glass inversely. For it has been shown that the area of the circle of dispersion is as the area of the object-glass, and that the spherical aberration is insignificant when compared with this. Therefore, to make reflecting telescopes equally distinct, the diameter

of the object-glass must be proportional to the focal distance of the eye-glass. But, in reflecting telescopes, the indistinctness is as the sixth power of the aperture of the object-glass directly, and as the fourth power of the focal distance of the object-glass, and square of the focal distance of the eye-glass, inversely. This is evident from the dimensions of the circle of aberration, which was found proportional to $\frac{AV^3}{CV^2}$. Therefore, to have

them equally distinct, the cubes of the apertures must be proportional to the squares of the focal distance multiplied by the focal distance of the eye-glass. By these rules, and a standard telescope of approved goodness, an artist can always proportion the parts of any instrument he wishes to construct. Mr. Huyghens made one, of which the object-glass had thirty-feet focal distance and three inches diameter. The eye-glass had 3·3 inches focal distance. And its performance was found superior to any which he had seen: nor did this appear owing to any chance goodness of the object-glass, because he found others equally good which were constructed on similar proportions. This has therefore been adopted as a standard. We should now proceed to the most difficult part of our subject, the compound aberrations of different surfaces. But our limits will not permit us to enlarge on this deep subject. We must therefore refer to what we have said upon it under the article OPTICS. We may also recommend to the curious reader Clairault's *Dissertations*, in the *Memoirs of the Academy of Paris*, 1756, &c.; those of Boscovich in the *Memoirs of the Academy of Bologna*, and in his five volumes of *Opuscula*, published at Bassano in 1785, and those of D'Alembert and Euler. The only treatise in our language is the translation of a very imperfect work by Scharter. In what follows, we shall, however, give a general view of it.

Estimate of the dispersive power of the refracting telescope.—The separation of the red, violet, and intervening rays, is called *dispersion*; and, although this arises merely from a difference of the refractive power in respect of the different rays, it is convenient to distinguish this particular modification of the refractive power by a name, and we call it the *dispersive power* of the refracting substance. It is susceptible of degrees; for a piece of flint-glass will refract the light, so that, when the sine of refraction of the red ray is 77, the sine of the refraction of the violet ray is nearly $78\frac{1}{2}$; or if the sine of refraction of the red ray, measured on a particular scale, is 1·54, the sine of refraction of the violet ray is 1·57. The dispersion of this substance, being measured by the difference of the extreme sines of refraction, is greater than the dispersion of the other glass, in the proportion of three to two. But this alone is not a sufficient measure of the absolute dispersive power of a substance. Although the ratio of 1·54 to 1·56 remains constant, whatever the real magnitude of the refractions of common glass may be; and though we therefore say that its dispersive power is constant, we know that, by increasing the incidence and the refractions, the absolute dispersion is also increased. Another substance shows the same properties, and in a particular

case may produce the same dispersion; yet it has not, for this sole reason, the same dispersive power. If indeed the incidence and the refraction of the mean ray be also the same, the dispersive power cannot be said to differ; but, if the incidence and the refraction of the mean ray be less, the dispersive power must be considered as greater, though the actual dispersion be the same; because, if we increase the incidence till it becomes equal to that in the common glass, the dispersion will now be increased. The proper way of conceiving the dispersion, therefore, is to consider it as a portion of the whole refraction; and, if we find a substance making the same dispersion with half the general refraction, we must say that the dispersive quality is double; because, by making the refraction equal, the dispersion will really be double. If therefore we take m as a symbol of the separation of the

extreme rays from the middle ray, $\frac{m}{m-1}$ is the natural measure of the dispersive power. We shall express this in the Leibnitzian notation thus, $\frac{dm}{m-1}$, that we may avoid the indistinctness which the Newtonian notation would occasion when m is changed for m' or m'' . It is not unusual for optical writers to take the whole separation of the red and violet rays for the measure of the dispersive power, and to compare this with the refracting power, with respect to one of the extreme rays. But it is surely better to consider the mean refraction as the measure of the refracting power; and the deviation of either of the extremes from this mean is a proper enough measure of the dispersion, being always half of it. It is attended with this convenience, that, being introduced into our computations as a quantity infinitely small, and treated as such for the ease of computation, while it is really a quantity of sensible magnitude; the errors arising from this supposition are diminished greatly by taking one-half of the deviation and comparing it with the mean refraction. This method has, however, this inconvenience, that it does not exhibit at once the refractive power in all substances respecting any particular color of light; for it is not the ray of any particular color that suffers the mean refraction. In common glass it is the ray which is in the confines of the yellow and blue; in flint glass it is nearly the middle blue ray; and in other substances it is a different ray. These circumstances appear plainly in the different proportions of the colors of the prismatic spectrum exhibited by different substances. This is a great bar to the perfection of achromatic instruments.

Method of constructing an achromatic lens.—The way in which an achromatic lens is constructed is, to make use of a contrary refraction of a second lens to destroy the dispersion or spherical aberration of the first. The first purpose will be answered if $\frac{dm}{n}$ be equal to $\frac{dm'}{n'}$. For, in order that the different colored rays may be collected into one point by two lenses, it is only necessary that $\frac{1}{f}$ the reci-

Fig. 4.

Fig. 3.

Fig. 1.

Fig. 2.

procal of the focal distance of rays refracted by both, may be the same for the extreme and mean rays, that is, that $\frac{m+d}{n} + \frac{m-1}{n}$ + $\frac{m'+d}{n'}$ + $\frac{m'-1}{n'}$

+ $\frac{1}{r}$ be of the same value with $\frac{m-1}{n} + \frac{m'-1}{n'}$ + $\frac{1}{r}$; which must happen if $\frac{d}{n} + \frac{d'}{n'}$ be =

0, or $\frac{d}{n} = -\frac{d'}{n'}$. This may be seen in another way, more comprehensible by such as are not versant in these discussions.

In order that the extreme colors, which are separated by the first lens, may be rendered parallel by the second; we have shown already that n and n' are proportional to the radii of the equivalent isosceles lenses, being the halves of these radii. They are therefore (in these small refractions) inversely proportional to the angles formed by the surfaces at the edges of the lenses; n' may therefore be taken for the angle of the first lens, and n for that of the second. Now the small refraction by a prism, whose angle (also small) is n' , is $m-1 \times n'$. The dispersive power being now substituted for the refractive power, we have for this refraction of the prism $d m \times n'$. This must be destroyed by the opposite refraction of the other prism $d' m' \times n$. Therefore $d m \times n' = d' m' \times n$, or $\frac{d m}{n} = -\frac{d' m'}{n'}$. In like manner, this effect will

be produced by three lenses if $\frac{d}{n} + \frac{d'}{n'}$ + $\frac{d''}{n''}$ be = 0, &c. Lastly, the errors arising from the spherical figure, which we expressed by $-R^2(q+q')$ will be corrected if $q+q'$ be = 0.

Method of constructing a double achromatic object-glass.—Here we have to determine four radii, $a, b, a',$ and b' . Make $n = 1$. This greatly simplifies the calculus, by exterminating it from all the denominators. This gives

for the equation $\frac{d}{n} + \frac{d'}{n'} = 0$, the equation

$d m + \frac{d m'}{n'} = 0$, or $d m = -\frac{d m'}{n'}$, and $\frac{1}{n'} =$

$-\frac{d m}{d m'}$. Also we have r' , the focal distance of the light incident on the second lens, the same with the principal focal distance p of the first lens (neglecting the interval, if any). Now $\frac{1}{p} = \frac{m-1}{n}$, which in the present case

is $= m-1$. Also $\frac{1}{p}$ is $= -u(m-1)$, and $\frac{1}{p} =$

$m-1 - u(m'-1) = u'$. Make these substitutions in the values of $\frac{q}{m-1}$ and $\frac{q'}{m'-1}$,

and we obtain the following equation: $c m^2 -$

$\frac{c(m+2)}{a} + \frac{c(m+2)}{m a^2} - u^3 m^2 - \frac{u^2(2m'+1)}{a}$

$-\frac{u(m'+2)}{m' a^2} + u^2(3m'+1)(m-1) +$

$\frac{4u(m'+1)(m-1)}{m' a} - \frac{u(3m'+2)(m-1)}{m'} = 0$.

Arrange these terms in order, according as they

are factors of $\frac{1}{a^2}, \frac{1}{a}, \frac{1}{a^2}, \frac{1}{a}$, or independent quantities. It puts on this form: $\frac{c(m+2)}{m} \times$

$\frac{1}{a^2} - c(2m+1) \times \frac{1}{a} - \frac{u(m'+2)}{m'} \times \frac{1}{a^2} - (u^2$

$(2m'+1) - \frac{4u(m'+1)(m-1)}{m'} \times \frac{1}{a} +$

$c m^2 + u^2(3m'+1)(m-1) - u^3 m^2 -$

$\frac{u(3m'+2)(m-1)^2}{m'} = 0$. Let A be the coef-

ficient of $\frac{1}{a^2}$, B that of $\frac{1}{a}$, C that of $\frac{1}{a^2}$, D that

of $\frac{1}{a}$, and E the sum of the independent quanti-

ty: that is, let A be $= \frac{c(m+2)}{m}$, B $= c(2m+1)$,

C $= \frac{u(m'+2)}{m'}$, D $= u^2(2m'+2) -$

$\frac{4u(m'+1)(m-1)}{m}$, and E $= c m^2 + u^2(3m'+1)$

$(m-1) - u^3 m^2 - \frac{u(3m'+2)(m-1)^2}{m'}$. Our

final equation becomes $\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a^2} - \frac{D}{a} + E = 0$.

The coefficients of this equation and the independent quantity are all known, from our knowledge of m, m', d, d' ; and we are to find the values of a and a' , and from them $n = 1$ to find the values of b and b' . But it is evidently an indeterminate equation, because there are two unknown quantities; so that there may be an infinity of solutions. It must be rendered determinate by means of some other conditions to which it may be subjected. These conditions must depend on some other circumstance which may direct our choice. One circumstance occurs which we think of very great consequence. In the passage of light from one substance to another, there is always a considerable portion reflected from the posterior surface of the first and from the anterior surface of the last; and this reflection is more copious in proportion to the refraction. This loss of light will therefore be diminished by making the internal surfaces of the lenses to coincide; that is, by making $b = d$. This will be attended with another advantage. If we put between the glasses a substance of nearly the same refracting power, we shall not only completely prevent this loss of light, but we shall greatly diminish the errors which arise from an imperfect polish of the surfaces. We have tried this, and find the effect very surprising. The lens, being polished immediately after the figure has been given it, and while it was almost impervious to light by reason of its roughness, which was still sensible to the naked eye, performed as well as when finished in the finest manner. This condition, by taking away one refraction, obliges us to increase those which remain, and therefore increases the spherical aberrations. And since our formulæ do not fully remove those (by reason of the small quantities neglected in the process), it is uncertain whether this condition be the most eligible. We have, however, no direct argument to the contrary. By

comparing this object-glass with the former, we may remark, that diminishing a a little increases b , and in this respect improves the lens. It indeed has diminished B' , but this being already considerable no inconvenience attends this diminution. But we learn, at the same time, that the advantage must be very small; for we cannot diminish a much more, without making it as small as the smallest radius of the object-glass. This proportion is therefore very near the maximum, or best possible; and we know that in such cases, even considerable changes in the radii will make but small changes in the result: for these reasons we are disposed to give a strong preference to the first construction, on account of the other advantages which we showed to attend it. As another example, we may take a case which is very nearly the general practice of the London artists. The radius of curvature for the anterior surface of the convex crown glass is five-sixths of the radius of the posterior surface, so that $h = \frac{5}{6}$. This, being introduced into the determinate equation, gives

$$\begin{matrix} a = 0.2938 & a' = -0.3447 \\ b = -0.3526 & b = 1.1474 \end{matrix}$$

Method of constructing a triple achromatic object-glass.—It is plain that there are more conditions to be assumed before we can render this a determinate problem, and that the investigation must be more intricate. At the same time, it must give us a much greater variety of constructions, in consequence of our having more conditions necessary for giving the equation this determinate form. Our limits will not allow us to give a full account of all that may be done in this method. We shall therefore content ourselves with giving one case which will sufficiently point out the method of proceeding. We shall then give the results in some other eligible cases, as rules to artists by which they may construct such glasses. Let the first and second glasses be of equal curvatures on both sides; the first being a double convex of crown-glass, and the second a double concave of flint-glass. Still making n the unit of our calculus, we have in the first place $a = -b, = -a', = b'$. Therefore $\frac{1}{a} - \frac{1}{b} = -(\frac{1}{a} - \frac{1}{b})$, or $\frac{1}{n'} = -\frac{1}{n} = -1$. Therefore the equation $\frac{dm}{n} + \frac{dm'}{n'} + \frac{dm''}{n''} = 0$ becomes $u - 1 + \frac{u}{n''} = 0$, or $\frac{1}{n''} = \frac{1}{u} - 1$. Let us call this value u' . We have $\frac{1}{p} = m - 1; \frac{1}{p'} = -(m' - 1); \frac{1}{p''} = u'(m - 1); \frac{1}{p''} = \frac{1}{p} + \frac{1}{p'} + \frac{1}{p''} = m - m' + u'(m - 1)$. And, if we make $m' - m = C'$, we shall have $\frac{1}{p} = -C, + u'(m - 1)$. Also $\frac{1}{r'} = m - 1; \frac{1}{r''} = m - 1 - (m' - 1), = m - m', = -C'$. The equality of the two curvatures of each lens gives $\frac{i}{a} = \frac{1}{2}$. There-

fore $\frac{1}{a} = -\frac{1}{b}, = -\frac{1}{a'}, = \frac{1}{b'}, = \frac{1}{2}$; and $\frac{1}{b''} = \frac{1}{a''} - \frac{1}{n''}, = \frac{1}{a''} u'$. Substituting these values in the equation, we obtain the three formulæ:

$$\begin{aligned} 1. & -c m^2 - \frac{1}{2} c (2m + 1) + \frac{c(m + 2)}{4m} \\ 2. & -m' 2 + \frac{1}{2} (2m' + 1) - \frac{m' + 2}{4m'} + \\ & (3m' + 1)(m - 1) - \frac{2(m' + 1)(m - 1)}{m'} \\ & - \frac{(3m' + 2)(m - 1)^2}{m'} \\ 3. & c u' 3m^2 - \frac{c u'^2 (2m + 1)}{a''} + \frac{c u' (m + 2)}{m a''^2} \\ & - c' c' u'^2 (3m + 1) + \frac{4 c c' u' (m + 1)}{m a''} \\ & + \frac{c c'^2 u' (3m + 2)}{m} = 0. \end{aligned}$$

Now arrange these quantities according as they are coefficients of $\frac{1}{a''^2}$ and of $\frac{1}{a''}$, or independent quantities. Let the coefficient of $\frac{1}{a''^2}$ be A , that of $\frac{1}{a''}$ be B , and the independent quantity be C ; we have $A = \frac{c u' (m + 2)}{m}, B = c u'^2 (2m + 1) - \frac{4 c c' u' (m + 1)}{m}$, and $C = c m^2 + \frac{c(m + 2)}{4m} + \frac{1}{2} (2m' + 1) + (3m + 1)(m - 1) + c u'^3 m^2 + \frac{c c'^2 u' (3m + 2)}{m} - \frac{1}{2} c (2m + 1) - m'^2 - \frac{m' + 2}{4m} - \frac{2(m' + 1)(m - 1)}{m'} - \frac{(3m' + 2)(m - 1)^2}{m'}$. Our equation now becomes $\frac{A}{a''^2} - \frac{B}{a''} + C = 0$. This reduced to numbers, by computing the values of the coefficients, is $\frac{1.312}{a''^2} - \frac{1.207}{a''} + 0.3257 = 0$. This, divided by 1.312, gives $s = -0.92$; and $t = -0.2482$; $-\frac{1}{4} s = 0.46$; $\frac{1}{4} s^2 = 0.2116$; and $\sqrt{\frac{1}{4} s^2 - t} = \pm 0.6781$. And, finally, $\frac{1}{a''} = 0.46 \pm 0.6781$.

This has two roots, viz. 0.2181 and -1.1381 . The last would give a very small radius, and is therefore rejected. Now, proceeding with this value of $\frac{1}{a''}$ and the $\frac{1}{n''}$, we get the other radius b'' , and then, by means of u' , we get the other radius which is common to the four surfaces. Then, by $\frac{1}{p} = \frac{1}{p''} - c'$, we get the value of P .

The radii being all on the scale of which n is the unit, they must be divided by P to obtain their value on the scale which has P for its unit. They will give us

$$\begin{matrix} a = -b, = -a', = b', = 0.530 \\ a'' = 1.215 \\ b'' = -0.3046 \\ P = 1 \end{matrix}$$

Upon the whole, an amateur has little chance of succeeding in these attempts. The diversity of glasses, and the uncertainty of the workman's producing the very curvatures which he intends, is so great, that the object-glass turns out different from his expectation. The artist who makes great numbers acquires a pretty certain guess at the remaining error; and, having many lenses, intended to be of one form, but unavoidably differing a little from it, he tries several of them with the other two, and, finding one better than the rest, he makes use of it to complete the set. The great difficulty in the construction is to find the exact proportion of the dispersive powers of the crown and flint glass. The crown is pretty constant; but there are hardly two pots of flint glass which have the same dispersive power. Even if constant, it is difficult to measure it accurately; and an error in this greatly affects the instrument, because the focal distances of the lenses must be nearly as their dispersive powers. The best method of examining this is as follows: The sun's light, or that of a brilliant lamp, passed through a small hole in a board, and fell on another board pierced also with a small hole. Behind this was placed a fine prism *A* fig. 5, which formed, a spectrum *ROV* on a screen pierced with a small hole. Behind this was placed a prism *B* of the substance under examination. The ray which was refracted by it fell on the wall at *D*, and the distance of its illumination from that point to *C*, on which an unrefracted ray would have fallen, was carefully measured. This showed the refraction of that color. Then, in order that we might be certain that we always compared the refraction of the same precise color by the different prisms placed at *B*, we marked the precise position of the prism *A* when the ray of a particular color fell on the prism *B*. This was done by an index *AG* attached to *A*, and turning with it, when we caused the different colors of the spectrum formed by *A* to fall on *B*. Having examined one prism *B* with respect to all the colors in the spectrum formed by *A*, we put another *B* in its place. Then bringing *A* to all its former positions successively, by means of a graduated arch *HGK*, we were certain that when the index was at the same division of the arch, it was the very ray which had been made to pass through the first prism *B* in a former experiment. We did not solicitously endeavour to find the very extreme red and violet rays; because, although we did not learn the whole dispersions of the two prisms, we learned their proportions, which is the circumstance wanted in the construction of achromatic glasses. It is in vain to attempt this by measuring the spectrums themselves; for we cannot be certain of selecting the very same colors for the comparison, because they succeeded in an insensible gradation. We have hitherto proceeded on the supposition that when, by means of contrary refractions, we have united the extreme red and violet rays, we have also united all the others. But this is quite gratuitous. Sir Isaac Newton would, however, have made the same supposition; for he imagined that the different colors divided the spectrum formed by all substances in the proportions of a musical canon. This is

a mistake. When a spectrum is formed by a prism of crown glass, and another of precisely the same length is formed by the side of it by a prism of flint glass, the cosine between the green and blue will be found precisely in the middle of the first spectrum, but in the second it will be considerably nearer to the red extremity. In short, different substances do not disperse the colors in the same proportion. The effect of this irrationality (so to call it) of dispersion, will appear plainly. Let *A*, fig. 6, represent a spot of white solar light falling perpendicularly on a wall. Suppose a prism of common glass placed behind the hole through which the light is admitted, with its refracting angle facing the left hand. It will refract the beam of light to the right, and will at the same time disperse this heterogeneous light into its component rays, carrying the extreme red ray from *A* to *R*, the extreme orange from *A* to *O*, the extreme yellow from *A* to *Y*, &c., and will form the usual prismatic spectrum *ROYGBPVC*. If the whole length *RC* be divided into 1000 parts, we shall have (when the whole refraction *AR* is small), *RO* very nearly 125, *RY* = 200, *RG* = 333, *RB* = 500, *RP* = 667, *RV* = 778, and *RC* = 1000; this being the proportion observed in the differences of the sines of refraction by Sir Isaac Newton. Dr. Blair has found that certain fluids, particularly such as contain the muriatic acid, when formed into a prism, will refract the light from *H'* (in the lower line) so as to form a spectrum *R'C'* equal to *RC*, and as far removed from *A''* as *RC* is from *A*, but having the colors more dilated toward *R''*, and more constipated toward *C*, than is observed in *RC*; so that the ray which was carried by the prism of common glass to the middle point *B''* considerably nearer to *C''*. Let us now suppose that instead of a white spot at *A*, we have a prismatic spectrum *AB* fig. 7, and that the prism of common glass is applied as before, immediately behind the prism which forms the spectrum *AB*. We know that this will be refracted sidewise, and will make a spectrum *ROYGBPC*, inclined to the plane of refraction in an angle of 45°; so that drawing the perpendicular *RC'* we have *RC' = CC*. We also know that the prism of flint glass would refract the spectrum formed by the first prism on *EHF*, in such a manner that the red ray will go to *R*, the violet to *C*, and the intermediate rays to points *o, y, g, b, p, v*, so situated that *O'o* is = *R'O'* of the other figure: *Yy* is = *R'Y'*, &c. These points must therefore lie in a curve *RoypbvC*, which is convex toward the axis *R'C'*. In like manner we may be assured that Dr. Blair's fluid will form a spectrum *R'o'y'g'b'p'v'C'*, concave towards *R'C'*. This is a very good method for discovering whether a medium disperses the light in the same proportion with the prism which is employed for forming the first spectrum *AB* or *EF*. It disperses in the same or in a different proportion, according as the oblique spectrum is straight or crooked; and the exact proportion corresponding to each color is had by measuring the ordinates of the curves *RbC'* or *Rb'C'*. Having formed the oblique spectrum *RBC* by a prism of common glass

an equal prism of the same glass, placed in a contrary position, will bring back all the rays from the spectrum RBC to the spectrum AB, laying each color on its former place. In like manner, having formed the oblique spectrum RBC by a prism of flint-glass, we know that another prism of flint-glass, placed in the opposite direction, will bring all the rays back to the spectrum EHF. But having formed the oblique spectrum RBC by a prism in common glass, if we place the flint-glass prism in the contrary position, it will bring the color R back to E, and the color C to F; but it will not bring the color B to H, but to a point h , such that Bh is equal to bH , and bB to hH . In like manner, the other colors will not be brought back to the straight line EHF, but to a curve EhF , forming a crooked spectrum. In like manner the fluids discovered by Dr. Blair when employed to bring back the oblique spectrum RBC, formed by common glass, will bring its extremities back to E and F, and form the crooked spectrum EhF lying beyond EHF. This experiment evidently gives us another method for examining the proportionality of the dispersion of different substances. Having by common glass brought back the oblique spectrum formed by common glass to its natural place AB, suppose the original spectrum at AB to contract gradually (as Newton has made it to do by means of a lens), it is plain that the oblique spectrum will also contract, and so will the second spectrum at AB; and it will at last coalesce into a white spot. The effect will be equivalent to a gradual compression of the whole figure, by which the parallel lines AR and BC gradually approach, and at last unite. In like manner when the oblique spectrum formed by flint-glass is brought back to EHF by a flint-glass prism, and the figure compressed in the same gradual manner, all the colors will coalesce into a white spot. But when flint-glass is employed to bring back the oblique spectrum formed by common glass, it forms the crooked spectrum EhF . Now let the figure be compressed. The curve EhF will be doubled down on the line Hh , and there will be formed a compound spectrum Hh , quite unlike the common spectrum, being purple or claret colored at H by the mixture of the extreme red and violet, and green edged with blue at h by the mixture of the green and blue. The fluid prisms would in like manner form a spectrum of the same kind on the other side of H. This is precisely what is observed in achromatic object-glasses made of crown glass and flint; for the refraction from A to R corresponds to the refraction of the convex crown-glass; and the contrary refraction from R to E corresponds to the contrary refraction of the concave flint-glass, which still leaves a part of the first refraction, producing a convergence to the axis of the telescope. It is found to give a purple or wine-colored focus, and within this a green one, and between these an imperfect white. Dr. Blair found that, when the eye-glass was drawn out beyond its proper distance, a star was surrounded by a green fringe, by the green end of the spectrum, which crossed each other within the focus; and, when the eye-

glass was too near the object-glass, the star had a wine-colored fringe. The green rays were ultimately most refracted. Dr. Blair very properly calls these spectrums Hh and Hh secondary spectrums, and seems to think that he is the first who has taken notice of them. But Mr. Clairault was too accurate a mathematician, and too careful an observer, not to be aware of a circumstance which was of primary consequence to the whole enquiry. He could not but observe that the success rested on this very particular, and that the proportionality of dispersion was indispensably necessary. This subject was touched on by Clairault; and fully discussed by Boscovich, first in his Dissertations, published at Vienna in 1759; then in the Comment. Bolognensis; and, lastly, in his Opuscula, 1785. Dr. Blair read an ingenious Dissertation on Achromatic Glasses to the Royal Society of Edinburgh in 1793. Boscovich shows how to unite the two extremes with the most outstanding color of the secondary spectrum, by means of a third substance. When we have done this, the aberration occasioned by the secondary spectrums must be prodigiously diminished; for it is evidently equivalent to the union of the points H and h of our figure. Whatever cause produces this, must diminish the curvature of the arches Eh and hF ; but, even if these curvatures were not diminished, their greatest ordinates cannot exceed one-fourth of Hh ; and we may say, without hesitation, that, by uniting the mean or most outstanding ray with the two extremes, the remaining dispersion will be as much less than the uncorrected color of Dolland's achromatic glass, as this is less than four times the dispersion of a common object-glass. It must therefore be altogether insensible. Boscovich asserts, that it is not possible to unite more than two colors by the opposite refraction of two substances, which do not disperse the light in the same proportions. Dr. Blair makes light of this assertion, as he finds it made in general terms in the extract made by Priestly from Boscovich in his Essay on the History of Optics; but, had he read this author in his own dissertations, he would have seen that he was perfectly right. Dr. Blair, however, hit on a very ingenious and effectual method of producing this union of three colors. In the same way as we correct the dispersion of a concave lens of crown-glass by the opposite dispersion of a concave lens of flint-glass, we may correct the secondary dispersion of an achromatic convex lens by the opposite secondary dispersion of an achromatic concave lens. But this union does not contradict the assertion of Boscovich, because it is necessarily produced by means of three refracting substances. The most essential service which the public has received from Dr. Blair is the discovery of fluid mediums of a dispersive power. By composing the lenses of such substances we are at once freed from the irregularities, in the refraction and dispersion of flint glass, which the chemists have not been able to free it from. In whatever way this glass is made, it consists of parts which differ both in refractive and dispersive power; and when taken up from the pot these parts mix in threads,

which may be disseminated through the mass in any degree of fineness. But they still retain their properties; and, when a piece of flint glass has been formed into a lens, the eye, placed in its focus, sees the whole surface occupied by glistening threads or broader veins running across it. Great rewards have been offered for removing this defect, but hitherto to no purpose. We would propose the following method:—Let the glass be reduced to powder, and then melted with a great proportion of alkaline salt, so as to make a liquor silicum. When precipitated from this by an acid, it must be in a state of very uniform composition. If again melted into glass we should hope that it would be free from this defect; if not, the case seems to be desperate. But by using a fluid medium Dr. Blair was free from all this embarrassment; and he acquired another immense advantage, that of adjusting at pleasure both the refractive and dispersive powers of his lenses. In solid lenses we do not know whether we have taken the curvatures suited to the refractions till our glass is finished; and, if we have mistaken the proportions, all our labor is lost. But when fluids are used it is enough that we know nearly the refractions. We suit our focal distances to these, and then select our curvatures, so as to remove the aberration of figure, preserving the focal distances. Thus, by properly tempering the fluid mediums, we bring the lens to agree precisely with the theory, perfectly achromatic and the aberration of figures as much corrected as is possible. Dr. Blair examined the refractive and dispersive powers of a great variety of substances, and found great varieties in their actions on the different colors. This was indeed to be expected. There is no doubt now among naturalists about the mechanical connexion of the phenomena of nature; and all agree that the chemical actions of the particles of matter are perfectly like in kind to the action of gravitating bodies; that all these phenomena are the effects of forces like those which we call attractions and repulsions, and which we observe in magnets and electrified bodies; that light is refracted by forces of the same kind, but differing chiefly in the small extent of their sphere of activity. One who views things in this way will expect that as the actions of the same acid for the different alkalis are different in degree, and as the different acids have also different actions on the same alkali, in like manner different substances differ in their general refractive powers, and also in the proportion of their action on the different colors. Nothing is more unlikely, therefore, than the proportional dispersion of the different colors by different substances. Common glass disperses the rays in such a manner that the ray which is in the cosine of the green and blue occupies the middle of the prismatic spectrum; but in glasses, and many other substances which are more dispersive, this ray is nearer to the ruddy extremity of the spectrum. While, therefore, the straight line RC' , fig. 7, terminates the ordinates Oo' , YY' , Gg' , &c., which represent the dispersion of common glass, the ordinates which express the dispersions of these substances are terminated by a curve passing through R and C' , but lying

below the line RC' . When, therefore, parallel heterogeneous light is made to converge to the axis of a convex lens of common glass, as happens at F in fig. 5, C , the light is dispersed, and the violet rays have a shorter focal distance. If we now apply a concave lens of greater dispersive power, the red and violet rays are brought to one focus F' ; but the green rays, not being so much refracted away from F , are left behind at ϕ , and have now a shorter focal distance. But Dr. Blair afterwards found that this was not the case with the muriatic acid, and some solutions in it. He found that the ray which common glass caused to occupy the middle of the spectrum was much nearer to the blue extremity when refracted by these fluids. Therefore a concave lens formed of such fluids which united the red and violet rays in F' refracted the green rays to f . Having observed this, it was an obvious conjecture that a mixture of some of these fluids might produce a medium, whose action on the intermediate rays should have the same proportion that is observed in common glass; or that two of them might be found which formed spectra similarly divided, and yet differing sufficiently in dispersive power to enable us to destroy the dispersion by contrary refractions, without destroying the whole refraction. Dr. Blair accordingly found a mixture of solutions of ammoniacal and mercurial salts, and also some other substances which produced dispersions proportional to that of glass, with respect to the different colors. We have examined one of his telescopes: the focal distance of the object-glass did not exceed seventeen inches, and the aperture was fully three inches and a half. We viewed some single and double stars and some common objects with this telescope, and found that in magnifying power, brightness, and distinctness, it was manifestly superior to one of Mr. Dollond's of forty-two inches focal length. It also gave us an opportunity of admiring the dexterity of the London artists, who could work the glasses with such accuracy. We had most distinct vision of a star when using an erecting eye-piece, which made this telescope magnify more than 100 times; and we found the field of vision as uniformly distinct as with Dollond's forty-two inch telescope magnifying forty-six times. The intelligent reader must admire the nice figuring and centering of the very deep eye-glasses which are necessary for this amplification.

Methods of constructing and correcting the eye-glasses.—The proper construction of an eye-piece is not less essential than that of the object-glass. But our limits will not allow us to treat this subject in the same detail, having already extended this article to a great length. Our readers will find abundant information in Dr. Smith's Optics concerning the eye-glasses, chiefly deduced from Huyghens's fine theory of aberration. At the same time we must again pay Mr. Dollond the merited compliment of saying, that he was the first who made any scientific application of this theory to the compound eye-piece for erecting the object. His eye-pieces of five and six glasses are very ingenious reduplications of Huyghens's eye-piece of two glasses, and would probably have superseded all others had not his

discovery of achromatic object-glasses caused opticians to consider the chromatic dispersion with more attention, and pointed out methods of correcting it in the eye-piece without any compound eye-glasses. They have found that this may be more conveniently done with four eye-glasses, without sensibly diminishing the advantages which Huyghens showed to be the result from employing many small refractions instead of a lesser number of great ones. As this is a very curious subject, we shall endeavour to make our readers fully acquainted with it, and content ourselves with merely mentioning the principles of the other rules for constructing an eye-piece. If $A B$, fig. 8, plate I, be a lens, R a radiant point of focus of incident rays, and a the focus of parallel rays coming from the opposite side; then, 1. Draw the perpendicular aa' to the axis, meeting the incident ray in a' , and $a'A$ to the centre of the lens. The refracted ray BF is parallel to $a'A$; for $Ra' : a'A (= Ra : aA) = RB : BF (= RA : AF)$, which is the focal theorem. 2. An oblique pencil BPb , proceeding from any point P , which is not in the axis, is collected to the point f , where the refracted ray BF cuts the line PAf drawn from P through the centre of the lens; for $Pa' : a'A = PB : Bf$, which is also the focal theorem.

The principle of the common astronomical telescope may now be exhibited. See fig. 9. The beam of parallel rays, inclining to the axis, is made to converge to a point G , where it forms an image of the lowest point of a very distant object. These rays, decussating from G , fall on the eye-glass; the ray from the lowest point B of the object-glass falls on the eye-glass at b ; and the ray from A falls on a ; and the ray from the centre O falls on o . These rays are rendered parallel, or nearly so, by refraction through the eye-glass, and take the direction bi, oi, ai . If the eye be placed so that this pencil of parallel rays may enter it, they converge to a point of the retina, and give distinct vision of the lowest point of the object. It appears inverted, because the rays by which we see its lowest point come in the direction which in simple vision is connected with the upper point of an object. They come from above, and therefore are thought to proceed from above. We see the point as if situated in the direction Io . In like manner the eye placed at I sees the upper point of the object in the direction IP , and its middle in the direction IE . The proper place for the eye is I : if brought much nearer the glass, or removed much farther from it, some, or the whole, of this extreme pencil of rays will not enter the pupil. It is therefore of importance to determine this point. Because the eye requires parallel rays for distinct vision, it is plain that F must be the principal focus of the eye-glass. Therefore, by the common focal theorem, $OF : OE = OE : OI$ or $OF : FE = OE : EI$. The magnifying power being measured by the magnitude of the visual angle, compared with the magnitude of the visual angle with the naked eye, we have $\frac{oIp}{oP}$ or $\frac{oIf}{oF}$, for the measure of the magnifying power. This is very nearly $= \frac{OE}{EI}$, or $\frac{OF}{FI}$. As

the line OE , joining the centres of the lenses, and perpendicular to their surfaces, is called the axis of the telescope, so the ray OG is called the axis of the oblique pencil, being really the axis of the cone of light which has the object-glass for its base. This ray is through its whole course the axis of the oblique pencil; and, when its course is determined, the amplification, the field of vision, the apertures of the glasses, are all determined. For this purpose we have only to consider the centre of the object-glass as a radical point, and trace the process of a ray from this point through the other glasses; this will be the axis of some oblique pencil. It is evident, therefore, that the field of vision depends on the breadth of the eye-glass. Should we increase this, the extreme pencil will pass through I , because O and I are still the conjugate foci of the eye-glass. On the other hand the angle resolved on for the extent of field of vision gives the breadth of the eye-glass. For all optical instruments there must be two optical figures considered. The first shows the progress of a pencil of rays coming from one point of the object. The various focuses of this pencil show the places of the different images, real or virtual. Such a figure is formed by the three rays AGa , $OGoi$, $BGbi$. The second shows the progress of the axis of the different pencils proceeding through the centre of the object-glass. The focuses of this pencil of axes show the places where an image of the object-glass is formed; and this pencil determines the field of vision, the apertures of the lenses, and the application or magnifying power. The three rays $OGoi$, $OFEl$, $OHPI$, form this figure. See also fig. 14, where the progress of both sets of pencils is more diversified. The perfection of a telescope is to represent an object in its proper shape, distinctly magnified, with a great field of vision, and sufficiently bright. But there are limits to all these qualities; and an increase of one of them, for the most part, diminishes the rest. The brightness depends on the aperture of the object-glass, and will increase in the same proportion, because i' will always be to AB in the proportion of EF to FO , till the diameter of the emergent pencil is equal to that of the pupil of the eye. Increasing the object-glass any more, can send no more light into the eye. But we cannot make the emergent pencil nearly so large as this when the telescope magnifies much; for the great aperture of the object-glass produces an indistinct image at GF , and its indistinctness is magnified by the eye-glass. A great field of vision is incompatible with the true shape of the object; for since the angles of the marginal parts are enlarged by the aberration of the eye-glass, the marginal parts themselves will appear enlarged, or the object appear distorted. Thus a chess board, viewed through a reading glass, appears drawn out at the corners, and the straight lines are all changed into curves. The circumstance which most peremptorily limits the extent of field is the necessary distinctness. If the vision be indistinct, it is useless, and no other quality can compensate this defect. The distortion is very inconsiderable in much larger angles of vision than we can admit, and it is unworthy of the attention paid to it by optical writers. They

have been induced to take notice of it, because the means of correcting it, in a considerable degree, are attainable, and afford an opportunity of exhibiting their knowledge; whereas the indistinctness which accompanies a large field is a subject of most difficult discussion, and has hitherto baffled all their efforts to express by any intelligent or manageable formulæ. This subject must, however, be considered. The image at GF , fig. 9, of a very moderate object, is not a plain surface perpendicular to the axis of the telescope, but is nearly spherical, having O for its centre. If a number of pencils of parallel rays crossing each other in I fall on the eye-glass, they will form a picture on the opposite side, in the focus F . But this picture will by no means be flat, nor nearly so, but very concave towards E . Its exact form is of most difficult investigation. The elements of it are given by Dr. Barrow. Therefore it is impossible that the picture formed by the object-glass can be seen distinctly in all its parts by the eye-glass. Even if it were flat, the points G and H , fig. 9, are too far from the eye-glass when the middle F is at the proper distance for distinct vision. When, therefore, the telescope is so adjusted that we have distinct vision of the middle of the field, in order to see the margin distinctly we must push in the eye-glass; and, having so done, the middle of the field becomes indistinct. When the field of vision exceeds 12° or 15° , it is not possible by any contrivance to make it tolerably distinct all over; and we must turn the telescope successively to the different parts of the field that we may see them agreeably. The cause of this indistinctness is the shortness of the lateral foci of lateral and oblique pencils refracted by the eye-glass. But the determination is not complete, and relates only to those rays which are in a plane passing through the axis of the lens. But the oblique pencil bGa , fig. 9, by which an eye placed at I sees the point G of the image, is a cone of light having a circular base on the eye-glass, of which circle ab is one of the diameters. There is a diameter perpendicular to this, which, in this figure, is represented by the point a . Figs. 10 and 11, represents the base of the cone as seen by an eye placed in the axis of the telescope, with the object-glass as appearing behind it. The point b is formed by a ray which comes from the lowest point B of the object-glass, and the point a is illuminated by a ray from A . The point c at the right hand of the circular base of this cone of light came from the point C on the left side of the object glass; and the light comes to d from D . Now the laws of optics demonstrate that the rays which come through the points c and d are more convergent after refraction than the rays which come through a and b . The analogies, therefore, which ascertain the foci of rays lying in planes passing through the axis do not determine the foci of the others. Of this we may be sensible by looking through a lens to a figure on which are drawn concentric circles crossed by radii. When the telescope is so adjusted that we see distinctly the extremity of one of the radii, we shall not see distinctly the circumference which crosses the extremity with equal distinctness, and vice versâ. This differ-

ence, however, between the foci of the rays which come through a and b , and those which come through c and d , is not considerable in the fields of vision which are otherwise admissible. But the same difference of foci obtains also with respect to the dispersion of light, and is more remarkable. Both d'Alembert and Euler have attempted to introduce it into their formulæ; but they have made them useless for any practical purpose by their inextricable complication. This must serve as a general indication of the difficulties which occur in the construction of telescopes, even although the object-glass were perfect, forming an image without the smallest confusion or distortion. There is yet another difficulty. The rays of the pencil aGb , fig. 9, when refracted through the eye-glass, are also separated into their component colors. The edge of the lens must evidently perform the office of a prism, and the white ray Gb will be so dispersed that, if $b'i$ be the path of its red ray, the violet ray, which makes another part of it, will take such a course bn that the angle $i'bn$ will be nearly one-twenty-seventh of $Gb'i'$. The ray Ga , passing through a part of the lens whose surfaces are less inclined to each other, will be less refracted, and will be less dispersed in the same proportion very nearly; therefore the two violet rays will be very nearly parallel when the two red rays are rendered parallel. Hence it must happen that the object will appear bordered with colored fringes. A black line, seen near the margin on a white ground, will have a ruddy and orange border on the outside, and a blue border within; and this confusion is altogether independent on the object-glass, and is so much the greater as the visual angle bIE is greater. Such are the difficulties; they would be insurmountable were it not that some of them are so connected that, to a certain extent, the diminution of one is accompanied by a diminution of the other. The point G is very nearly in the caustic formed by a beam of light consisting of rays parallel to Io , and occupying the whole surface of the eye-glass, because the pencil of rays which are collected at G is very small. Any thing therefore that diminishes the mutual inclination of the adjoining rays puts their concourse farther off. Now this is precisely what we want; for the point G of the image formed by the object-glass is already beyond the focus of the oblique slender pencil of parallel rays ia and $i'b$; and therefore, if we could make this focus go a little farther from a and b , we shall bring it nearer to G , and obtain more distinct vision of this point of the object. Now let it be recollected that, in moderate refractions through prisms, two rays which are inclined to each other in a small angle are, after refraction, inclined to each other in the same angle; therefore, if we can diminish the aberration of the ray ai or oI , or $b'i'$, we diminish their mutual inclination, and consequently the mutual inclination of the rays Ga , Ga , Gb , and therefore lengthen the focus, and get more distinct vision of the point G . Therefore we at once correct the distortion and the indistinctness; and this is the aim of Mr. Huyghens's great principle of dividing the refractions. The general method is as follows:—Let o be the object-glass

(fig. 12) and E the eye-glass of a telescope, and F their common focus, and FG the image formed by the object-glass. The proportion of their focal distances is supposed to be such as gives as great a magnifying power as the perfection of the object-glass will admit. Let BI be the axis of the emergent pencil. It is known by focal theorem that GE is parallel to BI; therefore BGE is the whole refraction or deflection of the ray OHB from its former direction. Let us diminish the aberrations by dividing this into two parts by means of two glasses D and e, so as to make the ultimate angle of vision *bie* equal to BIE, and thus retain the same magnifying power and visible field. Let us divide it into the parts BGC and CGE. From G draw any line GD to the axis towards O; and draw the perpendicular DH, cutting OG in H; draw Hc parallel to GC, cutting GD in g; draw *gf* perpendicular to the axis, and *ge* parallel to GE; draw *eb* perpendicular to the axis; draw Dδ parallel to GC, and δd perpendicular to the axis. Then if there be placed at D a lens whose focal distance is Dd, and another at e whose focal distance is ef, the thing is done. The ray OH will be refracted into Hb, and this into bi parallel to BI. The demonstration of this construction is so evident, by means of the common focal theorem, that we need not repeat it. We have the same magnifying power, and the same field of vision; we have less aberration, and therefore less distortion and indistinctness; and this is brought about by a lens HD of a smaller aperture and a greater focal distance than BE. Consequently, if we are contented with the distinctness of the margin of the field with a single eye-glass, we may greatly increase the field of vision; for if we increase DH to the size of EB we shall have a greater field, and much greater distinctness in the margin; because HD is of a longer focal distance, and will bear a greater aperture, preserving the same distinctness at the edge. On this account the glass HD is commonly called the field-glass. It must be observed here, however, that although the distortion of the object is lessened, there is a real distortion produced in the image *fg*. But this, when magnified by the glass e, is smaller than the distortion produced by the glass E, of greater aperture and shorter focus, on the undistorted image GF. But, because there is a distortion in the second image *fg*, this construction cannot be used for the telescopes of astronomical quadrants, and other graduated instruments, because then equal divisions of the micrometer would not correspond to equal angles. But the same construction will answer in this case, by taking the point D on that side of F which is remote from O (fig. 13). This is the form now employed in the telescopes of all graduated instruments. The great refractions which take place on the eye-glasses occasion very considerable dispersions, and disturb the vision by fringing every thing with colors. To remedy this, achromatic eye-glasses may be employed, constructed by the rules already delivered. This construction, however, is incomparably more intricate than that of object-glasses; for the equations must involve the distance of the radiant point, and be more

complicated; and this complication is immensely increased on account of the great obliquity of the pencils. Fortunately the Huyghenian construction of an eye-piece enables us to correct this dispersion to a great degree of exactness. By it we may free the eye-glasses from the greatest part of the effect of dispersion. We may do it entirely by pushing the eye-glass a little nearer to the field-glass. This will render the violet rays a little divergent from the red, so as to produce a perfect picture from the bottom of the eye. But by doing so we have hurt the distinctness of the whole picture. We remedy this by drawing both glasses out a little, and the telescope is made perfect.

Presuming that the reader is now pretty familiar with the different circumstances which must be considered in the construction of an eye-piece, we proceed to consider those which must be employed to erect the object. This may be done by placing the lens which receives the light from the object-glass in such a manner that a second image (inverted with respect to the first) may be formed beyond it, and this may be viewed by an eye-glass. But, besides many other defects, it tinges the object prodigiously with color. But the common day telescope, invented by F. Rheita, has, in this respect, greatly the advantage of the above. This telescope may be improved by substituting for the eye-glass *ik* (fig. 7) the Huyghenian double eye-glass, or field-glass and eye-glass, figs. 12 and 13; and the first of these may be improved and rendered achromatic. This will require the two glasses *af* and *gh* to be increased from their present dimensions to the size of a field-glass, suited to the magnifying power of the telescope, supposing it an astronomical telescope. Thus we shall have a telescope of four eye-glasses. The first three will be of a considerable focal distance, and two of them will have a common focus. But this is considerably different from the eye-piece of four glasses which are now used, and are far better. We are indebted for them to Mr. Dollond, who was a mathematician as well as an artist, and in the course of his research discovered resources which had not been thought of. He had not then discovered the achromatic object-glass, and was busy in improving the eye-glasses by diminishing their spherical aberration. His first thought was to make the Huyghenian addition at both the images of the day telescope. This suggested to him the following eye-piece of five glasses. Fig. 14 represents this eye-piece, but there is not room for the object-glass at its proper distance. A pencil of rays coming from the upper point of the object is made to converge (by the object-glass) to G, where it would form a picture of that part of the object. But it is intercepted by the lens Aa, and its axis is bent towards the axis of the telescope in the direction *ab*. At the same time the rays which converged to G converge to *g*, and there is formed an inverted picture of the object at *gf*. The axis of the pencil is again refracted at *b*, crosses the axis of the telescope in H, is refracted again at *c*, at *d*, and at *e*, and at last crosses the axis in I. The rays of this pencil, diverging from *g*, are made less diverging, and proceed as if they came from

g' , in the line Bgg' . The lens cC causes them to converge to g' , in the line $G'Cg'$. The lens dD makes them converge still more to G' , and there they form an erect picture $G''F''$; diverging from G'' , they are rendered parallel by the refraction at e . At H the rays are nearly parallel. Had the glass Bb been a little farther from A , they would have been accurately so, and the object-glass, with the glasses A and B , would have formed an astronomical telescope with the Huyghenian eye-piece. The glasses C, D , and E , are intended merely for bending the rays back again till they again cross the axis in I . The glass C tends chiefly to diminish the great angle $BIIb$; and then the two glasses D and E are another Huyghenian eye-piece. The art in this construction lies in the proper adjustment of the glasses, so as to divide the whole bending of the pencil pretty equally among them, and to form the last image in the focus of the eye-glass, and at a proper distance from the other glass. Bringing B nearer to A would bend the pencil more to the axis. Placing C farther from B would do the same thing; but this would be accompanied with more aberration, because the rays would fall at a greater distance from the centres of the lenses. The greatest bending is made at the field-glass D ; and we imagine that the telescope would be improved, and more distinct at the edges of the field, by employing another glass of great focal distance between C and D . There is an image formed at II of the object-glasses, and the whole light passes through a small circle in this place. It is usual to put a plate here pierced with a hole which has the diameter of this image. A second image of the object-glass is formed at I , and indeed wherever the pencils cross the axis. A lens placed at II makes no change in any of the angles, nor in the magnifying power, and affects only the place where the images are formed. And, on the other hand, a lens placed at f , or F'' , where a real image is formed, makes no change in the places of the images, but affects the mutual inclination of the pencils. This affords a resource to the artist, by which he may combine properties which seem incompatible. The aperture of A determines the visible field and all the other apertures. We must avoid forming a real image, such as fg , or $F''G''$, on or very near any glass. For we cannot see this image, without seeing along with it every particle of dust and every scratch on the glass. We see them as making part of the object when the image is exactly on the glass, and we see them confusedly, and so as to confuse the object, when the image is near it. For, when the image is on or very near any glass, the pencil of light occupies a very small part of its surface, and a particle of dust intercepts a great proportion of it. This construction will not do for the telescope of graduated instruments, because the micrometer cannot be applied to the second image fg , on account of its being a little distorted. Also the interposition of the glass C makes it difficult to correct the dispersion. By proper reasoning from the correction in the Huyghenian eye-piece, we are led to the best construction of one with three glasses. Let $P'A$ (fig. 15) be the glass

which first receives the light proceeding from the image formed by the object-glass, and let OP be the axis of the extreme pencil. This is refracted into PR , which is again refracted into Rr by the next lens B . Let b be the focus of parallel rays of the second lens. Draw PBr . We know that $Ab : bB = PB : Br$, and that rays of one kind diverging from P will be collected at r . But if PR, PV , be a red and a violet ray, the violet ray will be more refracted at V , and will cross the red ray in some intermediate point g of the line Rr . If therefore the first image had been formed precisely on the lens PA , we should have a second image at $f'g$ free from all colored fringes. If the refractions at P and R are equal (as in the common day telescope), the dispersion at V must be equal to that at P , or the angle $vVr = VPR$. But we have ultimately $RPV : RrV = BC : AB (= Bb : Ab$ by the focal theorem); therefore $gVr : grV$ (or $gr : gV$, or $Cf : fB = Bb : Ab$, and $AB : Ab = Rr : Rg$. This shows the advantage of the common day telescope. In this $AB = 2Ab$, and therefore f' is the place of the last image which is free from colored fringes. But this image will not be seen free from colored fringes through the eye-glass Cr , if f' be its focus; for had gr, gv , been both red rays, they would have been parallel after refraction; but gv , being a violet ray, will be more refracted. It will not indeed be so much deflected from parallelism as the violet ray, which naturally accompanies the red ray to r , because it falls nearer the centre. By computation its dispersion is diminished about one-seventh. That gv may be made parallel to gr , after refraction, the refraction at r must be such that the dispersion corresponding to it may be of a proper magnitude. Let the dispersion at g be to the dispersion produced by the refraction at r (which is required for producing the intended magnifying power) as 1 to 9. Make $9 : 1 = f'f' : f'C = f'C : CD$, and draw the perpendicular $D'r'$ meeting the refracted rr' in r' . Then we know, by the common focal theorem, that if f' be the focus of the lens Cr , red rays diverging from g will be united in r' . But the violet ray gv will be refracted into $v'v'$ parallel to rr' . For the angle $v'r' : vgr =$ (ultimately) $f'C : CD = 9 : 1$. Therefore the angle $v'r'$ is equal to the dispersion produced at r , and therefore equal to $r'v'$, and $v'v'$ is parallel to rr' . But by this we have destroyed the distinct vision of the image formed at $f'g$, because it is no longer at the focus of the eye-glass. But distinct vision will be restored by pushing the glasses nearer to the object-glass. This makes the rays of each particular pencil more divergent after refraction through A , but scarcely makes any change in the directions of the pencils themselves. Thus the image comes to the focus f' , and makes no sensible change in the dispersions. In the common day telescope, the first image is formed in the anterior focus of the first eye-glass, and the second image is at the anterior focus of the last eye-glass. If we change this last for one of half the focal distance, and push in the eye-piece till the image formed by the object-glass is half way between the first eye-glass and its focus, the last image will be formed at the focus of the new

eye-glass, and the eye-piece will be achromatic. This is easily seen by making the usual computations by the focal theorem. But the visible field is diminished, because we cannot give the same aperture as before to the new eye-glass; but we can substitute for it two eye-glasses, like the former, placed close together. This will have the same focal distance with the new one, and will allow the same aperture that we had before. On these principles may be demonstrated the correction of color in eye-pieces with three glasses of the following construction. Let the glasses A and B be placed so that the posterior focus of the first nearly coincides with the anterior focus of the second, or rather so that the anterior focus of B may be at the place where the image of the object-glass is formed, by which situation the aperture necessary for transmitting the whole light will be the smallest possible. Place the third, C, at a distance from the second, which exceeds the sum of their focal distances by a space which is a third proportional to the distance of the first and second, and the focal distance of the second. The distance of the first eye-glass from the object-glass must be equal to the product of the focal distance of the first and second divided by their sum. Let Oo, Aa, Bb, Cc , the focal distances of the glasses, be O, a, b, c . Then make $\Lambda B = a + b$ nearly; $BC = b + c + \frac{b^2}{b+c}$; $OA = \frac{bc}{b+c}$. The amplifying or magnifying power will be $= \frac{ob}{ac}$; the equivalent eye-

glass $= \frac{ac}{b}$; and the field of vision $= 3438' \times \frac{\text{Aperture of A}}{\text{foc. dist. ob. gl.}}$. These eye-pieces will admit the use of a micrometer at the place of the first image, because it has no distortion.

Mr. Dollond was anxious to combine this achromatism of the eye-pieces with the advantages which he had found in the eye-pieces with five glasses. This eye-piece of three glasses necessarily has a very great refraction at the glass B, where the pencil which has come from the other side of the axis must be rendered again convergent, or at least parallel to it. This occasions considerable aberrations. This may be avoided by giving part of this refraction to a glass put between the first and second, in the same way as he has done by the glass B put between A and C in his five glass eye-piece. But this deranges the whole process. His ingenuity, however, surmounted this difficulty, and he made eye-pieces of four glasses, which seem as perfect as can be desired. If we make the rays of different colors unite on the surface of the field-glass, the thing will be done, because the dispersion from this point of union will then unite with the dispersion produced by this glass alone; and this increased dispersion may be corrected by the last eye-glass in the way already shown. Therefore let A, B (fig. 16, plate I.), be the stations which we have fixed on for the first and second eye-glasses, in order to give a proper portion of the whole refraction to the second glass. Let b be the anterior focus of B. Draw PBr through the centre of B. Make $A b$

$: b B = \Lambda B : BK$. Draw the perpendicular Kr , meeting the refracted ray in r . By the focal theorem, red rays diverging from P will converge to r ; but the violet ray PV , being more refracted, will cross Rr in some point g . Drawing the perpendicular fg , we get f for the proper place of the field-glass. Let the refracted ray Rr , produced backwards, meet the ray OP coming from the centre of the object-glass in O . Let the angle of dispersion RPV be called p , and the angle of dispersion at V , that is rVv , be v , and the angle VrR be r . It is evident that $OR : OP = p : v$, because the dispersions are proportional to the sines of the refractions, which, in this case, are very nearly as the refractions themselves. Let $\frac{OP}{OR}$ (or $\frac{op}{pB}$ or $\frac{pB}{bB}$) be made $= m$. Then $v = mp$; also $p : r = BK : AB = bB : Ab$, and $r = p \cdot \frac{Ab}{bB}$ or, making $\frac{\Lambda b}{Bb} = n, r = np$;

therefore $v : r = m : n, = \frac{pB}{bB} : \frac{\Lambda b}{Bb} = pB : \frac{\Lambda b}{Bb}$. The angle $RgV = gVr + grV = p \cdot \frac{m}{m+n}$; and $RgV : Rrv = Rr : Rg$, or $m + n : n = Rr : Rg$, and $Rg = Rr \cdot \frac{n}{m+n}$. But Rr is ultimately $= BK = AB \cdot \frac{bB}{Ab} = \frac{\Lambda B}{n}$.

Therefore $Rg = \frac{\Lambda B}{n} \times \frac{n}{m+n} = \frac{\Lambda B}{m+n}$, and $Bf = \frac{\Lambda B}{m+n}$. This value of Bf is evidently

$= bB \times \frac{\Lambda B}{pB + \Lambda b}$. Now bB being a constant quantity, while the glass B is the same, the place of union varies with $\frac{\Lambda B}{pB + \Lambda b}$. If we remove B a little farther from A, we increase ΛB , and pB , and Λb , each by the same quantity. This evidently diminishes Bf . On the other hand, bringing B nearer to A increases Bf . If we keep the distance between the glasses the same, but increase the focal distance bB , we augment Bf , because this change augments the numerator and diminishes the denominator of the fraction $\frac{bB \times \Lambda B}{pB + \Lambda b}$.

Thus we can unite the colors at what distance we please, and consequently in the place of the intended field-glass, from which they will diverge with an increased dispersion, viz. with the dispersion competent to the refraction produced there, and the dispersion $p \times m + n$ conjoined. It only remains to determine the proper focal distances of the field-glass and eye-glass, and the place of the eye-glass, so that this dispersion may be finally corrected. This is an indeterminate problem, admitting of an infinity of solutions. We shall limit it by an equal division of the two remaining refractions, which are necessary to produce the intended magnifying power. This construction has the advantage of diminishing the aberration. Thus we know the two refractions, and the dispersion competent to each; it being nearly one-twenty-seventh of the refraction.

Call this q . The whole dispersion at the field-glass consists of g , and of the angle KgV of fig. 16 which we also know to be $= p \times m + n$. Call their sum s . Let fig. 17 represent this addition to the eye-piece. Cg is the field-glass coming in the place of $f'g$ of fig. 19, and Rgw is the red ray coming from the glass BR . Draw gs parallel to the intended emergent pencil from the eye-glass; that is, making the angle Csg with the axis correspond to the intended magnifying power. Bisect this angle by the line gK . Make $sg : gq = s : q$, and draw qK , cutting Cg in t . Draw $t\delta D$, cutting gk in δ , and the axis in D . Draw δd and $D\tau$ perpendicular to the axis. Then a lens placed in D , having the focal distance Dd , will destroy the dispersion at the lens gC , which refracts the ray gw into gr . Let gv be the violet ray, making the angle $vgv = s$. By the common optical theorem, gr will be refracted into rr' parallel to δD . Draw $gD\tau'$ red rays $grgv$, will be united in r' . But the violet ray gv will be more refracted, and will take the path $v'v'$, making the angle of dispersion $r'v'v' = q$, very nearly, because the dispersion at v does not sensibly differ from that at r . Now, in the small angles of refraction which obtain in optical instruments, the angles $r'v', rgv$, are very nearly as gr and rr' , or as gD and $D\tau'$, or as CD and DT ; which, by the focal theorem, are as Cd and dD ; that is, $Dd : dc = rgv : rr'v$. But $Dd : dc = D\delta : \delta t = sg : gq = s : q$. But $rgv = s$; therefore $rr'v = q = r'v'v'$, and $v'v'$ is parallel to rr' , and the whole dispersion at g is corrected by the lens $D\tau$. The focal distance Cc of Cg is had by drawing $C\kappa$ parallel to Kg , meeting Rg in κ , and drawing κc perpendicular to the axis. It is easy to see that this elegant construction is not limited to the equality of the refractions wgr, Krr' . In whatever proportion the whole refraction wgs is divided, we always can tell the proportion of the dispersions which the two refractions occasion at g and r , and can therefore find the values of s and q . Indeed this solution includes the problem above stated. In it some quantities and ratios are assumed as equal which are not strictly so, in the same manner as in all the elementary optical theorems. The parallelism, however, of $v'v'$ and rr' may be made accurate, by pushing the lens $D\tau$ nearer to Cg , or retiring it from it. We may also, by pushing it still nearer, induce a small divergency of the violet ray, so as to produce accurate vision in the eye, and may thus make the vision through a telescope more perfect than with the naked eye, where dispersion is by no means avoided. It would therefore be an improvement to have the eye-glass in a sliding tube for adjustment. Bring the telescope to distinct vision; and, if any color be visible about the edges of the field, shift the eye-glass till this color is removed. The vision may now become indistinct; but this is corrected by shifting the place of the whole eye-piece. In examining the progress of a red and a violet ray through many eye-pieces of Dollond's and Ramsden's best telescopes, in all of them the colors are united on or very near the field-glass. We meet with many made by other artists, where a considerable degree of color remains, sometimes

in the natural order, and often in the contrary order. This must happen in the hands of mere imitators, ignorant of principle.

Fig. 18 represents the eye-piece of a very fine spy-glass by Mr. Ramsden: the focal length of its object-glass is eight inches and a half, with $\frac{1}{10}$ th of aperture, $2^\circ 05'$ of visible field, and 15.4 magnifying power. The distances and focal lengths are of their proper dimensions, but the apertures are half larger, that the progress of a lateral pencil might be more distinctly drawn. The dimensions are as follow: foc. lengths $Aa = 0.775$ $Bb = 1.025$ $Cc = 1.01$ $Dd = 0.79$ distances. $AB = 1.18$ $BC = 1.83$ $CD = 1.05$. It is perfectly achromatic, and the colors are united, not precisely at the lens Cg , but about one-twentieth of an inch nearer the eye-glass. This combination of glasses may be used as a microscope; for if, instead of the image formed by the object-glass at FG , we substitute a small object, illuminated from behind, as in compound microscopes; and if we draw the eye-piece a very small way from this object, the pencils of parallel rays emergent from the eye-glass D will become convergent to very distant points, and will there form an inverted and enlarged picture of the object, which may be viewed by a Huyghenian eye-piece; and we may thus get high magnifying powers without using very deep glasses. The eye-piece, of which we have given the dimensions, in this way might be made to magnify 180 times with very great distinctness. When used as the magnifier of a solar microscope, it surpasses every thing we have seen. The picture formed by a solar microscope is generally very indistinct; but with this magnifier it seemed perfectly sharp. The only thing which remains to be considered in the theory of refracting telescopes is the forms of the different lenses. Hitherto we have had no occasion to consider any thing but their focal distances; but their aberration depends greatly on the adjustment of their forms to their situations. When the conjugate focuses of a lens are determined by the service which it is to perform, there is a certain form or proportion between the curvatures of their anterior and posterior surfaces, which will make their aberrations the smallest possible. We obtain this formula for a , the radius of curvature for the anterior surface of a lens. $\frac{1}{a} = \frac{2m^2 + m}{2m + 4} + \frac{4m + 4}{2(m)r}$, where m is the ratio of the sine of incidence of the sine of refraction, and r is the distance of the focus of incident rays, positive or negative, according as they converge or diverge, all meeting r' and join v' . By the focal theorem two measured on a scale of which the unit is n , = half of the radius of the equivalent isosceles lens. It will be sufficiently exact for our purpose to suppose $m = \frac{3}{2}$, though it is more nearly $\frac{31}{20}$. In this case $\frac{1}{a} = \frac{b}{7} + \frac{10}{7r} = \frac{42r + 70}{49r}$. Therefore $a = \frac{49r}{4r + 70}$. And $\frac{1}{b} = \frac{1}{a} - 1 = \frac{1 - a}{a}$. For example, let it be required to give the radii of

curvature in inches for the eye-glass b , fig. 12, which we shall suppose of one inch and a half focal distance, and that $e c (= r)$ is $\frac{3}{4}$ inches. The radius of curvature for the equivalent isosceles lens is 1.5, and its half is 0.75. There-

fore $r = \frac{3\frac{1}{2}}{0.75} = 5$, and our formulæ is $a =$

$$\frac{49 \times 5}{42 \times 5 + 70} = \frac{245}{280} = 0.875; \text{ and } \frac{1}{b} =$$

$$\frac{1-a}{a} = \frac{0.125}{0.875}, \text{ and } b = \frac{0.875}{0.125} = 7. \text{ These}$$

values are parts of a scale, of which the unit is 0.75 inches. Therefore

$$a, \text{ in inches,} = 0.875 \times 0.75, = 0.65625$$

$$b, \text{ in inches,} = 7 \times 0.75. = 5.25.$$

And here we must observe that the posterior surface is concave; for b is a positive quantity, because $1 - a$ is a positive quantity as well as a ; therefore the centre of sphericity of both surfaces lies beyond the lens. And this determination is nearly the same with the usual practice, which commonly makes this lens a plane convex with its flat side next the eye; and there will not be much difference in the performance of these two lenses; for in all cases of maxima and minima, even a pretty considerable change of the best dimensions does not make a sensible change in the result. The same consideration leads to a rule which is very simple, and sufficiently exact for ordinary situations. This is to make the curvature such, that the incident and emergent pencils may be nearly equally inclined to the surfaces of the lens. Thus, in the eye-piece with five glasses, A and B should be most convex on their anterior sides; C should be most convex on the posterior side; D should be nearly isosceles; and E nearly plano-convex. But this is not so easy as it appears at first sight. The lenses of an eye-piece have not only to bend the several pencils of light to and from the axis of the telescope; they have also to form images on the axis of these pencils. These offices frequently require opposite forms. Thus the glass A, of fig. 18, should be most convex on the side next the object, that it may produce little distortion of the pencils. But it should be most convex next the eye, that it may produce distinct vision of the image FG, which is very near it. This image should have its concavity turned towards A, whereas it is towards the object-glass. We must therefore endeavour to make the vertical image $f g$ flatter, or even convex. This requires a glass very flat before and convex behind. For similar reasons the object-glass of a microscope and the simple eye-glass of an astronomical telescope should be formed the same way. This is a subject of most difficult discussion, and requires a theory which few of our readers would relish; nor do our limits afford room for it. The artists are obliged to grope their way. The proper method of experiment would be, to make eye-pieces of large dimensions, with extravagant apertures to increase the aberrations, and to provide for each station A, B, C, and D, a number of lenses of the same focal distance, but of different forms; and we would advise making the trial in the way of a solar microscope, and to have two eye-pieces on trial at once. Their

pictures can be formed on the same screen, and accurately compared; whereas it is difficult to keep in remembrance the performance of one eye-piece, and compare it with another. We have now treated the theory of refracting telescopes with considerable minuteness. We cannot add any thing to what Dr. Smith has delivered on the theory of reflecting telescopes. There appears to be the same possibility of correcting the aberration of the great speculum by the contrary aberration of a convex small speculum, that we have practised in the compound object-glass of an achromatic refracting telescope. But this cannot be, unless we make the radius of the convex speculum exceedingly large, which destroys the magnifying power and the brightness. This therefore must be given up. Indeed their performance, when well executed, does already surpass all imagination. Dr. Herschel has found great advantages in what he calls the front view, not using a plane mirror to throw the pencils to one side. But this cannot be practised in any but telescopes so large that the loss of light, occasioned by the interposition of the observer's head, may be disregarded. Nothing remains but to describe the mechanism of some of the best.

We may commence with the reflecting telescope. This was an important improvement on the long and unwieldy refractors, which were in use among astronomers towards the close of the seventeenth century. With a Newtonian reflector, only six feet long, celestial objects may be viewed with as high a magnifying power, and with equal distinctness, as with a common refracting telescope of 120 feet in length. By means of these instruments, the late Dr. Herschel made those brilliant discoveries which have extended our views of the solar system, and of the grandeur of the universe, and which have rendered his name immortal in the annals of astronomy. It was not a little singular, however, that more than half a century elapsed, after the construction of this instrument was suggested by Gregory and Newton, before any reflecting telescope of a size calculated for celestial observation was actually constructed. In the year 1663 Mr. James Gregory of Aberdeen published his account of the construction of that form of the reflecting telescope which bears his name, in a treatise entitled *Optica promota*; and in the year 1672 Sir Isaac Newton constructed two small reflecting telescopes, about six inches in length, of a form somewhat different from that proposed by Gregory, which he presented to the Royal Society: but we hear no more about the construction of reflectors, till the year 1723, when Mr. Hadley published, in No. 376 of the *Philosophical Transactions*, an account of a large Newtonian reflector, which he had just then constructed, and which left no room to fear that this invention would remain any longer in obscurity. The large speculum of this instrument was sixty-two inches and five-eighths focal distance, and five inches and a half diameter, was furnished with magnifying powers of from 190 to 230 times, and equalled in performance the famous aerial telescope of Huyghens of 123 feet in length. Since this period the reflecting telescope has been in

general use among astronomers in most countries of Europe, and has received numerous improvements, under the direction of Short, Mudge, Edwards, and Herschel, the last of whom constructed reflectors of seven, ten, twenty, and even forty feet in focal length, which far surpassed in brightness and magnifying power all the instruments of this description which had previously been attempted.

Plate II. fig. 1 exhibits a general representation of an improved instrument by Mr. Dick. *AB* is the short tube which holds the speculum; *CD* the arm which carries the eye-tubes, which consist of two distinct pieces of mahogany; the part *D* being capable of sliding along the under side of *C*, through the brass sockets *E*, *F*. To the under part of the socket *F* is attached a brass nut, with a female screw, in which the male screw *ab* acts, by applying the hand to the knob *c*, which serves for adjusting the instrument to distinct vision. *G* is the brass tube which receives the eye-pieces. It is supported by a strong brass wire *de*, which passes through a nut connected with another strong wire, which passes through the arm *D*. By means of the nut *f*, this tube may be elevated or depressed, and firmly fixed in its proper position; and, by the nut *g*, it may be brought nearer to, or farther from, the arm *D*. By the same apparatus, it is also rendered capable of being moved either in a vertical or a horizontal direction: but, when it is once adjusted to its proper position, it must be firmly fixed, and requires no farther attention. The eye-piece represented in this figure is the one used for terrestrial objects, which consists of the tubes belonging to a small achromatic telescope. When an astronomical eye-piece is used, the length of the instrument extends only to the point *I*. In looking through this telescope, the right eye is applied at the point *H*, and the observer's head is understood to be uncovered. For those who use only the left eye, the arm would require to be placed on the opposite side of the tube, or the tube along with the arm be made to turn round 180° .

Fig. 2 represents a front or rather an oblique view of the instrument, in which the position of the speculum may be seen. All the specula fitted up by Mr. D. in this form, having been originally intended for Gregorian reflectors, had holes in their centres. The eye-piece was, therefore, directed to a point nearly equidistant from the hole to the exterior edge of the speculum, that is, to the point *a*. In one of these instruments fitted up with a four feet speculum, the line of vision is directed to the point *b*, on the opposite side of the speculum; but, in this case, the eye-tube is removed farther from the arm than in the former case. The hole in the centre of the speculum is obviously a defect in this construction of a reflecting telescope, as it prevents us from obtaining the full advantage of the rays which fall near the centre of the mirror; yet the performance of the instruments, even with this disadvantage, is superior to what we should previously have been led to expect.

The principal nicety, in the construction of this instrument, consists in the adjustment and proper direction of the eye-tube. There is only one po-

sition in which vision will be perfectly distinct. It must neither be too high nor too low,—it must be fixed at a certain distance from the arm, and must be directed to a certain point of the speculum. This position must be ultimately determined by experiment, when viewing terrestrial objects. A person unacquainted with this construction of the telescope, would, perhaps, find it difficult, in the first instance, to make this adjustment; but, were it at any time deranged, through accident or otherwise, the adjustment may be made a-new in the course of five or six minutes.

In pointing this telescope to the object intended to be viewed, the eye is applied at *K* (fig. 1), and looking along the arm, towards the eye-piece, till it nearly coincide with the object, it will, in most cases, be readily found. In this way a person may easily point this instrument to Jupiter or Saturn, or to any of the other planets visible to the naked eye, even when a power of 170 or 180 times is applied. When high magnifying powers, however, are used, it is expedient to fix, on the upper part of the short tube in which the speculum rests, a finder, such as that which is used in Newtonian telescopes. When the moon is the object intended to be viewed, she may be instantly found by moving the instrument till her reflected image be seen from the eye-end of the telescope on the face of the mirror.

Mr. D. has fitted up five or six instruments of the above description, with specula of eight, sixteen, twenty-seven, thirty-five and forty-nine inches focal distance. One of these having a speculum eight inches focus, and two inches diameter, with a terrestrial eye-piece, magnifying about twenty-four times, forms an excellent parlour telescope, for viewing land objects, and exhibits them in a brilliant and novel aspect. When compared with a small Gregorian, of the same size and magnifying power, the quantity of light upon the object appears nearly doubled, and the image is equally distinct. It represents objects in their natural colors, without that dingy and yellowish tinge which appears when looking through a Gregorian. Another of these instruments, having a speculum of 27 inches focal distance, and an astronomical eye-piece, producing a magnifying power of about 100 times, serves as an excellent astronomical telescope. By this instrument the belts and satellites of Jupiter, the ring of Saturn, and the mountains and cavities of the moon, may be contemplated with great ease and distinctness. With a magnifying power of forty times, terrestrial objects appear extremely bright and well defined. Another of these instruments is about four feet long. The speculum which belongs to it is a very old one: when it came into Mr. D's possession it was so completely tarnished as scarcely to reflect a ray of light. After it was cleaned it appeared to be scarcely half-polished, and its surface was variegated with yellowish stains. Were it fitted up upon the Gregorian plan, it would, observes Mr. Dick, be of very little use, unless when a very small magnifying power was applied. Yet, in its present form, it bears with great distinctness a magnifying power of 170 times, and is su-

perior in its performance to a four feet achromatic refractor, with a similar magnifying power. It exhibits very distinct and interesting views of the diversities of shade, and of the mountains, vales, caverns, and other inequalities of the moon's surface. The smallest instrument I have fitted up on this plan is one whose speculum is only five inches and a half focal distance, and one inch and three-quarters in diameter. With a magnifying power of about fifteen times, it shows land objects with great distinctness and brilliancy. But Mr. D. would deem it inexpedient to fit up any instrument of this description with specula of a shorter focal distance than ten or twelve inches.

The following are some of the properties and advantages peculiar to this construction of the reflecting telescope.

1. It is extremely simple, and may be fitted up at a comparatively small expense. Instead of large and expensive brass tubes, such as are used in the Gregorian and Newtonian construction, little more is required than a short mahogany tube, two or three inches long, to serve as a socket for the speculum, with an arm about the focal length of the mirror. The expense of small specula, either plain or concave, is saved, together with the numerous screws, springs, &c., for centring the two specula, and placing the small mirror parallel to the large one. The only adjustment requisite in this construction is that of the eye-tube to the speculum; and, by means of the simple apparatus already described, it can be effected in the course of a few minutes. Almost the whole expense of the instrument consists in the price of the speculum and the eye-pieces. The expense of fitting up the four feet speculum, alluded to above, including mahogany tube and arm, brass sockets, screws, eye-tube, brass joint, and a cast iron stand, painted and varnished, did not amount to £1 7s. A Gregorian of the same size would have required a brass tube at least four feet and a half in length, which would cost four or five guineas, besides the apparatus connected with the small speculum, and the additional expense connected with the fitting up of the joint and stand requisite for supporting and steadying so unwieldy an instrument. While the one instrument would require two persons to carry it from one room to another, and would occupy a considerable portion of an ordinary apartment, the other can be moved, with the utmost ease, to any moderate distance, and the space it occupies is very small.

2. It is more convenient for viewing celestial objects at a high altitude than any other telescope. When we look through a Gregorian reflector, or an achromatic telescope of four or five feet in length, at an object elevated 50° or 60° above the horizon, the body requires to be placed in an uneasy and distorted position, and the eye is somewhat strained, while the observation is continued. But, when observing similar objects by the aerial reflector, we can either stand perfectly erect, or sit on a chair, with the same ease as we sit at a desk when reading a book or writing a letter. In this way, the surface of the moon, or of any of the planets, may be contemplated for an hour or two, without the least weariness or

fatigue. A delineation of the lunar surface may be taken by this instrument, with more ease and accuracy than with any other telescope, as the observer can sketch the outline of the object by one eye, on a tablet placed a little below the eye-piece, while the other eye is looking at the object. For the purpose of accommodating the instrument to a sitting or a standing posture, I caused a small table to be constructed, capable of being elevated or depressed at pleasure, on which the stand of the telescope is placed. When the telescope is four or five feet long, and the object at a very high elevation, the instrument may be placed on the floor of the apartment, and the observer will stand in an erect position.

3. This instrument is considerably shorter than a Gregorian telescope, whose large mirror is of the same focal length. When an astronomical eye-piece is used, the whole length of the instrument is nothing more than the focal length of the speculum. But a Gregorian, whose large speculum is four feet focus, will exceed five feet in length, including the eye-piece.

4. The aerial reflector far excels the Gregorian in brightness. The want of light in Gregorians is owing to the second reflection from the small mirror; for it has been fully proved, by experiment, that, about the one-half of the rays of light which fall upon a reflecting surface is lost by a second reflection. The image of the object may also be presumed to be more correct, as it is not liable to any distortion by being reflected from another speculum.

5. There is less tremor in these telescopes than in Gregorian reflectors. One cause among others of the tremors which affect Gregorians is the formation of a second image at a great distance from the first, besides that which arises from the elastic tremor of the small speculum, when carried by an arm supported only at one end. But as the image formed by the speculum, in the aerial telescope, is viewed directly, without being exposed to any subsequent reflection, it is not so liable to the tremors which are so frequently experienced in other reflecting telescopes. Notwithstanding the length of the arm, of the four feet telescope above-mentioned, a celestial object appears remarkably steady, when passing across the field of view, especially when it is at a moderate degree of altitude; and it is easily kept in the field by a gentle motion applied to the arm of the instrument.

The specula used in the instruments to which we have alluded above, were far from being good, being of a yellowish color, and some of them scarcely half polished. They had likewise large holes in their centre, as they were originally intended for Gregorian telescopes. Were they fitted up in the Gregorian form, they would be of little use, unless with small degrees of magnifying power. Yet, with all these imperfections, they exhibit the object with more brightness and accuracy than the generality of reflectors; and therefore observes Mr. D. have no doubt that, were instruments of this construction fitted up with specula of the best figure and polish, they would equal if not surpass, in brilliancy and distinctness, the general run of achromatic telescopes.

We have now to notice one of the greatest improvements that has been made in the reflecting telescope since the commencement of the present century. It is an instrument constructed by lord Oxmantown, a young nobleman of high mathematical attainments. It may be best described in his own words:—

‘The following considerations,’ observes his lordship, ‘induced me to make the experiments on the specula of reflecting telescopes which I am about to describe. The reflecting telescope would be almost a perfect instrument, could we devise means of freeing it from spherical aberration; it would then retain merely the defects necessarily arising from imperfections in the workmanship, and perhaps some others of a much more trifling nature, such as those derived from the inflection of light. The refractor, however, is not only affected by the spherical aberration in common with the reflector, but also by the different refrangibility of the rays of light. Both of these defects may indeed be in a great degree corrected by giving curves of proper radii to the lenses which compose the object-glass. The spherical aberration may by this be almost entirely obliterated; but a considerable portion of the chromatic aberration still remains, owing to the irrationality of the spectra formed by the different kinds of glass, of which the object-glass is necessarily composed, the different colored rays not being refracted by each in the same proportion. The refractors until lately were limited to a very small scale, owing to the impossibility of procuring suitable glass of large dimensions; and although a new process has lately been discovered on the continent, which has considerably extended the limits of their construction, still I believe that large pieces of glass, of a tolerably homogeneous nature, are procured with great difficulty; and there seems to be but little prospect of our being able, with the present state of our knowledge, to construct efficient refractors, at least with glass lenses of apertures at all approaching the late Sir W. Herschel’s reflectors. I have been thus minute in stating my reasons for making the following experiments, as many practical men whom I have spoken to, seem to think that since Fraunhofer’s discoveries, the refractor has entirely superseded the reflector, and that all attempts to improve the latter instrument are useless.

‘Two modes have been hitherto adopted for diminishing the spherical aberration in reflectors, the one by rubbing down the outer surface of the speculum from the edge to the centre, so as to make its figure approach to that of a paraboloid, the other by increasing the focal length in proportion to the aperture. It is certainly extremely probable that a very skilful workman, who has devoted the greater part of his life to the construction of reflectors, may succeed in some instances, particularly when the instrument is what is technically termed a *dumpy*, in forming a surface approaching to the paraboloid, which will perform better than one which is truly spherical; but when we consider the extreme accuracy necessary, and that a true surface can only be obtained by the process of

polishing, when two motions are combined, the one in some degree at right angles to the other, and that a spherical surface is the only surface which can be formed by these two motions, it will be evident that when we attempt the parabolic form we abandon an essential requisite to the formation of an accurate surface. It is scarcely worth while remarking, that, in every attempt to improve a speculum of an accurate spherical figure, I have invariably rendered it worse; these attempts were not on very dumpy instruments. The other method of diminishing the spherical aberration, by increasing the focal length in proportion to the aperture, is certainly unexceptionable; but it will be immediately evident that it has its limits, and that instruments become unwieldy after they exceed a certain length. I will now immediately proceed to describe one of the instruments I have constructed, with a view of diminishing the spherical aberration without introducing either of these defects:—

‘In fig. 3, plate II., AB is a brass plate turned true on both sides by means of a slide apparatus, which at the same time renders its sides parallel. The dimensions are seven inches by five-eighths thick. CD is another brass plate, made true by the same means, half an inch thick. The two plates were then screwed together in a temporary manner, their centres coinciding; three holes were then bored through them one-fourth of an inch in diameter, accurately perpendicular to their surfaces. The two plates were then unscrewed, and the holes in the plate CD were carefully tapped with a tap, having one-sixtieth of an inch interval between its threads. Three cast steel spindles were then accurately turned, the shank EF being made to fit the holes of the plate AB, and the screw GH nicely to fit the holes in the plate CD. It is almost needless to observe that the flanches, and indeed every part of the spindles, must be very carefully turned. The three cast steel spindles were then put through the holes in the plate AB, till their flanches rested on it. They were secured there by washers I, K, put on the shanks of the spindles at the back of the plate, and the washers were retained in their places by milled nuts L, M. To prevent the washers from shaking as the steel spindles were turned backwards and forwards, which would loosen the milled nuts, each washer was provided with a screw on its side O, which enters the groove P in the shank, and keeps it steady. The plate CD was then laid upon the three screws GH of the spindles, which were then gradually turned round in succession by a key fitting their other ends till the plate CD reached within about one-eighth of an inch of their flanches. To prevent the spindles from shaking either in the plate AB, or CD, F lateral holes were drilled reaching the principal holes *o, o, o, v, v, v*. These were stuffed with small bits of leather, which were kept constantly pressed against the spindles by small screws. This precaution is essential. Besides, screws were inserted at the back of the plate through the holes marked *i, i, i*, which were screwed against the plate CD, to prevent the possibility

of its shaking in the slightest degree during the operation of grinding and polishing the speculum.

'The mechanism being now complete, a speculum was cast one inch thick. This was secured to the plate CD by three small screwed wires cast into it, by a groove in the plate CD, and by a cement composed of resin, wax, and sulphate of lime. A ring of speculum metal was also cast one inch and a half thick, which was secured to the plate AB in a similar manner, leaving a very minute interval between it and the piece of speculum metal it surrounded. The whole together formed a speculum of six inches aperture, and two feet focal length, which was ground and polished in the common way, till by repeated trials it was found to be of a good spherical figure. The small screws *i, i, i*, were then drawn back, the speculum placed in the tube, and the spindles turned round a certain number of times, by which the centre part of the speculum was made to approach nearer the plate AB, by a quantity ascertained in a manner I shall presently point out. The two images were then made to coincide, and the image was then found to be apparently as distinct as either image had been when separate. It is necessary to observe that, in order to effect the adjustment properly, each image must be brought to the same degree of brightness, which can be accomplished by shades on the mouth of the telescope, and that no higher power should be used than each metal, when separately employed, can bear with distinctness.

'I rather think that instruments of this construction will pretty frequently require adjustment; however, this is easily effected in the space of two or three minutes. The first I attempted consisted of a solid metal surrounded by two rings. Owing to a defect in the mechanism it required very frequent adjustments, the smallest shock displacing the images. The one I have described is almost entirely free from this defect, remaining in perfect adjustment even after very violent shocks. I have a speculum like the first I made, consisting of three parts, which is almost ready for grinding; and I expect it will turn out well. I have not yet perceived any ill effects from expansion and contraction, which was the difficulty I most apprehended. Whether they will become perceptible in instruments of higher powers, or whether, if perceived, means may or may not be devised of obviating them, can only be ascertained by future trials. On my return from parliament, if other avocations do not interfere, I propose to construct a speculum in three parts of eighteen inches aperture and twelve feet focal length;—this will be giving the experiment a fair trial on a large scale. It may perhaps be as well to observe that I do not think the principle of subdividing the aberration can be applied with advantage to small instruments. The object to be gained by it is a diminution of the focal length with a given aperture and power, and this is by no means desirable in small instruments, as it forces us to make use of deep eye-glasses, which are on many accounts objectionable.

'To compute the respective lengths of the

curves composing a compound speculum, such as has been described, so that the aberration of the whole speculum may be equally divided between them.

'Let E, fig. 3, be the centre of the surface. Let a ray proceed from Q and intersect the axis in V. Let *q* be the geometrical focus of rays proceeding from the point Q.

Let *q* represent E Q, Let *q'* represent E v

$$\frac{q'}{f} \quad \frac{E q, \theta}{E F, v} \quad \frac{R E A}{v \sin \theta}$$

Then considering *q'* a function of $\text{ver. sin } \theta$, *v* being of course = 0 in each coefficient, we have

$$q' = q' + \left(\frac{d q'}{d v}\right) v + \frac{1}{1 \cdot 2} \left(\frac{d^2 q'}{d v^2}\right) v^2 + \&c.$$

which by proper substitutions becomes

$$q' = \frac{q \cdot f}{q + f} + \frac{q^2 f v}{(q + f)^2} + \frac{q^3 f^2 v^2}{(q + f)^3} + \&c.$$

The aberration being *q' - q* is evidently represented by this series without its first term, which, expressed geometrically, amounts to

$$\frac{Q E^2}{Q F^2} \cdot \frac{A N}{2} + \frac{Q E^3}{Q F^3} \cdot \frac{A N^2}{4 E F} + \&c.$$

which, when the rays are parallel, becomes

$$\frac{A N}{2} + \frac{A N^2}{4 E F} \&c.$$

'It is evident that the first term of this series will afford a sufficiently near approximation for compound specula; if we therefore represent the *ver. sines* of the arcs DO, DP, DQ, fig. 3, by AN, AN', AN'', the problem becomes, Given AN = AN' - AN = AN'' - AN', the length of the arc DQ and its radius, to find the lengths of the arcs DO and DP.

'Example.—Let *a* be the arc DQ = 3 inches, *r* its radius = 48 inches, *x* the seconds in *a*, then $x = 206265 \frac{a}{r} = 206265 \frac{1}{16} = 12891''$, which in degrees amounts to 3° 35' whose *v. s.* = .0019550.

$\frac{1}{2}$ of which = .0006516, corresponding to arc, 2° 4' = 7440" = 1.77 inches.

$\frac{1}{3}$ of which = .0013034' corresponding to arc 2° 54' 30" = 10470 = 2.44 inches.

arc DO = 1.77 inches, and DP = 2.44 inches.

'It is evident that the arc PO must be drawn back, a quantity equal to D'C' = $\frac{1}{2}$ DC, and DO must be drawn back 2 D'C' = DC.'

We have in the article OPTICS fully explained the principle of a reflecting specula mirror for telescopes, and it may now be advisable to furnish our readers with some important particulars in the art of annealing this part of the instrument. It is from the pen of Dr. McCulloch, and was published in the Journal of Science for June, 1828. Dr. McCulloch commences his paper by the following observations:—

'It is much more than twenty years since I spent some time in constructing specula for reflecting telescopes; nor, till very recently, had I any reason to conjecture that in any part of the process, which it was my lot, like that of others, to labor through for myself, I was possessed of

knowledge which was not equally known to every one who had attended to this subject, much more to the makers of such telescopes. Having lately, however, had an opportunity of conversing with Mr. Ramage about his processes, I believe that there is one point at least which has been misunderstood, and, consequently, often mismanaged; the result being the production, by accident, of good metals, perhaps one good metal only, among many failures, when, if I am right, those may be produced with comparative certainty, and possibly in such hands as those of Mr. Ramage himself with absolute precision. It may perhaps, indeed, be considered that it is wrong here to suppose that because this excellent constructor has overlooked a necessary portion of his process, others should be supposed to have done the same; but, as I have no means of ascertaining what are the knowledge and practice of the different makers, I must even hazard the chance of here attempting to teach any one what he knew before; while I must still trust that some may hereafter derive, from my experience, precautions by which they will be saved considerable disappointment and some expense. Such is the apology for this paper, should it prove superfluous to any one; while I cannot help considering the subject as of some importance, as, not merely the color of the metal, but, as I think, its durability, and its power of giving a clear image, depend much on the nature of the management in that part of the process to which I allude.

I am not aware that it is necessary to say any thing respecting the proportions of the two metals in the alloy; though I would caution makers of specula respecting the purity of the tin and copper, being convinced by some trials that the presence of arsenic is apt to lead, in time, to the tarnishing of the surface. I must equally presume that every one is acquainted with the temperature required for the separate metals before mixing, with the necessary flux, the method of pouring in the alloy, the position of the mould, and so forth; though with respect to the best form of the metal itself, that is as to relative thickness in its several parts, I must confess that I have never yet been able to satisfy myself: such are the complicated difficulties, entangled between the cooling and annealing first, and the optical consequences afterwards depending on changes of temperature, and on weight or flexure, that beset any calculations on this subject; while it is probable that they are really irreconcilable, or that there is no one form which will be the best, as concerns the original nature of the metal and its action when completed.

To pass from these points, therefore, the object to which I am desirous of especially calling the attention of those who may be interested in this question, is the process of annealing the metal after casting, since it is in this, as far as I have found, that the chief disappointments take place; and in consequence of a species of mismanagement which attention will be able to prevent when once the principle has been explained. Here it is at least that I did fail myself, until I contrived to examine and discover the cause; and here it is that Mr. Ramage has found the same difficulties, and made the same failures—

not likely, I trust, to happen often again, though, in a process so delicate, certainty must not always be expected.

I need scarcely say that if this alloy were suffered to cool rapidly it would break, or might break, and that it requires to be cooled slowly in the mould, or annealed; this being true, particularly of the larger metals, as there is not so much hazard with respect to small ones. The process itself is simple and easy: it would scarcely, indeed, be necessary to describe it were it not for its frequently injurious consequences; and it consists commonly in covering the metal in the mould with hot ashes or cinders, and thus retaining it, often for a considerable time and at a high temperature.

To state now what those failures are, before enquiring into the cause,—I must first remark, that the fracture of speculum metal ought to be that which mineralogists term flat conchoidal, or resembling that of gun-flint; and the surface of the fracture ought to be lucid and smooth, or like that of glass, utterly free of granulation or roughness of any kind, and as polished in reality as it can afterwards be rendered on the tool. Without this, it is in vain to expect the greatest light which a speculum is capable of giving, nor the purest color; and without this, also, it will be found that the surface will be apt to fail after long use, or in consequence of frequent exposure to the atmosphere and vacillations of temperature. A speculum metal, therefore, which does not thus come out at the annealing, ought to be rejected; it is not worth the subsequent labor.

It is true, that, as far as four inches diameter, a very moderate degree of care will generally insure success; the difficulty occurs in the larger ones, and increases rapidly with their increase of size. And the failure consists in the reverse of what I have just stated. The fracture becomes granular or rough, and is at the same time dull as might be anticipated; while the degree of this fault varies with the extent of the mismanagement; which is a mismanagement in the annealing alone, as I shall presently show, while the nature of the metals used, or something in the flux, or in the casting, is often accused for faults depending on a much simpler cause.

Nor is it only that the metal is dull from the nature of the fractured surface, or that this is a mere deception which the polishing will remove. So far from that, the absolute color of the alloy itself is imperfect or bad; it has no longer that clear silver whiteness which will take what is technically called a black polish, but is gray and sometimes of different tones, often so gray and so dark as to be palpably unfit for its purpose, though often, in the least imperfect instances, retained and finished for use, with the production assuredly of some disappointment even at first, and of somewhat more, I have fully ascertained, after long use, as I shall presently explain.

In such cases of extreme failure, as the blame is generally laid on the metals of the alloy, the fault remains uncorrected; and if others have found the same difficulties as I at first encountered myself, and as Mr. Ramage had always

done when I inspected his processes, they will be well pleased to know where the error lies; though it must still depend on a nicety of attention which it is impossible to describe to find the remedy.

‘Could the speculum be suddenly or quickly cooled after casting, it would be always perfect; the evil is the result of slow cooling—of that very process which is necessary, or thought necessary, to secure its integrity; and the slower the cooling the greater the evil or the failure. Or, by rapid cooling, the texture and the color are the most perfect which can be obtained from this alloy; while it is possible, by a proceeding as highly reverse as possible, to render it absolutely useless, and utterly unlike to what is desired; and even while the most rigid analysis shows that the bad metal and the good are precisely the same after having been cast, if we should not be satisfied as to this, from having produced by those different treatments a perfectly good and an extremely bad metal out of the same pots at the same time.

‘There ought now to be no difficulty in seeing what the efficient cause of this evil is. It is the crystallisation of the alloy, permitted or encouraged by the application of too high a heat in the annealing, and by continuing that heat too long. Nor is fluidity necessary to this process; it occurs after the metal is consolidated, as I have amply proved; since it is even easy to bring a metal to this state by annealing, after having been thoroughly well cast and annealed, and after having been tried by fracture. Nor is it a fact to excite any surprise, since it belongs to a wide train of analogies on which my experiments, long since ready to be made public, amount perhaps to thousands.

‘We can now, therefore, trace the cause of all those variations of defect, which occur in this case, between the best and the worst specimens; as it will be found that the degree of crystallisation on which depend the faults, is always proportioned to the extent to which the annealing process has been carried; or on the duration and the intensity of the heat applied to the metal after consolidation. The reason of this, also, is apparent; but I need not, in this merely practical notice, enter into a subject which I have treated fully in a paper of another nature.

‘But, to convince observers that this is the real cause of the defect of such metals, it is always easy to dissect the crystallisation, if I may use such a term, by means of an acid, and thus to see how the defect goes hand in hand with the crystallisation, while the variety of texture in speculum metals thus discovered will also be found very considerable, and often, I may add, very unexpected; since, among other singular varieties not easily described, I have found even examples of what mineralogists call the spheroidal concretionary structure.

‘But, if I dare not here dwell on the properly theoretical part of this subject, I must suggest one circumstance or change, which, under high or extreme degrees of annealing, seems to occur, and which is probably the real cause of the defect as to color, since it is not so easy to suppose that mere texture could produce a gray

tint, such as is often found in these defective metals. I call it a suggestion, because, while engaged in these investigations, I was never able to discover any method of analysis by which the fact, if it be one, could be ascertained.

‘The suggestion is simply this,—that under the complete liberty of crystallisation permitted by high and long-continued heat, an alloy is formed different from that which was intended; or that a certain definite combination takes place between the tin and copper, so as to produce a mixture which is possibly that of two alloys, or else is such as to set a portion of one or other of the metals free, though of course under a state of mixture which is unassignably minute. It is plain that this is at best a probable state of things, while I need not say how difficult the proof must be at present. It is probable, for this reason: there is a crystallised metal or alloy, crystallisation takes place only in simple bodies or definite compounds, and it would be very singular if the proportion of twenty-five copper and twelve tin, which was my compound, should be that definite compound, while as other proportions are used by Mr. Ramage, such an occurrence cannot, plainly, happen in both cases. And, in defect of analysis, it has often seemed to me, on the trial by acids, that there was more than one substance in the defective and crystallised speculum, distinguishable by the manner in which the acid acted on the surface. It might not be very difficult to approximate to this point to a greater nicety by the application of different acids, and by a subsequent examination of the proportions of tin and copper dissolved; but what I neglected to do, when I had the power, my state of health has long prevented me from following up.

‘It seems unnecessary to add more on this part of the subject in a paper so merely practical; and if I ought now to show how the annealing ought to be carried on, so as to avoid the evil in question, I find it very difficult to give such directions as will enable any one to do as I have done in these cases with success. And, indeed, it can scarcely be necessary; since the general principle, and the cause of the evil having been once explained, it will be easy for the speculum-maker to apply what, after all, must be a matter of trial, and which must also vary with each magnitude of speculum. I could not describe a temperature for which there is no measure, nor lay down a period of time which must depend partly on that temperature, and partly on the size of the metal, and partly also, I may add, on its form and thickness, and even on the temperature of the atmosphere. But if each maker must feel his way for himself, and for each size that he may cast, let him always remember that the speculum metal is rather a mixture than a true alloy, and that it has a tendency to separate as to crystallise, when under liberty, by heat; that the best and most brilliant metal is that which cools most suddenly, or which is soonest deprived of the power of crystallising, and therefore that his object must be to cool his speculum as rapidly as it can possibly be cooled without breaking. And, as to the practical method of annealing, I may add that I think the ordinary

mode bad, inasmuch as it is difficult to regulate. Whether my own method may prove better in other hands or not it is not for me to pronounce, but it was to use sand for that purpose. In this case the mass of sand was placed over a horizontal iron-plate flue, so as to be at a high red-heat in one place and to cool gradually at another; and while the speculum was placed in the hottest part after casting, it was slowly moved to the cooler parts till the desired end was obtained.

'I have but one other suggestion to offer as to the effects which have seemed to me to follow from polishing for use, specula, of which the texture had been thus crystallised. Whether there should be two alloys, or an alloy and a metal, or not, or whether the whole result is mechanical, depending on the intersected surface of this confused crystallisation, it is certain that a polished surface of this nature is irregular in its action on light, and that good images are scarcely attainable, from optical causes that will be sufficiently obvious, to say nothing of an absolute loss of light produced by this cause. And I have further reason to believe from numerous experiments, which it would be impossible as improper to detail here, that such crystallised specula undergo further changes of their crystalline texture from the ordinary vacillations of temperature to which the uncrystallised ones are either less subject, or from which they are exempt; the consequence being a slow deterioration, as may easily be imagined without further explanation. To this cause, indeed, we must, I believe, trace some of the deteriorations of specula which do not depend on tarnish or corrosion, though I must also add, in concluding, that the crystallised specula are more easily tarnished than others, probably from the irregular action of moisture on them, or, possibly, because the definite compound and its associate thus intermixed, one or other, or both, offer less resistance to the air than that mixture of tin and copper which constitutes a good speculum.'

We may now furnish our readers with some particulars of the powerful achromatic telescope, constructed by M. Lerebours. On this subject we may best quote the opinions of Messrs. Herschel, South, and Amici.

'The diameter,' says Mr. South, 'of the object-glass of the achromatic telescope, constructed by M. Lerebours, now in the Royal Observatory of Paris, is rather better than 9.2 inches English, uncovered by the cell, but of which 8.4 inches only are in actual use. Its focal length is eleven feet.

'The magnifying powers with which I used it, on the night of the 15th of March last, are 136, 153, 224, 240, 420, and 560. With all, except 560 (which, by some forgetfulness, was not applied), Venus was extremely well defined during a dark night; of course, Jupiter and Saturn were well shown. The two stars of Castor, of γ Leonis, of ζ Orionis, were exhibited with 240, 420, and 560, as round as possible, ω Leonis presented by its side a light blue star with 420, which could not be overlooked by the most careless observer, and with 560 both stars were admirably defined.

'I need not inform you that a telescope, having an object-glass of the diameter above-mentioned, which, with these powers, will neatly define the limb of the planet Venus, and will give to the discs of the double stars here named images absolutely round, deserves to be well spoken of. Indeed, I have no hesitation in saying that this telescope is the best achromatic I ever pointed to the heavens; nor will I withhold my regret, or even the mortification I feel in asserting, that England, when I visited it in May last, could not produce an achromatic anything like it. The stand upon which it is mounted is not provided with any means of giving to the telescope equatorial motion.

'Whilst, however, I say thus much, I am far from entertaining the sentiments of Mr. Fraunhofer, as to the decided superiority of refractors over reflectors, nor can I accompany Mr. Struve in his idea, that the Dorpat telescope 'may perhaps rank with the most celebrated of all reflecting telescopes, namely, Herschel's.' It is true, I have not had the enviable qualification of having seen the former; still I think the Paris telescope furnishes me with data upon which to form something like a rational conjecture.

'Its object-glass actually in use is in proportion to Mr. Struve's (if all of it be effective), as seventy to ninety-two nearly, a difference not very hard to be allowed for.

'I have seen the nebula in Orion; the planets Jupiter and Saturn, with the Paris telescope; and with their appearances in Mr. Herschel's twenty feet reflector, I am perfectly familiar, and the comparison is many times in favor of the latter.

'The power of the twenty feet reflector at Slough is well authenticated; and if the indefatigable astronomer of Dorpat will turn his probably matchless achromatic upon some of the faint nebulae in the constellation Virgo, or upon some others, not easily resolvable into stars, he will soon satisfy himself, that his ideas of its space penetrating power are much overrated.

'The star ζ Bootis was seen 'close double' by Mr. Pond at Lisbon, perhaps twenty years ago, and, as I believe, with a Newtonian reflector of six inches aperture, and the circumstances mentioned in a letter written by him to Dr. Wollaston. The instrument with which I first observed it, in 1810, 'close double,' was a reflector of the worst possible construction, viz. a Gregorian reflector of six inches aperture, and thirty inches focal length, but a very perfect instrument, made for me by Mr. Watson in the year 1809, and which is now in the possession of my friend Mr. Perkins.'

After speaking of the merits of the telescope of M. Lerebours, Mr. Herschel proceeds as follows:—

'My object, in writing this, is to obviate an erroneous impression that may arise in the minds of those who read Mr. Fraunhofer's Memoir, as to the great inferiority of reflecting telescopes in point of optical power to achromatics in general, and more especially to those constructed with such delicacy as his own doubtless are. Those who have witnessed the performance of M. Amici's beautiful Newtonian reflector will not

readily admit this inferiority, but will feel disposed to wish that some attempt might be made to accommodate such admirable instruments to the more exact purposes of astronomy, an object which appears to have been too easily lost sight of.

Mr. Fraunhofer's expressions, when speaking of the loss of light by metallic reflection, are, I think, too strong. He observes that 'the most perfect metallic mirror reflects only a small part of the incident light, and that the greater part is absorbed;' and that, in consequence, the intensity of the light entering the eye of the observer is always very small.' A metallic mirror, however, reflects 0.673 of the incident light, or more than two-thirds, and absorbs less than one-third of the whole. M. Fraunhofer appears rather to have in view the Newtonian construction, where two metallic mirrors are used, and where the whole effective quantity of light is only 0.452 of the incident rays. No one who has been half blinded by the entrance of Sirius, or of α Lyrae, into one of my father's twenty feet reflectors, will say that the intensity of its light is small, nor, to take a less extreme case, will any one who uses one of M. Amici's Newtonian reflectors of twelve inches aperture (a perfectly convenient and manageable size, and of which he has constructed several), be disposed to complain of its want of light. The ordinary reflector used by my father, in his reviews of the heavens, was a Newtonian, seven feet focus, and barely six inches in aperture; and consequently equal, *ceteris paribus*, to an achromatic of $4\frac{1}{4}$ (4.254) English, or 3.999 Paris inches, and therefore by no means proper to be put in competition with M. Fraunhofer's chef d'œuvres of seven and nine inches; yet it will be recollected that with this telescope, and with a magnifying power of 460, ω Leonis was discovered to be double, and distinctly separated, and its angle of position measured.

In order to demonstrate the superiority of reflecting over reflecting telescopes, M. Fraunhofer has selected the star ζ Bootis, which my father has described as a double star of the sixth class (No 104), in his second catalogue of double stars, but without mentioning the division of the large star into two, as a double star of the first class. It might, however, be very easily overlooked in a review in indifferent weather. It is, at least, as difficult to resolve as η Corone, more so than σ , either of which, with any telescope, be its goodness what it may, requires a favorable atmosphere for its separation. From this omission, however, Mr. Fraunhofer concludes that the power of the telescope was insufficient to resolve it, and must, therefore, have been inferior to that of an achromatic in the hands of Mr. Bessel, with which it was recognised by that eminent astronomer as double. It will be seen, in reference to the memoir on Double Stars by Mr. South and myself, that this star had been long since ascertained to be double, not only by Mr. Bessel, but by Messrs. Struve, Pond, and South, and, what is more to the present purpose, by Sir W. Herschel himself. It was only by oversight that we omitted to refer, in that work, to his account of it, which is published in his paper On the Places of 145 new Double Stars,

in the first volume of the Transactions of the Astronomical Society, p. 178, and read in June 1821.

In large reflectors, in which only one metallic mirror is used, the disadvantage, in point of light, under which they labor, in comparison with refractors, is, however, much less formidable. A reflector of eighteen inches aperture would be equivalent to an achromatic of fifteen and a half, and one of forty-eight inches to an achromatic of forty-one and a half in aperture: a size we cannot suppose (from any thing we have yet seen) that it is possible the latter should ever attain. Reflectors of eighteen or twenty inches are perfectly manageable, and, I apprehend, quite within the power of any good artist to execute, and (if intended only for use, and not at all for show) at no very ruinous expense. That which I habitually use, of the former dimension, is my own workmanship; and, though inferior in distinctness to the exquisite one used by my father in his sweeps, is by no means an instrument to be despised. Indeed, from the experience I have had of these telescopes, I am satisfied of their applicability, even to the more exact purposes of astronomy, and that great improvements in their construction and mechanism remain to be made.

Having succeeded in observing the eclipses of Jupiter's satellites in the day time, and in measuring the diameters with one of his Newtonian reflectors, professor Amici was desirous of ascertaining the dimensions of an achromatic telescope, capable of showing these phenomena with the same distinctness.

'With this view,' says he, 'I took a Newtonian telescope of my own making, having a focal distance of thirty inches, and an aperture of thirty-six lines, and I compared with it an achromatic telescope of the same length, having an English object-glass of two lenses, two inches and a half diameter. In applying to these instruments two equal eye-glasses, and directing them to the same object, I saw this object with most brightness through the achromatic telescope. In order to be certain of this fact, I constructed a paralleloiped, three inches long, by placing, in opposite directions, two prisms, one of colorless, and the other of obscure glass, such as those which are employed for observing the sun. This apparatus furnished a regular gradation of transparency; by placing it between the eye of the eye-glass, I could easily find the opacity necessary for intercepting entirely the light of the object which I looked at alternately with each instrument. In order to avoid all calculation, I diminished by diaphragms the aperture of the brightest telescope, till the light of the object was extinguished in the two apparatuses at the same division of the paralleloiped. After several trials I found that, in order that the refractor and the reflector should have the same brightness, the first must have an aperture of twenty-seven lines, and the second of thirty-six. I am of opinion, indeed, that this ratio of 3 to 4 ought to be the same for telescopes of all dimensions, as we cannot take into account the slight loss of light arising from the great thickness of the two glasses in these telescopes.

In order, then, to see the satellites as bright as I have seen them, we require an achromatic

telescope of eight inches and a half in diameter, and having a focal distance such that the instrument may magnify 400 times. The great object-glass, therefore, of seven inches and a half aperture at Naples, will show the satellites less distinctly than mine, while the nine inch object-glass at Dorpat will show them more distinctly.

‘The result obtained by Sir W. Herschel does not differ from the above. By the method of Bouguer he found that the diameters of a double achromatic, and of a Newtonian reflector, must be as 7 to 10, in order to produce the same brightness with the same magnifying power, or as 5 to 6, if the small Newtonian mirror is not used. Hence, in order that an achromatic telescope may equal his forty feet reflector, its object-glass must be forty English inches in diameter.

‘If reflecting telescopes, for which I have a partiality, have, in general, the advantage over

refractors, with respect to the distinctness of the images, magnifying power, and smaller focal distance, they must always yield to the latter on account of the smaller apertures which these require, the facility with which they may be applied to different instruments, and the immutability of the substance of their lenses, which render comparable observations made at distant epochs, and partly from the convenience of using them, arising from this, that the object-glass preserves always the well centered position which the artist has given it. This last quality is so much valued, by some observers, that they do not hesitate to prefer a moderate achromatic telescope to a good Newtonian one.’

We shall now present, in a small table, the relative performances of achromatic telescopes, with double object-glasses, and Newtonian reflectors, according to Sir. W. Herschel, Mr. Herschel, and Professor Amici.

Ratio of diameters when the performance is equal.

	Achromatic.	Reflector.	
1. When the reflectors have a small mirror	7.	to 10	} Sir W. Herschel.
2. When the small mirror is not used	8 $\frac{1}{4}$	to 10	
3. When the reflectors have a small mirror	7 $\frac{1}{10}$	to 10	} Mr. Herschel.
4. When the reflector has a small mirror	7 $\frac{1}{2}$	to 10	

Professor Barlow has suggested a new fluid telescope which is deserving of attention. He employs sulphuret of carbon for a correcting medium as a substitute for flint glass in the achromatic instrument. This is enclosed between two plate glasses, ground and polished to the proper curves, and placed at any distance behind the plate front lens, from actual contact to two-thirds of the focal length of the plate. This being premised, it may be observed that, in the usual construction of achromatic telescopes, the two or three lenses composing the object-glass are brought into immediate contact, and in the fluid telescope proposed by Dr. Blair the construction is the same, the fluid having been enclosed in the object-glass itself. Nor could any change in this arrangement in either case be introduced with advantage; because the dispersive ratio between the glasses in the former instance, and between the glass and fluid in the latter, is too close to admit of bringing the concave correcting medium far enough back to be of any sensible advantage. The case, however, is very different with the sulphuret of carbon. The dispersive ratio here varies (according to the glass employed) between the limits .298 and .334; which circumstance has enabled me to place the fluid correcting lens at a distance from the plate lens equal to half its focal length; and I might carry it still farther back, and yet possess sufficient dispersive power to render the object-glass achromatic. Moreover by this means the fluid lens, which is the most difficult part of the construction, is reduced to one-half, or to less than one-half of the size of the plate lens; consequently to construct a telescope of ten or twelve inches aperture involves no greater difficulty in the manipulation than in making a telescope of the usual description of five or six inches aperture, except in the simple plate lens itself: and, what will be thought perhaps of greater importance, a telescope of this kind of ten or twelve feet length

will be equivalent in its focal power to one of sixteen or twenty feet. We may therefore by this means shorten the tube several feet, and yet possess a focal power more considerable than could be conveniently given to it on the usual principle of construction. This will be better understood from fig. 4, plate II.

In this figure A B C D represent the tube of the six inch telescope, C D the plate object-glass, F the first focus of rays, *de* the fluid concave lens, distant from the former twenty-four inches. The focal length M F being forty-eight inches, and, consequently, as 48 : 6 :: 24 : 3 inches, the diameter of the fluid lens. The resulting compound focus is 62.5 inches; it is obvious, therefore, that the rays *df*, *cf*, arrive at the focus under the same convergency, and with the same light, as if they proceeded from a lens of six inches diameter, placed at a distance beyond the object-glass C D (as C' D'), determined by producing these rays till they meet the sides of the tube produced in C' D', viz. at 62.5 inches beyond the fluid lens. Hence it is obvious the rays will converge as they would do from an object-glass, C' D', of the usual kind, with a focus of ten feet five inches. We have thus, therefore, shortened the tube 38.5 inches, or have at least the advantage of a focus 38.5 inches longer than our tube; and the same principle may be carried much farther, so as to reduce the usual length of refracting telescopes nearly one-half, without increasing the aberration in the first glass beyond the least that can possibly belong to a telescope of the usual kind of the whole length. It should, moreover, be observed that the adjustment for focus may be made either in the usual way or by a slight movement of the fluid lens, as in the Gregorian reflectors by means of the small speculum. In the latter case the eye-piece is fixed, which may probably be convenient for astronomical purposes, in consequence of the great delicacy of the adjustment.

TELESIA, in ancient geography, a town of Italy in Campania. It was taken by Hannibal Liv. 21. c. 13, &c. It is now called Telese.

TELESILLA, a lyric poetess of Argos, who bravely defended her country against the Spartans.—Paus. ii. c. 20.

TELESINUS, a general of the Samnites, who joined the party of Marius, and fought against the generals of Sylla. He marched towards Rome, and defeated Sylla himself with great loss. But at last he was defeated and killed in a bloody battle, after displaying the utmost bravery.—Plut.

TELFORD (Thomas), civil engineer, was born at Langholm in Dumfriesshire, Scotland, in the year 1755, which he quitted at an early age, and, acquiring a knowledge of the bricklayer's and stonemason's trades, rose gradually from such an humble position, to the undisputed head of the profession of civil engineers. While Telford was employed in building with his own hands the round of the village school at Inverness, Alexander Nimmo, who subsequently rose to the head of the profession of civil engineers in Ireland, was instructor of the children; and these two distinguished men preserved the closest intimacy to their latest moments. In industry, integrity, and professional ability, Telford has not been exceeded. His works are so numerous, as to render individual or separate description inconvenient here. It must suffice to mention the most public and valuable; they are the Menai and Conway Bridges—Caledonian Canal—Aqueducts at Pont-y-Sysyllte and Chirk (N. Wales)—Holyhead road through the North Wales mountains—St. Katherine's Dock, London—Highland roads, and Salopian canals. He may be said to have been the founder of the Society of Civil Engineers, an Institution over which he presided until within a few weeks of his decease in 1834, and to which he bequeathed £2000, together with library, maps, and instruments. In early life Telford exhibited a taste for poetry, and was author of several small pieces, that do not by any means lessen the estimate formed of his genius. His remains were deposited in Westminster Abbey, whither they were followed by many of the members of the Institution of Civil Engineers.

TELINGANA, an ancient kingdom of Hindostan, now divided between the British and the Nizam. It was intersected by the river Godavery. The districts lying to the north of that river were called Andhra; those situated on the south of it, Kalinga. The Telinga language is still spoken by the Hindoos. Between Ganjam and Pulicat, it contains a number of Sanscrit words, and has some affinity to the Bengaly.

TELL, *v. a. & v. n.* } *Pret. and part. pass.*

TELLTALE, *n. s.* } told; Sax. *tellan*; Belg. *taellan*, *tellen*. To utter; express; speak; relate; teach; discover; number; give an account: a telltale is one who gives petty or malicious information.

You speak to Casca, and to such a man

That is no bearing telltale. *Shakespeare, Julius Cæsar.*

'Tis done: report displays her telltale wings,

And to each ear the news and tidings brings.

Fairfax.

Numerous sails the fearful only tell;
Courage from hearts, and not from numbers, grows.

Id.

Eurydice and he are prisoners here,
But will not long be so: this telltale ghost
Perhaps will clear them both.

Id. and Lee.

A child can tell twenty before he has any idea of infinite.

Locke.

She doubts if two and two make four,
Though she has told them ten times o'er.

Prior.

The rest are vanished, none repassed the gate,
And not a man appears to tell their fate.

Pope's Odyssey.

TELL (William), an illustrious Swiss patriot, the chief instrument of the revolution which delivered the Swiss cantons from the German yoke in 1307. See SWITZERLAND. Animated by William Tell's courage and patriotism the Swiss flew to arms; attacked and vanquished Griser, who was shot to death by Tell; and the association for the independency was immediately formed. Tell was offered the government, but he refused it. While endeavouring to alter the course of a torrent, and prevent its farther desolations, he was carried off by the impetuous stream in 1354.

TELLIAS, or TELLIS, a famous astronomer and soothsayer, of Elis, who flourished in the age of Xerxes.—Paus. x. 1.

TELLICHERY, a sea-port town of the south of India, province of Malabar. It is a place of considerable consequence, and ships of great burden may safely anchor opposite it, at two miles distance, in six fathoms water. The East India Company established a factory here, for the purchase of pepper, &c., so early as the year 1683, and in 1708 purchased the fort from the Colastry, or Cheralah rajah.

TELLINA, in zoology, a genus of anima belonging to the class of vermes, and order of testacea. The animal is a tethys; the shell is bivalve, generally sloping to one side, with three teeth at the hinge. Gmelin reckons about ninety species. The tellina bury themselves in the mud or sand at the bottom of the sea, keeping a communication with the water above by means of short tubes or pipes.

TELLURIUM, in mineralogy, a new metal which Mueller first suspected to exist in the aurum paradoxicum or problematicum, which has the appearance of an ore of gold, though very little can be extracted from it. Klaproth afterwards established its existence, not only in this but in some other Transylvanian ores, and named it tellurium. Pure tellurium is of a tin white color, verging to lead-gray, with a high metallic lustre; of a foliated fracture; and very brittle, so as to be easily pulverised. Its specific gravity is 6.115. It melts before ignition, requiring a little higher heat than lead, and less than antimony; and, according to Gmelin, is as volatile as arsenic. When cooled without agitation, its surface has a crystallised appearance. Before the blowpipe on charcoal it burns with a vivid blue light, greenish on the edges; and is dissipated in grayish-white vapors, of a pungent smell, which condense into a white oxide. This oxide heated on charcoal is reduced with a kind of explosion, and soon again volatilised. Heated

in a glass retort it fuses into a straw-colored striated mass. It appears to contain about sixteen per cent. of oxygen.

Tellurium is oxidized and dissolved by the principal acids. To sulphuric acid it gives a deep purple color. Water separates it in black floculi, and heat throws it down in a white precipitate. With nitric acid it forms a colorless solution, which remains so when diluted, and affords slender dendritic crystals by evaporation. The muriatic acid, with a small portion of nitric, forms a transparent solution, from which water throws down a white submuriate. This may be redissolved almost wholly by repeated affusions of water. Alcohol likewise precipitates it.

Sulphuric acid, diluted with two or three parts of water, to which a little nitric acid has been added, dissolves a large portion of the metal, and the solution is not decomposed by water. The alkalis throw down from its solutions a white precipitate, which is soluble in all the acids, and by an excess of the alkalis or their carbonates. They are not precipitated by prussiate of potash. Tincture of galls gives a yellow flocculent precipitate with them. Tellurium is precipitated from them in a metallic state by zinc, iron, tin, and antimony.

Tellurium fused with an equal weight of sulphur, in a gentle heat, forms a lead colored striated sulphuret. Alkaline sulphurets precipitate it from its solutions of a brown or black color. In this precipitate either the metal or its oxide is combined with sulphur. Each of these sulphurets burns with a pale blue flame, and white smoke. Heated in a retort, part of the sulphur is sublimed, carrying up a little of the metal with it. It does not easily amalgamate with quicksilver.

TELLURETTED HYDROGEN, in chemistry, a gas formed by the combination of tellurium and hydrogen. To make this compound, hydrate of potash and oxide of tellurium are ignited with charcoal, and the mixture acted on by dilute sulphuric acid, in a retort connected with a mercurial pneumatic apparatus. An elastic fluid is generated, consisting of hydrogen holding tellurium in solution. It is possessed of very singular properties. It is soluble in water, and forms a claret-colored solution. It combines with the alkalis. It burns with a bluish flame, depositing oxide of tellurium. Its smell is very strong and peculiar, not unlike that of sulphureted hydrogen. This elastic fluid was discovered by Sir H. Davy in 1809. When tellurium is made the electrical negative surface in water, in the voltaic circuit, a brown powder is formed, which appears to be a solid combination of hydrogen and tellurium. It was first observed by Mr. Ritter in 1808. The composition of the gas and the solid hydruret has not been ascertained. The prime equivalent of tellurium, according to Sir H. Davy, is 4.93, reduced to the oxygen radix. Berzelius makes the oxide of tellurium a compound of metal 100 + oxygen 24.8. If we call the oxygen 25, then the atom or prime would be 4. In this case telluretted hydrogen, if analogous in its constitution to sulphuretted hydrogen, would have a specific gravity of 2.2916 (not 2.3074, as Dr. Thomson deduces it from the same data).

TELLUS, Lat., i. e. the earth, in the mythology, one of the Roman names of the goddess Cybele, and which in common language signified the same with terra, the earth; but in the mythology Terra was the name appropriated to the mother, the wife of Coelus, and Tellus to the daughter, the wife of Saturn. See Ops.

TEMENUS, a leader of the Heraclidæ, who became king of Argos. He was succeeded by Deiphon, who had married his daughter Hymetho.

TEMERA'RIOUS, *adj.* } Fr. *temeraire* ;
TEMER'ITY, *n. s.* } Latin *temerarius*.
 Rash; heady; unreasonably adventurous, or contemptuous of danger: the noun substantive corresponding.

The figures are bold even to temerity. *Cowley*.
 Resolution without foresight is but a temerarious folly; and the consequences of things are the first point to be taken into consideration. *L'Estrange*.

Should he find upon one single sheet of parchment an oration written full of profound sense, adorned with elegant phrase, the wit of man could not persuade him that this was done by the temerarious dashes of an unguided pen. *Ray*.

TEMESVAR, BANAT or BANNAT OF, a province in the south of Hungary, bounded by Transylvania, and by the rivers the Marosch, the Theyss, and the Danube. Its extent is about 9450 square miles; its population above 700,000. In the south-east it contains a range of high mountains, where pasturage and mining form the principal employment of its inhabitants; but the rest is level, and in many places marshy or sandy, though in general of great natural fertility. From the middle of the sixteenth century to 1716, this province was subject to the Turks, and had, under their management, become overrun with robbers; so that when the conquests of prince Eugene restored it to Austria, many parts of it were almost uninhabited: and the renewal of the Turkish war in 1737 ruined many of the European establishments. On the restoration of peace, however, a number of Servians, Rascians, Macedonians, and Bulgarians, repaired hither from the Turkish provinces, bringing their property along with them; and the new governor exerted himself with great zeal in the cause of improvement. In 1752 the government was changed from the military to the civil form, and, with the exception of a temporary check during the seven years' war, this province has gone on ever since in a gradual course of improvement.

TEMESVAR, a considerable town in the south of Hungary, the capital of the county of the same name, and one of the strongest fortresses of the Austrian empire. It stands at the confluence of the Temes and Rega, is well built for so backward a country, and contains a population of 11,000, a mixed race, of Rascian, German, and Greek origin. The chief public buildings are the cathedral, a Greek and a Catholic church, three monasteries, three hospitals, a synagogue, and extensive barracks for the garrison. The town is the residence both of a Catholic and of a Greek bishop. The chief manufacture is silk; but iron and woollens are also objects of traffic.

TEMESVAR, a frontier district of Hungary, in-

cluding the south and south-east parts of the bannat. On the west it is marshy, containing, however, fine and extensive plains; but in the east it is mountainous, with rich mines of copper. It is divided into the districts of German and Wallacho-Illyrian, and contains 173,000 inhabitants. The chief town is Pancsova, but the general's residence is at the town of Temesvar.

TEMESVAR, a palatinate of Hungary, occupying the central part of the bannat. Its area is 2460 square miles, with 244,000 inhabitants.

TEMPE, in ancient geography, a valley of Thessaly in Phthiotis, between Mount Olympus on the north, and Ossa on the south, through which the Peneus runs into the Ægean Sea. All the poets celebrate this valley as the most delightful spot on earth; with verdant walks, cool shady groves, and the melodious singing of birds, &c., and hence the name Tempe became proverbial for a pleasant spot. It was five miles long, but in some places not above an acre and a half broad. But Livy gives a quite different account of it, and says the Roman army were struck with horror in passing over the precipitous rocky chasm. Strabo accounts for the difference by the depredations of an earthquake. See Strabo ix. and Livy.

TEMPER, *v. a. & n. s.* } Fr. *temperer*; Lat. }
 TEMPERAMENT, *n. s.* } *tempero*. To mix so }
 TEMPERAMENTAL, *adj.* } that one part quali- }
 TEMPERANCE, *n. s.* } fies the other; com- }
 TEMPERATE, *adj.* } pound; bring to }
 TEMPERATELY, *adv.* } proper consistence }
 TEMPERATENESS, *n. s.* } or proportion: hence }
 TEMPERATURE, } to soften; mollify; }
 TEMPERED, *adj.* } govern: the noun }
 substantive means due mixture; middle course; mean constitution of body or mind; frame of mind; state to which certain metals are brought by art: temperament is also constitution; predominant disposition: the adjective corresponding: temperance, moderation; patience; calmness: temperate, moderate; unimpassioned: the adverb and noun substantive corresponding: temperature is natural constitution; degree of natural qualities; mediocrity; moderation: tempered is disposed in regard to the passions; adjusted, generally.

Prepare the sixth part of an ephah and the third part of an hin of oil, to temper with the fine flour.

Ezek. xlvi. 14.

Thy sustenance serving to the appetite of the eater, tempered itself to every man's liking.

Wisdom xvi. 21.

The potter tempering soft earth, fashioneth every vessel with much labour.

Id. xv. 7.

His senseless speech and doted ignorance
 When as the noble prince had marked well,
 He calmed his wrath with goodly temperance.

Spenser.

Solon, in his laws to the Athenians, laboured to temper their warlike courage with sweet delights of learning and sciences: so that as much as the one excelled in arms, the other exceeded in knowledge.

Spenser on Ireland.

In that proud port, which her so goodly graceth,
 Most goodly temperature you may descry.

Spenser.

With which the damned ghosts he governeth,
 And furies rules, and Tartare tempereth.

Id.

When was my lord so much ungently tempered,
 To stop his ears against admonishment?

Shakspeare.

If you could find out but a man
 To bear a poison, I would temper it;
 That Rome should upon receipt thereof
 Soon sleep in quiet.

Id.

She's not forward, but modest as the dove:
 She is not hot, but temperate as the morn.

Id.

What! are you chafed?

Ask God for temperance, that's the appliance only
 Which your disease requires.

Id. Henry VIII.

Now will I to that old Andronicus,
 And temper him with all the art I have.

Shakspeare.

Here draw I

A sword, whose temper I intend to stain
 With the best blood that I can meet withal.

Id.

The brain may devise laws for the blood, but a
 hot temper leaps over a cold decree.

Id. Merchant of Venice.

Temperately proceed to what you would

Thus violently redress.

Shakspeare.

Nothing better proveth the excellency of this soil
 and temper than the abundant growing of the palm
 trees.

Raleigh.

Use a temperate heat; for they are ever temperate
 heats that digest and mature; wherein we mean
 temperate, according to the nature of the subject; for
 that may be temperate to fruits and liquors, which
 will not work at all upon metals.

Bacon.

Birds that change countries at certain seasons, if
 they come earlier, shew the temperature of the weather.

Id.

As the world's sun doth effects beget
 Different in divers places every day;
 Here autumn's temperate, there summer's heat,
 Here flowery spring-tide, and there winter grey.

Davies.

Restore yourselves unto your tempers, fathers,
 And without perturbation hear me speak.

Ben Jonson.

It lieth in the same climate, and is of no other
 temperature than Guinea.

Abbot's Description of the World.

Langley's mild temperateness

Did tend unto a calmer quietness.

Daniel's Civil War.

This, I shall call it evangelical, temper is far from
 being natural to any corrupt child of Adam.

Hammond.

God esteems it a part of his service if we eat or
 drink; so it be temperately, and as may best preserve
 health.

Taylor.

His sleep

Was airy, light, from pure digestion bred,
 And temperate vapours bland.

Milton.

Observe

The rule of thou too much; by temperance taught
 In what thou eatest and drinkest; seeking from
 thence

Due nourishment, not glutinous delight.

Id.

These soft fires with kindly heat

Of various influence foment and warm,

Temper or nourish.

Id.

The sword

Of Michael from the armoury of God
 Was given him tempered so, that neither keen
 Nor solid might resist that edge.

Id.

Remember with what mild
 And gracious temper he both heard and judged,
 Without wrath or reviling.

Id. Paradise Lost.

The common law has wasted and wrought out those
 distempers, and reduced the kingdom to its just state
 and temperment.

Hale.

Intellectual representations are received with as

unequal a fate, upon a bare *temperamental* relish or disgust.

Glanville.

From *temperate* inactivity we are unready to put in execution the suggestions of reason.

Browne's Vulgar Errors.

That *temperamental* dignotions, and conjecture of prevalent humours, may be collected from spots in our nails, we concede.

Id.

There may be as much difference as to the *temperature* of the air, and as to the heat and cold, in one mile, as in ten degrees of latitude; and he that would cool and refresh himself in the summer, had better go up to the top of the next hill, than remove into a far more northern country. *Id. Travels.*

Woman! Nature made thee

To *temper* man: we had been brutes without you.

Otway.

In the *tempering* of steel, by holding it but a minute or two longer or lesser in the other competent heat, gives it very different *temper*s as to brittleness or toughness.

Boyle.

Temperance, that virtue without pride, and fortune without envy, gives indolence of body and tranquillity of mind; the best guardian of youth and support of old age.

Temple.

Repeated peals they hear,

And, in a heaven serene, refulgent arms appear:

Reddening the skies, and glittering all around,

The *tempered* metals clash, and yield a silver sound.

Dryden.

This will keep their thoughts easy and free, the only *temper* wherein the mind is capable of receiving new informations.

Locke on Education.

Bodies are denominated hot and cold, in proportion to the present *temperament* of that part of our body to which they are applied.

Locke.

This body would be increased daily, being supplied from above and below; and, having done growing, it would become more dry by degrees, and of a *temper* of greater consistency and firmness.

Burnet's Theory of the Earth.

The good old knight, with a mixture of the father and master of the family, *tempered* the inquiries after his own affairs with kind questions relating to themselves.

Addison.

By winds that *temperately* blow,

The bark should pass secure and slow. *Id.*

If, instead of this variation of heat, we suppose an equality or constant *temperature* of it before the deluge, the case would be much altered.

Woodward's Natural History.

Health itself is but a kind of *temper*, gotten and preserved by a convenient mixture of contraries.

Arbutnot.

These needles should have a due *temper*; for, if they are too soft, the force exerted to carry them through the flesh will bend them; if they are too brittle, they snap.

Sharp.

I advised him to be *temperate* in eating and drinking.

Wiseman.

Teach me, like thee, in various nature wise,

To fall with dignity, with *temper* rise. *Pope.*

If the estates of some bishops were exorbitant before the reformation, the present clergy's wishes reach no further than that some reasonable *temper* had been used, instead of paring them so quick.

Swift's Miscellanies.

Memory depends upon the consistence and the *temperature* of the brain.

Watts.

All irregular *temper*s in trade and business are but like irregular *temper*s in eating and drinking. *Law.*

TEMPERAMENT, among physicians, is a certain disposition of the solids and fluids of the human body, by which it may be properly denominated

strong, weak, lax, &c. In every person there is perhaps a temperament peculiar to himself, though the ancients only took notice of four, which indeed seem to have a real existence, and are capable of receiving an explanation. The two that are most distinctly marked are the sanguineous and melancholic, viz. the temperaments of youth and age. 1. Sanguineous.—Here there is laxity of solids, discoverable by the softness of hair and succulency; large system of arteries, redundancy of fluids, florid complexion; sensibility of the nervous power, especially to pleasing objects; irritability from the plethora; mobility and levity from lax solids. 2. Melancholic habit.—Here greater rigidity of solids occurs, discoverable by the hardness and crispature of the hair; small proportion of the fluids, hence dryness and leanness; small arteries, hence pale color; venous plethora, hence turgescency of these, and lividity; sensibility, frequently exquisite; moderate irritability, with remarkable tenacity of impressions; steadiness in action and slowness of motion, with great strength; for excess of this constitution in maniacs gives the most extraordinary instance of human strength we know. This temperament is most distinctly marked in old age, and in males. 3. The choleric temperament takes place between youth and manhood. In this the distribution of the fluids is more exactly balanced; there is less sensibility, and less obesity, with more irritability, proceeding from greater tension, less mobility and levity, and more steadiness in the strength of the nervous power. As to the 4. Phlegmatic, it cannot be distinguished by any characters of age or sex. It agrees with the sanguineous in laxity and succulency. It differs from that temperament and the melancholic, by the more exact distribution of the fluids. Again it differs from the sanguineous, by having less sensibility, irritability, mobility, and perhaps strength, though sometimes indeed this last is found to be great. These are the ancient temperaments. The temperaments indeed are much more various; and very far from being easily marked and reduced to their genera and species, from the great variety which is observable in the constitutions of different men. But the late Dr. Brown, among other bold assertions, insisted that there is no natural difference of constitution but what is occasioned by habit and accident.

TEMPERAMENT, in music, is defined by Rousseau to be an operation, which, by a slight alteration in the intervals, causes the difference between two contiguous sounds to disappear, makes each of these sounds seem identical with the other, which, without offending the ear, may still preserve their respective intervals or distances one from the other. By this operation the scale is rendered more simple, and the number of sounds which would otherwise be necessarily retrenched. Had not the scale been thus modified, instead of twelve sounds alone, which are contained in the octave, more than sixty would be indispensably required to form what we properly call modulation in every tone. See Music.

TEMPERING, in the mechanic arts, the preparing of steel and iron, so as to render them

more compact, hard, and firm; or more soft and pliant, according to their respective occasions.

See IRON and STEEL.

TEMPEST. *n. s. & v. a.* } French *tempeste* ;
 TEMP'ESTBEATEN, *adj.* } Lat. *tempestas*. The
 TEMP'ESTTOST, } utmost violence of
 TEMPESTIV'ITY, *n. s.* } the wind: to dis-
 TEMPESTUOUS, *adj.* } turbul by a tempest.

'The names,' says Johnson, 'by which the wind is called according to the gradual increase of its force seem to be, a breeze; a gale; a gust; a storm; a tempest: any commotion or storm: the two compounds following are of obvious meaning: tempestivity is a Latinism only used, as we find, by Brown for seasonableness: tempestuous is stormy; turbulent.

Tempestuous fortune hath spent all her spite,
 And thrilling sorrow thrown his utmost dart.

Spenser.

I have seen *tempests*, when the scolding winds
 Have rived the knotty oaks.

Shakspeare. Julius Cæsar.

The *tempest* in my mind

Doth from my senses take all feeling else,
 Save what beats there.

Id. King Lear.

Though his bark cannot be lost,

Yet it shall be *tempest-tost.* *Id. Macbeth.*

What at first was called a gust, the same

Hath now a storm's, anon a *tempest's* name. *Donne.*

Some have been driven by *tempest* to the south.

Abbot.

Part huge of bulk,

Wallowing unwieldy, enormous in their gait,

Tempest the ocean. *Milton.*

We, caught in a fiery *tempest*, shall be hurled

Each on his rock transfixed. *Id.*

Which of them rising with the sun, or falling,

Should prove *tempestuous.* *Id.*

Since their dispersion, the constitutions of coun-
 tries admit not such *tempestivity* of harvest.

Brown's Vulgar Errors.

In the calm harbour of her gentle breast,

My *tempest-beaten* soul may safely rest.

Dryden's Aurengzebe.

Her looks grow black as a *tempestuous* wind,

Some raging thoughts are rowling in her mind.

Dryden.

Pompey, when dissuaded from embarking because

the weather was *tempestuous*, replied, My voyage is

necessary, my life is not so.

Collier on the Value of Life.

With clouds and storms

Around thee thrown, *tempest* o'er *tempest* rolled,

Thou humblest nature with thy northern blast.

Thomson.

TEMPESTA (Antony), an Italian painter,

born at Florence in 1555. He studied under

Strada, and excelled in landscapes with figures.

He also engraved some prints. He died in 1630.

TEMP'LAR, *n. s.* } From the Temple, a

TEMP'LE. } house near the Thames,

anciently belonging to the knights templars, ori-

ginally from the temple of Jerusalem. French,

temple; Lat. *templum*. A student in the law:

a building devoted to divine worship or to acts

of religion.

The honoured gods

Throng our large *temples* with the shews of peace.

Shakspeare.

Most sacrilegious murder hath broke ope

The Lord's anointed *temple*, and stole thence

The life o' the' building. *Id. Macbeth.*

Wits and *templars* every sentence raise,
 And wonder with a foolish face of praise.

Pope's Epistle.

TEMPLARS, TEMPLERS, or knights of the temple, a religious order instituted at Jerusalem in the beginning of the twelfth century, for the defence of the holy sepulchre, and the protection of Christian pilgrims. They were first called the poor of the holy city, and afterwards assumed the appellation of templars, because their house was near the temple. The order was founded by Baldwin II., king of Jerusalem, with the concurrence of the pope: and the principal articles of their rule were:—That they should hear the holy office throughout every day; or that, when their military duties should prevent this, they should supply it by a certain number of pater noster; that they should abstain from flesh four days in the week, and on Fridays from eggs and milk meats; that each knight might have three horses and one esquire; and that they should neither hunt nor fowl. After the ruin of the kingdom of Jerusalem, about 1186, they spread themselves through Germany and other countries of Europe, to which they were invited by the liberality of the Christians. In 1228 this order acquired stability, by being confirmed in the council of Troyes, and subjected to a rule of discipline, drawn up by St. Bernard. In every nation they had a particular governor, called master of the temple, or of the militia of the temple. Their grand master resided at Paris. The order flourished for some time, and acquired, by the valor of its knights, immense riches and an eminent degree of military renown; but, as their prosperity increased, their vices multiplied, and their arrogance, luxury, and cruelty, rose at last to such a monstrous height, that their privileges were revoked, and their order suppressed, with the most terrible circumstances of infamy and severity. Their accusers were two of their own body, and their chief prosecutor Philip the Fair of France, who addressed his complaints to Clement V. The pope, though at first unwilling to proceed against them, was under a necessity of complying with the king's desire; so that, in 1307, upon an appointed day, and for some time afterwards, all the knights who were dispersed throughout Europe, were seized and imprisoned, and many of them, after trials for capital crimes, were convicted and put to death. In 1312 the whole order was suppressed by the council of Vienna. A part of the rich revenues they possessed was bestowed upon other orders, especially on the knights of St. John, now of Malta, and the rest confiscated to the respective treasuries of the sovereign princes in whose dominions their possessions lay.

TEMPLE (Sir William), an eminent statesman, born in London in 1628. His family was ancient, and assumed the surname of Temple from the manor of temple, in the hundred of Sparken Hall, Leicestershire. He was first sent to Pensehurst, in Kent, under his uncle, Dr. Hammond; but at ten he was removed to Bishop's Stortford, in Hertfordshire. In his seventeenth year he went to Cambridge, where he was placed under the tuition of Dr. Cudworth. After

acquiring a competency of French and Spanish, he was sent abroad to finish his education. Having resided two years in France, Mr. Temple made a tour through Holland, Flanders, and Germany. In 1654 he returned home, and married Miss Osborn, daughter of Sir Peter Osborn, of Chicksand. He rejected all offers of employment under Cromwell; but at the restoration, in 1690, being chosen a member of the Irish convention, while others were trying to make their court to the king, Mr. Temple opposed the poll-bill with so much spirit that his conduct soon attracted the attention of the public, and brought him into notice. In the next parliament, in 1661, he was elected with his father for the county of Carlow; and in 1662 was chosen one of the commissioners from that parliament to the king. Soon after he went back to Ireland, where he met with a very favorable reception from the duke of Ormond. In 1665 he was sent with a secret commission to the bishop of Munster, which he executed so much to the satisfaction of Charles II. that on his return to Brussels he appointed him resident there, and created him a baronet. In April 1666 he sent for his family; but, before their arrival, he had been again obliged to depart upon business to the prelate's court. Having finished his business at Munster he returned to Brussels, where he passed a year. In spring 1667, a new war breaking out between France and Spain, which exposed Brussels to danger, Sir William sent his lady and family to England; but he himself remained there with his sister till December 25th, when he was ordered by the king to come over privily to London. Taking the Hague in his way, he paid a visit to De Witt, and proposed those overtures which produced the triple alliance. Soon after his arrival at the British court, he returned, on the 16th of January, 1668, with the character of envoy extraordinary and plenipotentiary to Holland; where a conference being opened, he brought that treaty to a perfect conclusion in five days. The ratifications of this alliance being exchanged on the 15th of February, he repaired to Brussels; and a treaty being set on foot between France and Spain at Aix-la-Chapelle, he set out for that place on the 24th of April in quality of his majesty's ambassador extraordinary. He arrived on the 27th; and it was chiefly owing to his assistance that the Spaniards were brought to sign the articles of that peace on the 2d of May. He then returned to Brussels, with a view of remaining there in his former station of resident; but he received letters from the earl of Arlington, with the king's order to be his ambassador. Sir William upon this returned to England, and was received with every possible token of favor by the king. Setting out again for Holland, in his new character of ambassador, he arrived at the Hague in August, 1668; where he enjoyed the confidence of that great minister De Witt, and lived in great intimacy with the prince of Orange, then only eighteen years of age; but in September, 1669, he was hurried back to England by lord Arlington, and pressed to return to the Hague, and pave the way for a war with Holland.

This, however, he refused to have any hand in; which so much provoked the lord treasurer Clifford that he refused to pay him an arrear of £2000 due from his embassy. Disgusted with Arlington's behaviour, Sir William returned to his house at Sheen, near Richmond, in Surrey. About the end of summer, however, 1673, the king, wishing to put an end to the war, sent for Sir William to negotiate a peace; but, powers having been sent from Holland to the marquis de Fresno, the Spanish ambassador at London, Sir William was ordered to confer with him; and a treaty was concluded in three days, and the point carried respecting the superiority of the British flag, which had been so long contested. In June 1674 he was again sent ambassador to Holland to offer the king's mediation between France and the confederates, then at war, which was accepted soon after; lord Berkeley, Sir William Temple, and Sir Leoline Jenkins, being declared ambassadors and mediators; Nimeguen, which Sir William had proposed, was at length agreed upon by all parties to be the place of treaty. During his stay at the Hague, the prince of Orange, who was fond of the English language, constantly dined and supped once or twice a-week at his house; and by this familiarity he so much gained the prince's confidence and esteem, that he had a considerable hand in his marriage with the princess Mary, daughter of James II. In July, 1676, he removed his family to Nimeguen, and in 1677 his son was sent over with letters ordering him to return, and succeed Mr. Coventry as secretary of state. In consequence of this order, Sir William came over to England in spring 1677; and, though the affair of the secretaryship was dropped at his desire, he did not return to Nimeguen that year. About this time the prince of Orange came over, and married the princess Mary; and this gave occasion for a new coolness between lord Arlington and Sir William, as he and the lord treasurer Osborn, who was related to Sir William's lady, were only privy to that affair. After the prince and princess were gone to Holland, as the court seemed inclined to favor France, the king wished to engage Sir William in some negotiations with that crown; but he was so ill satisfied with this proposal, that he offered to give up all pretensions to the office of secretary; and, desiring the lord treasurer to acquaint his majesty with his intentions, retired to Sheen, in hopes of being taken at his word. Upon a discovery, however, of the French designs not to evacuate the Spanish towns agreed by the treaty to be delivered up, the king commanded him to go upon a third embassy to the states; with whom he concluded a treaty; by which England engaged, in case France refused to evacuate the towns in forty days, to declare war immediately against that nation; but, before half that time was elapsed, one Du Cross was sent from the English court to Holland upon a business which damped all the good humor excited by the treaty there, and which produced such sudden changes here as gave Sir William a distaste for all public employments. In 1679 he went back to Nimeguen, where the French delayed to sign the treaty till the last hour; but,

having concluded it, he returned to the Hague, whence he was soon after sent for to enter upon the secretary's office, which Mr. Coventry at length resolved to resign. He accordingly came over and went to court, with a full intention of assuming his office; but he started a difficulty that he had not a seat in the house of commons; and, notwithstanding the king's repeated intreaties, refused to accept, but advised him to choose a council in whom he could confide, and upon whose abilities he could depend. This advice was followed, and, the choice of the persons being concerted between the king and Sir William, the old council was dissolved four days after, and the new one established, of which Sir William was a member. In 1680 the council began again to be changed on the king's illness, at the end of the summer, and the duke of York returned privately to court. In this juncture Sir William, endeavouring to restore to the king's favor some persons to whom he had taken a dislike, he met with such treatment as gave him a fresh distaste to the court; so that he resided principally at Sheen. Soon after this the king sent for him again; and, having proposed that he should go as ambassador into Spain, Sir William consented; but when his equipage was almost ready, and part of the money paid down for it, the king proposed to defer his journey till the end of the session of parliament, in which he was chosen a member for the university of Cambridge. In this session the spirit of party ran so high that it was impossible to bring the house to any temper. The duke was sent into Scotland; but nothing would satisfy them but a bill of exclusion, which Sir William strenuously opposed. Not long after this period, the parliament being dissolved by the king, without the advice of his privy council, and contrary to his promise, Sir William made a bold speech against it; for which he was very ill used by some of those who had been most earnest in promoting the last change in the ministry. Upon this he grew quite tired of public business, declined the offer he had of again serving for the university in the next parliament, that soon after met at Oxford; and, seeing the king resolved to govern without his parliament, and to supply his treasury through another channel, he retired to Sheen, resolving never more to meddle with public affairs. From that time Sir William lived at this place, till, having purchased a seat, called Moor-Park, near Farnham in Surrey, which he conceived a great fondness for, he resolved to spend the remainder of his life in this agreeable retreat. At the time of the revolution, in 1688, Moor-Park becoming unsafe, as it lay in the way of both armies, he went back to the house at Sheen, which he had given up to his son. When the prince reached Windsor, he went thither to wait upon his highness, and carried his son along with him. The prince pressed him to enter into his service, and to be secretary of state; but, his age and infirmities confirming him in the resolution he had made not to meddle any more with public affairs, he was satisfied that his son alone should enjoy his majesty's favor. Mr. John Temple was appointed secretary at war; but he had

hardly been a week in that office when he drowned himself. In 1694 Sir William lost his lady. After this he lived four years, very much afflicted with the gout; and died in January 1698. His body was interred in Westminster Abbey, and a marble monument erected in 1722. Sir William's principal works are, 1. Memoirs from 1672 to 1692. 2. Remarks upon the State of the United Provinces. 3. An Introduction to the History of England. 4. Letters written during his last embassies: and, 5. Miscellanies, which contain many curious pieces. He was an accomplished gentleman, a sound politician, a patriot, and a scholar.

A TEMPLE is a public building erected in honor of some deity, either true or false; and wherein the people meet to pay religious worship. The word is formed from the Latin *templum*, the Greek *τεμενος*, signifying the same thing; from *τεμνω*, I separate, as a temple is a place separated from common uses. Others with more probability derive it from the old Latin word *templare*, to contemplate. It is certain the ancient augurs gave the name *templa* to those parts of the heavens which were marked out for the observation of the flight of birds. Their formula was, *Templa tesqua sunt*. Temples were originally all open, and hence received their name. See Philosophical Transactions No. 471, sect. 5, where we have an account of an ancient temple in Ireland of the same sort as Stonehenge.

Templum, among the old Romans, signified a place consecrated by the augurs, whether enclosed or open, in the city or in the fields. Clemens Alexandrinus and Eusebius refer the origin of temples to the sepulchres built for the dead. This notion has been lately illustrated and confirmed by Mr. Farmer in his Treatise on the Worship of Human Spirits, p. 373, &c. Herodotus and Strabo say, the Egyptians were the first who built temples to the gods. The first erected in Greece is ascribed to Deucalion, by Apollonius, Argonaut. lib. iii. The Druids and others of the ancients performed their sacrifices in all places indifferently, from a persuasion that the whole world is the temple of God, and that he required no other. This was the doctrine of the magi, followed by the Persians, the Scythians, the Numidians, and many other nations mentioned by Herodotus, lib. i, Strabo, lib. xv, and Cicero in Verrem. 2. The Romans had several kinds of temples; whereof those built by the kings, &c., consecrated by the augurs, and wherein the exercise of religion was regularly performed, were called, by way of eminence, *templa*. Those that were not consecrated were called *ædes*. The little temples, that were covered or roofed, they called *ædicule*. Those open *pacella*. Some other edifices, consecrated to particular mysteries, they called *fana* and *delubra*. The most celebrated temples among the Romans were the Capitol and Pantheon. They had also the temple of Saturn, which served for the public treasury; and the temple of Janus. The Indian temples, or pagodas, are sometimes of a prodigious size. They are commonly erected near the banks of the Ganges, Kistna, or other sacred rivers, for the benefit of ablutation in the purifying stream. Where no river

flows near the foot of the pagoda, there is invariably in the front of it a large tank or reservoir of water. These are, for the most part, of a quadrangular form, are lined with freestone or marble, have steps regularly descending from the margin to the bottom, and Mr. Crauford observed many between 300 and 400 feet in breadth. At the entrance of all the more considerable pagodas there is a portico, supported by rows of lofty columns, and ascended by a handsome flight of stone steps; sometimes, as in the instance of Tripetti, to the number of more than a hundred. Under this portico, and in the courts that generally enclose the whole building, an innumerable multitude assemble at the rising of the sun; and, having bathed in the stream below, and, in conformity to an immemorial custom over all the east, having left their sandals on the border of the tank, impatiently await the unfolding of the gates by the ministering brahmin. The gate of the pagoda universally fronts the east, to admit the rays of the solar orb; and, opening, presents to the view an edifice partitioned out, according to M. Thevenot in his account of Chitanagar, in the manner of the ancient cave temples of Elora, having a central nave or body; a gallery ranging on each side; and, at the farther end, a sanctuary, or chapel of the deity adored, surrounded by a stone balustrade to keep off the populace. Those who wish to peruse a more particular account of the Indian temples may consult Maurice's Indian Antiquities. See also PAGODA and SERINGHAM.

The TEMPLE AT JERUSALEM was similar in its plan to the tabernacle. The first temple was begun by Solomon about A. M. 2992, and A. A. C. 1012, and finished in eight years. It consisted of the holy of holies, the sanctuary, and a portico. The holy of holies was a square room of twenty cubits; the sanctuary, or holy place, was forty cubits long, and twenty broad, consequently the length of both these together was sixty cubits. The portico, which stood before the sanctuary, was twenty cubits long, and ten broad. The whole length of the temple, computing the cubit at twenty-two inches, did not exceed 110 feet in length, and thirty-six feet eight inches in breadth. In the portico stood the two brazen pillars called Jachin and Boaz, which appear to have been forty cubits high, and about four in diameter. The court about the tabernacle was 100 cubits long, and fifty broad; and, as Solomon made every part of the temple about twice as large as the corresponding part in the tabernacle, we may conclude, that the court around the temple was 200 cubits long, and 100 broad. According to this description, the temple of Solomon was by no means so large as it is commonly represented. Still, however, it was very magnificent in size, and splendid in ornament. It was plundered of its treasures in the reign of Rehoboam, and repaired by Joash; it was again spoiled in the time of Ahaz and of Hezekiah; and, after being restored by Josiah, was demolished by Nebuchadnezzar in A. M. 3416, after it had stood 476 years according to Josephus, and, according to Usher, 428 years. The second temple was built by the Jews, after their return from the Babylonish captivity, under

the direction of Zerubbabel their governor, and of Joshua the high priest, with the encouragement of Cyrus the Great to whom Judea was become a tributary kingdom. This temple was destitute of five remarkable appendages, which were the chief glory of the first temple; viz. the ark and mercy-seat, the shechinah, the holy fire on the altar, which had been first kindled from heaven, the urim and thummim, and the spirit of prophecy. This temple was plundered and profaned by Antiochus Epiphanes (see JEWS), but afterwards purified by Judas Maccabeus, who restored the divine worship; and, after having stood 500 years, rebuilt by Herod, with a magnificence approaching to that of Solomon's. Tacitus calls it *immensæ opulentæ templum*; and Josephus says, it was the most astonishing structure he had ever seen, as well on account of its architecture as its magnitude, and the richness and magnificence of its various parts and sacred appurtenances. This temple, which Herod began to build about sixteen years before the birth of Christ, and so far completed in nine years and a half as to be fit for divine service, was at length destroyed by the Romans on the same month and day of the month on which Solomon's temple was destroyed by the Babylonians.

TEMPLES, in architecture. The ancient temples were distinguished, with regard to their construction, into various kinds; as *templum in antis*, or *Ædes in antis*. These, according to Vitruvius, were the most simple of all temples, having only angular pilasters, called *antæ* or *parastatæ*, at the corners, and two Tuscan columns on each side of the doors. Temple, *tetrastyle*, or simply *tetrastyle*, was a temple that had four columns in front, and as many behind. Such was the temple of Fortuna Virilis at Rome. Temple, *prostyle*, that which had only columns in its front or fore-side; as that of Ceres at Eleusis in Greece. Temple, *amphiprostyle*, or *doublé prostyle*, that which had columns both before and behind, and which was also *tetrastyle*. Temple, *periptere*, that which had four rows of insulated columns around, and was *hexastyle*, i. e. had six columns in front; as the temple of Honor at Rome. Temple, *diptere*, that which had two wings, and two rows of columns around, and was also *ostostyle*, or had eight columns in front; as that of Diana at Ephesus.

TEMPLES, *n. s.* Lat. *tempora*. The upper part of the sides of the head where the pulse is felt.

Her sunny locks

Hang on her temples like a golden fleece.

Shaks e. re.

The weapon entered close about his ear,
Cold through his temples glides the whizzing spear.

Pope.

We may apply intercipients of mastich upon the temples; frontals also may be applied.

Wiseman's Surgery.

To procure sleep, he uses the scratching of the temples and ears; that even mollifies wild beasts.

Arbuthnot.

TEMPLES, in anatomy, a double part of the head, reaching from the forehead and eyes to the two ears. The temples are chiefly formed of two bones called *ossa temporis*. These parts, accord

ing to physicians, were called tempora, from their showing the age or time of a man by the color of the hair, which turns white in this part before any other; which Homer seems to have been aware of, by his calling men poliocrotaphi, i. e. gray templesd.

TEMPLES also denote two inns of court in London, thus called, because anciently the dwelling-house of the knights-templars. At the suppression of that order, they were purchased by the professors of the common law, and converted into hospitia or inns. They are called the inner and middle temple, in relation to Essex-house; which was also a part of the house of the templars, and called the outer temple, because situated without Temple Bar. In the middle temple, during the time of the templars, the king's treasure was kept; as was also that of the kings of France in the house of the templars at Paris. The chief officer was the master of the temple, who was summoned to parliament in 47 Hen. III.; and from him the chief minister of the temple church is still called master of the temple.

TEMPLET, *n. s.* A diminutive of temple. A piece of timber in a building.

When you lay any timber on brick-work, as lintels over windows, or *templets* under girders, lay them in loom. *Moxon's Mechanical Exercises.*

TEMPORAL, *adj.* Fr. *temporal*; low. TEMPORALITY, *n. s.* Lat. *temporalis*. Measured by time; not eternal; not spiritual; placed at the temples: TEMPORARY, *adj.* temporality and temporals mean temporal or secular possessions: temporality, the laity; secular people: temporary, lasting only for a limited time.

As there they sustain *temporal* life, so here they would learn to make provision for eternal. *Hooker.*

All the *temporal* lands which men devout

By testament have given to the church,
Would they strip from us. *Shakspeare. Henry V.*

Call not every *temporal* end a defiling of the intention, but only when it contradicts the ends of God, or when it is principally intended: for sometimes a *temporal* end is part of our duty; and such are all the actions of our calling. *Taylor.*

The residue of these ordinary finances is casual, as the *temporalities* of vacant bishopricks, the profits that grow by the tenures of lands. *Bacon.*

These *temporary* truces were soon made and soon broken; he desired a straighter amity. *Id. Henry VII.*

The pope sucked out inestimable sums of money, to the intolerable grievance of clergy and *temporality*. *Abbot.*

If the Lord's immediate speaking, uttering, and writing, doth conclude, by a necessary inference, that all precepts uttered and written in this manner are simply and perpetually moral; then, on the contrary, all precepts wanting this are merely *temporary*. *White.*

There is scarce any of those decisions but gives good light, by way of authority or reason, to some questions that arise also between *temporal* dignities, especially to cases wherein some of our subordinate *temporal* titles have part in the controversy. *Selden.*

Such revenues, lands, and tenements, as bishops have had annexed to their sees by the kings and others from time to time, as they are barons and lords of the parliament. *Cowell.*

Sinners, who are in such a *temporarily* happy con-

dition, owe it not to their sins, but wholly to their luck. *South.*

The king yielded up the point, reserving the ceremony of homage from the bishops, in respect of the *temporalities*, to himself. *Ayliffe.*

The republick, threatened with danger, appointed a *temporary* dictator, who, when the danger was over retired again into the community. *Addison.*

Prayer is the instrument of fetching down all good things to us, whether spiritual or *temporal*.

Duty of Man.
Our petitions to God, with regard to *temporals*, must be that medium of convenience proportioned to the several conditions of life. *Rogers's Sermons.*

Copious bleedings, by opening the *temporal* arteries, are the most effectual remedies for a phrensy. *Arbuthnot on Aliments.*

All *temporal* power hath been wrested from the clergy, and much of their ecclesiastick. *Swift.*

TEMPORAL ARTERIES, the arteries of the temples. See ANATOMY, INDEX, and TEMPLES.

TEMPORALTY. Those of bishops are the revenues, lands, tenements, and lay fees, belonging to bishops, as they are barons and lords of parliament. The custody of the *temporalities* of bishops forms a branch of the king's ordinary revenues. These, upon the vacancy of the bishopric, are immediately the right of the king, as a consequence of his prerogative in church matters; whereby he is considered as the founder of all archbishoprics and bishoprics, to whom, during the vacancy, they revert. This revenue of the king, which was formerly very considerable, is now by a customary indulgence almost reduced to nothing: for, at present, as soon as the new bishop is consecrated and confirmed, he usually receives the restitution of his *temporalities* quite entire and untouched from the king; and then, and not sooner, he has a fee-simple in his bishopric, and may maintain an action for the profits.

TEMPORIZE, *v. n.* } Fr. *temporiser*; Lat. TEMPORIZER, *n. s.* } *tempus*. To delay; procrastinate; comply with the times; compound: the noun substantive corresponds.

If Cupid hath not spent all his quivers in Venice, thou wilt quake for this shortly.

—I look for an earthquake too then.

—Well, you will *temporise* with the hours.

Shakspeare.

The dauphin is too wilful opposite,
And will not *temporize* with my entreaties:
He flatly says, he'll not lay down his arms. *Id.*

I pronounce thee a hovering *temporizer*, that
Canst with thine eyes at once see good and evil,
Inclining to them both. *Id. Winter's Tale.*

The earl of Lincoln, deceived of the country's course, in which case he would have *temporised*, resolved to give the king battle. *Bacon's Henry VII.*

They might their grievance inwardly complain,
But outwardly they needs must *temporize*. *Daniel.*

TEMPT, *v. a.* } Fr. *tenter*; Lat. *tento*. TEMPTABLE, *adj.* } To incite; entice; solicit TEMPTATION, *n. s.* } to ill; try; attempt: TEMPTER. } the adjective and noun substantives corresponding.

Come together, that Satan *tempt* you not.

1 Cor. vii. 5.

'Tis not the king that sends you to the Tower:
My lady Gray *tempts* him to this harsh extremity.

Shakspeare.

I'm much too vent'rous
In *tempting* of your patience. *Id. Henry VIII.*
Set a deep glass of rhenish wine on the contrary
casket ; for if the devil be within, and that *temptation*
without, he will chuse it. *Id. Merchant of Venice.*
Is this her fault or mine ?
The *tempter* or the *tempted*, who sins most ?
Not she ; nor doth she *tempt*.

Id. Measure for Measure.
The experience of our own frailties, and the watch-
fulness of the *tempter*, discourage us.

Hammond's Fundamentals.
When by human weakness and the arts of the
tempter, you are led into *temptations*, prayer is the
thread to bring you out of this labyrinth. *Dappa.*

He that hath not wholly subdued himself, is
quickly *tempted* and overcome in small things.

Bishop Taylor.
Fixed on the fruit she gazed, which to behold
Might *tempt* alone. *Milton.*

Still his strength concealed
Which *tempted* our attempt, and wrought our fall. *Id.*
All *temptation* to transgress repel. *Id.*

Foretold what would come to pass,
When first this *tempter* crossed the gulf from hell. *Id.*

Those who are bent to do wickedly will never want
tempters to urge them on. *Tillotson.*

Withhold
Your talons from the wretched and the bold ;
Tempt not the brave and needy to despair ;
For, though your violence should leave 'em bare
Of gold and silver, swords and darts remain. *Dryden.*

This from the vulgar branches must be torn,
And to fair Proserpine the present born,
Ere leave be given to *tempt* the nether skies. *Id.*
Dare to be great without a guilty crown ;
View it and lay the bright *temptation* down :
'Tis base to seize on all. *Id. Aurengzebe.*

My work is done :
She's now the *tempter* to ensnare his heart. *Dryden.*
The devil can but *tempt* and deceive ; and, if he
cannot destroy so, his power is at an end. *South.*

O wretched maid !
Whose roving fancy would resolve the same
With him who next should *tempt* her easy fate. *Prior.*

The roving crew,
To *tempt* a fair clothe all their tilts in blue. *Gay.*
If the parliament were as *temptable* as any other
assembly, the managers must fail for want of tools to
work with. *Swift.*

TEMSENA, a province in the empire of Mo-
rocco, bordering on the Atlantic, is very pro-
ductive in corn, and abounds in cattle. The
best cavalry in the empire are found in this pro-
vince. The men are a strong, robust, copper
race, while the women possess a great share of
beauty. The very name is said to signify the
salubrity of the air, being derived from the two
words Tamam Sana, 'once a year,' to express
that such a residence is sufficient to restore health
to the invalid. In the forests is found a kind of
resinous cedar, a remarkably hard and incor-
ruptible wood. The inhabitants of this province,
with that of Shawia, which is contiguous, and
closely connected, are stated by Mr. Jackson at
1,160,000.

TEN, *adj.* Sax. *tȳn* ; Goth. and Belg. *tien*.
The decimal number ; twice five, the number by
which we multiply numbers into new denomi-
nations ; a proverbially large number.

Thou shalt have more
'Than two *tens* to a score. *Shakspeare. King Lear.*
Ten hath been extolled as containing even, odd,
long, and plain, quadrate and cubical numbers ; and
Aristotle observed, that Barbarians as well as Greeks
used a numeration unto *ten*.

Browne's Vulgar Errors.
With twice *ten* sail I crossed the Phrygian sea,
Scarce seven within your harbour meet. *Dryden.*

There's a proud modesty in merit,
Averse from begging ; and resolved to pay
Ten times the gift it asks. *Id. Cleomenes.*

From the soft lyre,
Sweet flute, and *ten*-stringed instrument, require
Sounds of delight. *Prior.*

Although English is too little cultivated, yet the
faults are nine in *ten* owing to affectation.
Swift's Miscellanies.

TEN'ABLE, *adj.* Fr. *tenable*. Such as may
be maintained against opposition or attack.

The town was strong of itself, and wanted no in-
dustry to fortify and make it *tenable*.
Bacon's War with Spain.

Sir William Ogle seized upon the castle, and put
it into a *tenable* condition. *Clarendon.*

Infidelity has been driven out of all its out-works ;
the Atheist has not found his post *tenable*, and is
therefore retired into Deism. *Addison's Spectator*

TENA'CIOUS, *adj.* } Lat. *tenax*. Grasp-
TENA'CIOUSLY, *adv.* } ing hard ; inclined to
TENA'CIOUSNESS, *n. s.* } hold fast ; retentive ;
TENA'CITY. } cohesive ; not willing
to let go ; with *of* before the thing held : the ad-
verb and noun substantives corresponding.

Some things our juvenile reasons *tenaciously* adhere
to, which yet our maturer judgments disallow of.
Glanville.

Gripping, and still *tenacious* of thy hold,
Would'st thou the Grecian chiefs, though largely
souled,

Should give the prizes they had gained ? *Dryden.*
True love's a miser ; so *tenacious* grown,
He weighs to the least grain of what's his own. *Id.*

Men are *tenacious* of the opinions that first possess
them. *Locke.*

A resolute *tenacious* adherence to well chosen
principles, makes the face of a governor shine in the
eyes of those that see his actions. *South.*

Three equal round vessels filled, the one with
water, the other with oil, the third with molten pitch,
and the liquors stirred alike to give them a vertical
motion ; the pitch by its *tenacity* will lose its motion
quickly, the oil being less *tenacious* will keep it
longer, and the water being less *tenacious* will keep
it longest, but yet will lose it in a short time.
Newton.

If many contiguous vortices of molten pitch were
each of them as large as those which some suppose
to revolve about the sun and fixed stars, yet these
and all their parts would, by their *tenacity* and stiff-
ness, communicate their motion to one another till
they all rested among themselves. *Id.*

He is *tenacious* of his own property, and ready to
invade that of others. *Arbutnot.*

Substances, whose *tenacity* exceeds the powers of
digestion, will neither pass, nor be converted into ali-
ment. *Id.*

When winter soaks the fields, and female feet,
Too weak to struggle with *tenacious* clay,
Or ford the rivulets, are best at home,
The task of new discoveries falls on me. *Cowper.*

TENACITY, in natural philosophy, is that qua-
lity of bodies by which they sustain a consider-

able pressure or force of any kind without breaking. It is the quality opposite to fragility or brittleness. See **STRENGTH**.

TENACULUM, in surgery, an instrument used in amputation, for pulling out bleeding vessels that are to be tied by ligatures. See **SURGERY**, Index.

TENAILLES, and **TENAILLIONS**. See **FOR-TIFICATION**.

TENANCY, *n. s.* Old Fr. *tenanche*; law Lat. *tenentia*, from *tenant*. Temporary possession of what belongs to another.

This duke becomes seized of favour by descent, though the condition of that estate be commonly no more than a *tenancy at will*. *Wotton*.

TENANT, *n. s. & v. a.* } Fr. *tenant*. One
TEN'ANTABLE, *adj.* } that holds of an-
TEN'ANTLESS. } other; one that on
 certain conditions has temporary possession and use of that which is the property of another: correlative to *landlord*; the adjectives corresponding.

I have been your *tenant*,
 And your father's *tenant*, these fourscore years. *Shakespeare*.

O thou, that dost inhabit in my breast,
 Leave not the mansion so long *tenantless*;
 Lest growing ruinous the building fall,
 And leave no memory of what it was! *Id.*

The ruins that time, sickness, or melancholy, shall bring, must be made up at your cost; for that thing a husband is but *tenant* for life in what he holds, and is bound to leave the place *tenantable* to the next that shall take it. *Suckling*.

That the soul may not be too much incommoded in her house of clay, such necessities are secured to the body as may keep it in *tenantable* repair.

Decay of Piety.
 The English being only *tenants* at will of the natives for such convenience of fishing. *Heylyn*.

O fields, O woods, oh when shall I be made
 The happy *tenant* of your shade! *Cowley*.

Such is the mold, that the blest *tenant* feeds
 On precious fruits, and pays his rent in weeds. *Waller*.

Jupiter had a farm long for want of a *tenant*.
L' Estrange.

Sir Roger's estate is *tenanted* by persons who have served him or his ancestors. *Addison*.

His cheerful *tenants* bless their yearly toil,
 Yet to their lord owe more than to the soil. *Pope*.

The father is a tyrant over slaves and beggars,
 whom he calls his *tenants*. *Swift*.

The bear, rough *tenant* of these shades. *Thomson*.

The *tenants* of a manor fall into the sentiments of their lord. *Watts*.

The beams of April, ere it goes,
 A worm, scarce visible, disclose;
 All winter long content to dwell
 The *tenant* of his native shell. *Cowper*.

Kind souls! to teach their *tenantry* to prize
 What they themselves, without remorse, despise:

Nor hope have they, nor fear of aught to come,
 As well for them had prophecy been dumb. *Id.*

TENANT, in English law, is used with divers additions; thus, *tenant in dower*, is she that possesses land by virtue of her dower. *Tenant* by statute-merchant, he that holds land by virtue of a statute forfeited to him. *Tenant* in frank-marriage, he that holds lands or tenements by virtue of a gift thereof made to him upon marriage between him and his wife. *Tenant* by the curtesy,

he that holds for his life, by reason of a child begotten by him of his wife, being an inheritrix, and born alive. *Tenant* by elegit, that holds by virtue of the writ called an elegit. *Tenant* in mortgage, that holds by means of a mortgage. *Tenant* by the verge, in ancient demesne, who is admitted by the rod in the court of ancient demesne. *Tenant* by copy of court-roll, who is admitted *tenant* of any lands, &c., within a manor, which, time out of mind, had been demisable according to the custom of the manor. *Tenant* by charter, that holdeth by feoffment in writing, or other deed. There were also *tenants* by knights'-service, *tenant* in burgage, *tenant* in soccage, *tenant* in frank-fee, *tenant* in villeinage: so there is *tenant* in fee-simple; *tenant* in fee-tail; *tenant* at the will of the lord, according to the custom of the manor; *tenant* at will by the common law; *tenant* upon sufferance; *tenant* of estate of inheritance; *tenant* in chief, that holdeth of the king in right of his crown; *tenant* of the king's, he that holds of the person of the king, or has some honor; very *tenant*, that holds immediately of his lord, *Kitch. fol. 99*; *tenant* per-avail, the lowest *tenant* of the fee who is *tenant* to one who holds over of another. *F. N. B. 135*. So there are also joint-*tenants*, that have equal right in lands and tenements by virtue of one title; *tenants* in common, that have equal right, but hold by divers titles; particular *tenant*, as *tenant* for years, for life, &c., that holds only for his term; sole *tenant*, he that hath no other joined with him; several *tenant*, as opposite to joint-*tenant*, or *tenant* in common.

And there is *tenant* to the præcipe, in case of fines and recoveries; *tenant* in demesne, which is he that holdeth the demesnes of a manor for a rent, without service; *tenant* on service, he that holdeth by service; *tenants* by execution, that hold lands by virtue of an execution upon any statute, recognisance, &c., with divers others — *Cowell*.

TENANTS IN COMMON, are such as hold by several and distinct titles, but by unity of possession; because none knoweth his own severalty, and therefore they all occupy promiscuously. This tenancy therefore happens, where there is a unity of possession merely, but perhaps an entire disunion of interest, of title, and of time. For, if there be two *tenants* in common of lands, one may hold his part in fee-simple, the other in tail, or for life; so that there is no necessary unity of interest: one may hold by descent, the other by purchase; or the one by purchase from A., the other by purchase from B.; so that there is no unity of title. One's estate may have been vested fifty years, the other's but yesterday; so there is no unity of time. The only unity there is, is that of possession: and for this Littleton gives the true reason, because no man can certainly tell which part is his own. otherwise, even this would be soon destroyed.—2 *Comm. c. 12*.

Tenancy in common may be created, either by the destruction of two estates, in joint-tenancy and co-parcenary, or by special limitation in a deed. By the destruction of the two estates mentioned is intended such destruction as does not sever the unity of possession, but only the

unity of title or interest. as, if one of two joint-tenants in fee alienates his estate for the life of the alienee, the alienee and the other joint-tenant are tenants in common; for they now have several titles, the other joint-tenant by the original grant, the alienee by the new alienation; and they also have several interests, the former joint-tenant in fee-simple, the alienee for his own life only. Litt. s. 293. So, if one joint-tenant gives his part to A. in tail, and the other gives his to B. in tail, the donees are tenants in common, as holding by different titles and conveyances. Litt. s. 292. If one or two parceners alienates, the alienee and the remaining parcener are tenants in common; because they hold by different titles, the parcener by descent, the alienee by purchase. Litt. s. 309. So likewise, if there be a grant to two men, or two women, and the heirs of their bodies, here the grantees shall be joint-tenants of the life-estate, but they shall have several inheritances; because they cannot possibly have one heir of their two bodies, as might have been the case had the limitation been to a man and a woman, and the heirs of their bodies begotten: and, in this and the like cases, their issues shall be tenants in common; because they must claim by different titles, one as heir of A., and the other as heir of B.; and those too not titles by purchase, but descent. See Litt. s. 283. In short, whenever an estate in joint-tenancy or coparcenary is dissolved, so that there be no partition made, but the unity of possession continues, it is turned into a tenancy in common. 2 Comm. c. 12. A tenancy in common may also be created by express limitation in a deed: but here care must be taken not to insert words which imply a joint estate; and then if lands be given to two or more, and it be not joint-tenancy, it must be a tenancy in common. Land given to two, to be holden, the one moiety to one, and the other moiety to the other, is an estate in common; and, if one grants to another half his land, the grantor and grantee are also tenants in common: because joint-tenants do not take by distinct halves or moieties; and by such grants the division and severalty of the estate is so plainly expressed that it is impossible they should take a joint interest in the whole of the tenements. But a devise to two persons to hold jointly and severally has been held to be a joint-tenancy; because that is necessarily implied in the word 'jointly;' the word 'severally,' perhaps only implying the power of partition: and an estate given to A. and B., equally to be divided between them, though in deeds it hath been said to be a joint-tenancy (for it implies no more than the law has annexed to that estate, viz. divisibility), yet in wills it is certainly a tenancy in common, because the deviser may be presumed to have meant what is most beneficial to both the devisees, though his meaning is imperfectly expressed. See 1 Eq. Ab. 291: 1 P. Wms. 17: 3 Rep. 39: 1 Vent. 32. And this nicety in the wording of grants makes it the most usual as well as the safest way (in them as well as in wills), when a tenancy in common is meant to be created, to add express words of exclusion as well as description, and limit the estate to A and B., to hold as tenants in common and not as joint-tenants.

The tenure of joint-tenants, though formerly favored in law, is now considered as odious. In consequence of this, in wills, the expressions, equally to be divided, share and share alike, respectively between and amongst, have been held to create a tenancy in common. And there seems but little doubt that the same construction would now be put even upon the word severally; but these words certainly are only evidence of intention, and will not create a tenancy in common, where the contrary, from the other parts of the will, appears to be the manifest intention of the testator.—3 Bro. C. R. 215.

As to the incidents attending a tenancy in common: tenants in common (like joint-tenants) are compellable by the statutes 31 Hen. VIII. c. 1; 32 Hen. VIII. c. 32, to make partition of their lands; which they were not at common law. They properly take by distinct moieties, and have no entirety of interest; and therefore there is no survivorship between tenants in common. Their other incidents are such as merely arise from the unity of possession; and are therefore the same as appertain to joint-tenants merely upon that account: such as being liable to reciprocal actions of waste and of account, by the stats. Westm. 2. c. 22: 4 Ann. c. 16, and see 8 Term Rep. K. B. 145.—For by the common law no tenant in common was liable to account with his companion for embezzling the profits of the estate; though, if one actually turns the other out of possession, an action of ejectment will lie against him.—1 Inst. 199, 200. See 2 Comm. c. 12. Adverse possession, or the uninterrupted receipt of the rents and profits, is now held to be evidence of an actual ouster. And where one tenant in common has been in undisturbed possession for twenty years, in an ejectment brought against him by the co-tenant, the jury will be directed to presume an actual ouster, and consequently to find a verdict for the defendant.—Cowp. 217. Other incidents of joint-tenants, which arise from the privity of title, or the union and entirety of interest (such as joining or being joined in actions, unless in the case where some entire or indivisible thing is to be recovered), these are not applicable to tenants in common, whose interests are distinct, and whose titles are not joint, but several.

Estates in common can only be dissolved two ways. 1. By uniting all the titles and interests in one tenant, by purchase or otherwise; which brings the whole to one severalty. 2. By making partition between the several tenants in common, which gives them all respective severalties. For indeed tenancies in common differ in nothing from sole estates, but merely in the blending and unity of possession.

TENANT-SAW seems rather to be derived from tenant, and it is a principal instrument used in that branch of carpentry.

TENAR, or THENAR, in anatomy, the muscle, which draws the thumb from the fingers, called also abductor brevis pollicis, and abductor pollicis manus. See ABDUCTOR, and ANATOMY.

TENASSERIM, or TANENGARI, a district in the Birman empire, extending along the sea coast from 11° to 14° N. lat. The west coast is protected from the south-west monsoon, by a

connected barrier of islands, extending 135 miles from north to south, with a strait between them and the main land, from fifteen to thirty miles broad. The language of the inhabitants, denominated Tinnaw by the Siamese, differs considerably from the common Birman, and has many peculiarities. The natives are named by the Birman Dawayza and Byeitza, from the two governments of which their country consists. They have most frequently been subject to Siam and Pegu.

TENASSERIM, a post town in the Birman empire, the capital of a province of the same name. Lat. 11° 42' N., long. 96° 50' E. In 1688 the court of directors of the East India Company ordered their servants at Madras to endeavour to obtain possession of it from the king of Siam, and to fortify it. In 1759 it was taken from the Siamese by Alompra, the Birman monarch, after a feeble resistance. It was then a flourishing place.

TENBURY, a market town of Doddingtree hundred, Worcestershire, situate on the river Teme, which divides it from Salop. Nine miles north-east from Leominster, and 134 north-west from London. The town is well built and partly paved. Over the Teme is a neat stone bridge of six arches. The church has a square tower, with six bells. The corn-market is an ancient building; but the butter-cross modern and convenient. The trade of the town is principally in hops, cyder, and the tanning of leather. The Leominster canal runs at a short distance. Market on Tuesday. Fairs, April 25th, July 18th, and September 26th. Here are annual horse-races.

TENBY, or TENBIGH, a sea-port town of South Wales in Pembrokeshire, with markets on Wednesdays and Saturdays. It is a rapidly improving and beautiful bathing place, and is remarkable for the exquisitely romantic and picturesque charms of its situation, being on the western edge of the fine bay of Caermarthen, with a harbour capable of sheltering vessels of 200 or 300 tons burden. The Tenby season usually commences in May and ends in October. It is ten miles east of Pembroke, and 250 west of London, and shares with Pembroke and other places in sending a member to parliament.

TENCH, *n. s.* Sax. *tinca*; Lat. *tinca*. A pond fish.

Having stored a very great pond with carps, *tench*, and other pond-fish, and only put in two small pikes, this pair of tyrants in seven years devoured the whole. *Hale.*

TENCH, in ichthyology. See *CYPRINUS*.

TENCHTHERI, an ancient nation of Germany, who often changed the place of their residence. Tacitus, Ann. xiii. c. 56, II. iv. c. 21.

TEND, *v. a. & v. n.* Contracted from *TENDANCE, n. s.* } tend. To accompany
TENDENCE, } as an assistant or de-
TENDENCY, } fender; watch; guard:

as a verb neuter, move toward a given point; to aim at; contribute; wait; attend: tendance is, state of or persons attending; care; act of tending: tendence and tendency, direction; course; drift.

Unhappy wight, born to disastrous end,
 That doth his life in so long *tendancē* spend! *Spenser.*

Nymphs of Mulla which, with careful heed,
 The silver scaly trouts did *tend* full well.

Go thou to Richard, and good angels *tend* thee!
Id. Epithal.
Shakspeare.

She purposed,
 By watching, weeping, *tendance*, to
 Overcome you with her shew. *Id. Cymbeline.*

The bark is ready, and the wind at help;
 The associates *tend*. *Id. Hamlet.*

His lobbies fill with *tendance*,
 Rain sacrificial whisperings in his ear! *Shakspeare.*

Give him *tending*,
 He brings great news. *Id.*

They had a view of the princess at a mask, having
 Overheard two gentlemen *tending* towards that sight.
Wotton.

Many times that which we ask would, if it should
 be granted, be worse for us, and perhaps *tend* to our
 destruction; and then God, by denying the particu-
 lar matter of our prayers, doth grant the general
 matter of them. *Hammond.*

It is not much business that distracts any man,
 but the want of purity, constancy, and *tendency* to-
 wards God. *Taylor.*

The greater congruity or incongruity there is in
 any thing to the reason of mankind, and the
 greater *tendency* it hath to promote or hinder the
 perfection of man's nature, so much greater degrees
 hath it of moral good or evil; to which we ought to
 proportion our inclination or aversion. *Wilkins.*

Despair
Tended the sick, busiest from couch to couch.
Milton.

Admiration seized
 All heaven, what this might mean and whither *tend*.
Id.

They at her coming sprung,
 And touched by her fair *tendance* gladlier grew. *Id.*
 The laws of our religion *tend* to the universal hap-
 piness of mankind. *Tillotson.*

He led a rural life, and had command
 O'er all the shepherds, who about those vales
Tended their numerous flocks.

Dryden and Lee's Oedipus.
 To these abodes our fleet Apollo sends:
 Here Dardanus was born, and hither *tends*.

Dryden.
 These opinions are of so little moment that, like
 motes in the sun, their *tendencies* are little noticed.
Locke.

Writings of this kind, if conducted with candour,
 have a more particular *tendency* to the good of their
 country, than any other compositions.
Addison's Freeholder.

All of them are innocent, and most of them had
 a moral *tendency* to soften the virulence of parties,
 or laugh out of countenance some vice or folly.
Swift.

Those with whom I now converse
 Without a tear will *tend* my horse. *Id.*

Our humbler province is to *tend* the fair;
 To save the powder from too rude a gale,
 Nor let the imprisoned essences exhale. *Pope.*

We may acquaint ourselves with the powers and
 properties, the *tendencies* and inclinations, of body
 and spirit. *Watts.*

TEND'ER, *adj., v. a., & n. s.* } Fr. *tendre.*
 TEND'ERLY, *adv.* } Soft; easily

TEND'ERNESS, *n. s.* } impressed or
 injured; sensible; dilute; not firm or hard: amor-
 ous; young; weak: as a verb active, to offer;
 exhibit; hold; esteem; hold in regard or kind-
 ness: an offer; proposal; regard; concern: the

adverb and noun substantive following agree with tender, adjective.

Instead of their warlike music [Cyrus] appointed to them certain lascivious lays, by which their minds were so mollified and abated, that they forgot their former fierceness, and became most tender and effeminate. *Spenser on Ireland.*

The tender kindness of the church it well beseebeth to help the weaker sort, although some fell of the perfecter and stronger be for a time displeas'd.

Some of the chiefest laity professed with greater stomach their judgments, that such a discipline was little better than popish tyranny disguised, and tendered unto them. *Hooker.*

Think yourself a baby;
That you have ta'en his tenders for true pay,
Which are not sterling. *Shakspeare. Hamlet.*

I thank you, madam, that you tender her:
Poor gentlewoman, my master wrongs her much. *Shakspeare.*

Unneath may she endure the flinty street,
To tread them with her tender feeling feet! *Id.*

Tenderly apply to her
Some remedies for life. *Id.*

I love Valentine;
His life's as tender to me as my soul. *Id.*

Well we know your tenderness of heart,
And gentle, kind, effeminate remorse
To your kindred. *Id. Richard III.*

All conditions, all minds, tender down
Their service to lord Timon. *Shakspeare.*

Tender yourself more dearly;
Or, not to crack the wind of the poor phrase,
Wringing it thus, you'll tender me a fool. *Id.*

Some are unworthily censured for keeping their own, whom tenderness how to get honestly teacheth to spend discreetly; whereas such need no great thriftiness in preserving their own, who assume more liberty in exacting from others. *Wotton.*

In things that are tender and unpleasing, break the ice by some whose words are of less weight, and reserve the more weighty voice to come in as by chance. *Bacon.*

Pied cattle are spotted in their tongues, the tenderness of the part receiving more easily alterations than any other parts of the flesh. *Id.*

Beneath the dens where unfetched tempest lie,
And infant winds their tender voices try. *Cowley.*

From each tender stalk she gathers.
This not mistrust but tender love enjoins. *Milton.*

Owe not all creatures by just right to thee
Duty and service, not to stay till bid,
But tender all their power? *Id. Paradise Regained.*

She embraced him, and for joy
Tenderly wept. *Milton.*

What mad lover ever died,
To gain a soft and gentle bride?
Or, for a lady tender-hearted,

In purling streams or hemp departed? *Hudibras.*

The civil authority should be tender of the honour of God and religion. *Tillotson.*

Be tender-hearted and compassionate towards those in want, and ready to relieve them. *Id.*

The earl accepted the tenders of my service. *Dryden.*

Our bodies are not naturally more tender than our faces; but, by being less exposed to the air, they become less able to endure it. *L'Estrange.*

The face when we are born is no less tender than any other part of the body: it is use alone hardens it, and makes it more able to endure the cold. *Locke on Education.*

A quickness and tenderness of sight could not endure bright sunshine. *Locke.*

True tenderness of conscience is nothing else but an awful and exact sense of the rule which should direct it; and, while it steers by this compass, and is sensible of every declination from it, so long it is properly tender. *South.*

To declare the calling of the Gentiles by a free unlimited tender of the gospel to all. *Id. Sermons.*

As I have been tender of every particular person's reputation, so I have taken care not to give offence. *Addison.*

With what a graceful tenderness he loves!
And breathes the softest, the sincerest vows! *Id.*

Our tenders of duty every now and then miscarry. *Id.*

There being implanted in every man's nature a great tenderness of reputation, to be careless of it is looked on as a mark of a degenerate mind. *Government of the Tongue.*

He had never heard of Christ before; and so more could not be expected of him than to embrace him as soon as he was tendered to him. *Duty of Man.*

When the frame of the lungs is not so well woven, but is lax and tender, there is great danger that, at or spitting of blood, they will by degrees putrify and consume. *Blackmore.*

The difference of the muscular flesh depends upon the hardness, tenderness, moisture or dryness of the fibres. *Arbutnot.*

There are examples of wounded persons, that have roared for anguish at the discharge of ordnance, though at a great distance; what insupportable torture then should we be under upon a like concussion in the air, when all the whole body would have the tenderness of a wound! *Bentley's Sermons.*

Marcus with blushes owns he loves,
And Brutus tenderly reproves. *Pope.*

As in the bosom of the stream
The moon-beam dwells at dewy c'en;
So trembling, pure, was tender love,

Within the breast o' bonnie Jean. *Burns.*

They are the most perfect pieces of Ovid, and the style tenderly passionate and courtly. *Preface to Ovid.*

TENDER, in law, is the offering of money or any other thing in satisfaction; or circumspectly to endeavour the performance of a thing; as a tender of rent is to offer it at the time and place when and where it ought to be paid. See RENT. Also it is an act done to save the penalty of a bond before action brought, &c. There are several statutes which authorise a tender of amends where otherwise it would not have been allowable. As stat. 11 Geo. II. c. 19, § 20, in cases of distress for rent. Stat. 17 Geo. II. c. 38, § 10, in cases of distress for poor's rates. Stat. 24 Geo. II. c. 44, in actions against justices of the peace. Stat. 23 Geo. III. c. 70, § 30, in actions against excise officers. And stat. 24 Geo. III. c. 47, § 35, in actions against custom-house officers.

Tender of money on a bond is to be made to the person of the obligee at the day appointed to save the penalty and forfeiture of the bond, and it ought to be done before witnesses; though, if the obligor be sued afterwards, he must still pay it. But if the obligor be to do any collateral thing, or which is not part of the obligation, as to deliver a horse, &c., and the obligor offer to do his part, and the obligee refuseth it, the condition is performed, and the obligation discharged for ever. By stat. 4 & 5 Ann. c. 16, § 12, the plea of solvit post diem is granted to an ob-

tion on bond; but a tender and refusal of principal and interest at a subsequent day cannot be pleaded, as not being within the equity of the statute: for such construction would be prejudicial; as it would empower the obligor, at any time, to compel the obligee to take his money without notice.—Bull. Ni. Pri. 171: Sellon's Pract. Tender.

Every tender at the common law, or which is given by statute, must be made before the writ sued out. If a tender be in fact made before the bringing of the action, though, by the teste of the writ it may appear to have been afterwards (as if tender in vacation and teste of preceding term), the exact time when the writ was in fact sued out may be shown in pleading, or sometimes given in evidence contrary to the teste: but if a bill be filed on the same day the tender is made, though subsequent thereto, it seems that the defendant can no way avail himself by pleading the prior tender; as there is no fraction of a day in law.—See Sellon's Pract. Tender.

It is no answer to a plea of tender, before the exhibiting of the plaintiff's bill, that the plaintiff had before such tender retained an attorney, and instructed him to sue out a writ against the defendant; and that the attorney had accordingly applied, before the tender, for such writ, which was afterwards sued out. A right to damages on account of the non-payment of a debt, or non-performance of a duty, may, after being taken away by a tender and refusal, be revived again by a demand subsequent to the tender and refusal; a new cause of action arises from the non-payment or non-performance thereof upon such demand: and therefore the plaintiff may reply such subsequent demand and refusal by the defendant, which, if proved, the plaintiff must have a verdict.—Brownl. 7.

Wherever the debt or duty arises at the time of the contract, and is not discharged by a tender and refusal, it is not enough for the party who pleads the tender, to plead a tender and refusal, and uncore prist (that he is still ready), but he must also plead tout temps prist (that he was always ready).

A plea of tender after the day of payment of a bill of exchange, and before action brought, is not good; though the defendant aver that he was always ready to pay from the time of the tender, and that the sum tendered was the whole money then due, owing, or payable to the plaintiff in respect of the bill, with interest from the time of the default, for the damages sustained by the plaintiff, by reason of the non-performance of the promise.—8 East's Rep. 168. Every requisite which is in a particular case necessary to the validity of a tender must, in pleading such tender, be showed to have been complied with; else the plea is not good.—Salk. 624.

On a tender being pleaded, and the money paid into court, the plaintiff replied a subsequent demand and refusal, whereupon issue being joined and tried, a verdict was found for the defendant. Whereupon he moved to have the money paid into court returned, in part of his costs; but the court was of opinion it could not be done.—Hardw. 206. Though a tender is made, and the plaintiff refuses the money, yet

the tender cannot be pleaded in bar of the action either in debt or assumpsit, but in bar of the damages only.—Ld. Raym. 254.

There is a difference in pleading a tender in action of debt, and in action on the case: in an action of debt, the defendant ought to conclude his plea by praying judgment, if the plaintiff ought to have or maintain his action to recover any damages against him; for, in this action, the debt is the principal, and the damages are only accessory. But, in assumpsit, the damages are the principal; and therefore, in pleading a tender, the defendant ought to conclude his plea with a prayer of judgment, if the plaintiff ought to have or maintain his action, to recover any more or greater damages than the sum tendered, or any damages by reason of the non-payment thereof.

Tender may be of money in bags, without showing or telling it, if it can be proved there was the sum to be tendered; it being the duty of him that is to receive the money to put out and tell it.—5 Rep. 115. Though where the person held the money on his arm in a bag, at the time of offering, this was adjudged no good tender, for it might be counters or base money.—Noy. 74. A tender in bank notes is sufficient, unless the creditor expressly refuses to receive notes, and insists upon cash. If a tender is made of more than is due it is good.

TENDO ACHILLIS, in anatomy, the tendon of Achilles, a large tendon of the heel, so named from the tradition that Achilles got his mortal wound in that part. See ANATOMY. The celebrated Dr. Monro senior made a capital cure of a rupture of this tendon upon himself. See SURGERY.

TEN'DON, *n. s.* } Lat. *tendon*. A sinew;
TEN'DINOUS, *adj.* } a ligature by which the joints are moved: the adjective corresponding.

The entrails these embrace in spiral strings. Those clasp the arterial tubes in tender rings; The tendons some compacted close produce, And some thin fibres for the skin diffuse.

Blackmore.

Nervous and *tendinous* parts have worse symptoms, and are harder of cure than fleshy ones. *Wiseman.*

A struma in her instep lay very hard and big amongst the tendons. *Id. Surgery.*

TENDONS, in anatomy, are white, firm, and tenacious parts, contiguous to the muscles, and usually forming their extremities. See ANATOMY.

TEN'DRIL, *n. s.* Fr. *tendrillon*. The clasp of a vine or other climbing plant.

In wanton ringlets waved,
As the vine curls her tendrils; which implied
Subjection. *Milton's Paradise Lost.*

So may thy tender blossoms fear no blite;
Nor goats with venom'd teeth thy tendrils bite.

Dryden.

The tendrils or clasps of plants are given only to such as have weak stalks, and cannot raise up or support themselves. *Ray on the Creation.*

TENEBRIO, in entomology, a genus of insects belonging to the order of coleoptera. The antennæ are moniliform, the last joint being roundish; the thorax is plano-convex and marginated; the head projecting, and the elytra are somewhat stiff. Gmelin enumerates about sixty-three species: The larvæ of some live in damp

places under ground among rubbish; of others in flour and different kinds of food, where they undergo their metamorphosis. The perfect insects are very troublesome in houses, eating bread, meat, &c. They precipitately avoid the light; resorting in troops to dark damp cellars, where putrefaction allures and nourishes them. They are all of a very dark gloomy appearance, from which circumstance they take their name.

TENEDIA SECURIS [Lat.], i. e. the axe of Tenedos, a proverbial expression for a severe law, derived from a law made by Tenes the first king of that island, that adulterers should be beheaded with an axe. See **TENEDOS**. This sentence was executed on the king's son. Aristotle says that this was commemorated on the coins of Tenedos, which on one side had two heads of the king and his son, and on the reverse an axe.

TENEDOS, in ancient geography, an island on the coast of Troas, forty stadia from the continent, and eighty in compass; with a cognominal Æolian town, and a temple of Apollo Smintheus. Its origin is derived from Tenes, who being exposed in a coffer or bog by his father Cygnus the Thracian, at the instigation of his stepmother, was by fate carried to this island, made king of it, and at length worshipped as a god on account of his virtues. The island was famous for its earthen-ware, for which purpose it had an excellent red clay; and hence Bochart would derive the appellation from *tinedom*, a red clay. This island still retains its ancient name, and is one of the smallest of the archipelago, situated near the coast of Lesser Asia, west of the ruins of Troy.

TENEDOS, a small rocky island of the Grecian archipelago, close to the coast of Asia Minor and at a small distance from the entrance of the Dardanelles. It is mentioned by Homer under the name which it now bears, and its position tends to identify the site of the plain of Troy. Vessels bound to the city successively called Byzantium and Constantinople have found shelter in its ports, or safe anchorage in the road, during contrary winds. The emperor Justinian erected a large magazine here. In 1302 it was annexed by the caliph Othman to the Turkish empire. The harbour has formerly been enclosed by a mole, of which no part now appears above water, but loose stones are piled on the foundations. The Turks give to it now the name of *Bogteha-Adassi*. This island is remarkable for producing the finest wine in the archipelago. A mountainous ridge encloses the port, and the town stands on the slope of a hill. It is supposed to contain 600 Turkish and 300 Greek families. Long. 26° E., lat. 39° 53' N.

TENEMENT, *n. s.* Fr. *tenement*; law Lat. *tenementum*. Any thing held by a tenant.

What reasonable man will not think that the *tenement* shall be made much better, if the tenant may be drawn to build himself some handsome habitation thereon, to ditch and enclose his ground.

Spenser on Ireland.

'Tis policy for father and son to take different sides; for then lands and *tenements* commit no treason.

Dryden.

Who has informed us that a rational soul can inhabit no *tenement*, unless it has just such a sort of frontispiece.

Locke.

Treat on, treat on, is her eternal note,
And lands and *tenements* glide down her throat.

Pope.

TENERIFFE, a considerable island of the group of the Canaries, off the western coast of Africa. It is of a triangular form, each side being about thirty-six miles in length. It is chiefly remarkable for its lofty peak, of the sloping sides of which the island actually consists, and the volcanic eruptions which issue from its sides. By none, however, has it been so carefully examined as by Humboldt.

The climate is delightful and salutary; and by the rapidity of its rise it presents, within a very short distance, every variation of temperature, from the colder climates of Europe to those of the equinoctial regions. The port of Santa Cruz, indeed, from which the principal trade is carried on, is intensely hot, not only from the lowness of its situation, but from the reflection of the basaltic rocks above it. Laguna, however, elevated about 2000 feet above it, is cool and agreeable. Nothing prevents it from being the capital of the island, except the filling up of its port of Garachico by the ravages of a volcano. Teneriffe is here encircled by a darkish brown basaltic rock, which, however, is not formed into columns. The traveller, crossing a hilly tract from Laguna, comes to the western coast, of the beauty of which all visitors speak with enthusiasm.

Humboldt, after having traversed the banks of the Orinoco, the Cordilleras, and the most beautiful valleys of Mexico, declares that he never beheld a landscape more agreeable, more harmonious, and more attractive. Orange, myrtle, and cypress trees, entwine the chapels reared on the eminences. The declivities and rising hills are covered with vines and cultivated like a garden. Perpetual spring prevails in the district, and in the summer evenings the breeze from the sea comes loaded with delicious coolness. In this part of the island the date tree, the plantain, the sugar-cane, the Indian fig, the arum colocasia (the root of which furnishes the lower class with a nutritive meal), the olive tree, the fruit trees of Europe, the vine and corn, are cultivated. Wheat is reaped from the end of March to the beginning of May; and the culture of the bread-fruit tree of Otaheite, of the cinnamon, the coffee, and the cocoa, have been tried with success. Above this fertile tract rises what is called the region of the laurels, forming an extensive border that extends all round Teneriffe. These trees are fed by a vast number of springs that rise up amid a turf covered with perpetual verdure. Extensive plantations of chestnut occur in the lower part, above which rise four species of laurel, and an oak resembling that of Thibet, besides some other trees. The underwood in the lower part consists of arborescent heath, and in the upper part of ferns. Above this is a vast forest of oak and pine, those trees which characterise the colder regions of the earth. The prevailing species has the appearance of the Scotch fir, with very long and stiff leaves sprouting by two, or oftener by three in one sheath. Above this is a vast plain, like a sea of sand, covered with the dust of pumice stone, which continually fills the air. It is embellished with tufts of the

beautiful shrub called the retama, growing to the height of nine feet, and loaded with odoriferous flowers. It is said to communicate a peculiar excellence to the flesh of the goats which feed upon it. At the entrance of this plain the rich verdure of the island terminates, as well as all appearance of habitation; and the traveller ascends afterwards through a complete solitude. Above this plain are the Malpays, a name which the Spaniards, in all their volcanic districts, apply to a ground destitute of vegetable mould, and covered with loose and broken fragments of lava. The ascent here is steep and extremely fatiguing, as the blocks of lava roll from beneath the feet and often leave deep hollows. At the extremity of the Malpays are found those spiracles which are called by the natives the Nostrils of the Peak, consisting of watery and heated vapors, which issue at intervals from crevices in the ground. The Piton, or summit, is of a conical form; the ascent steep, and rendered difficult by the loose ashes with which it is covered. At the top there is scarcely room to stand, and the crater is enclosed by a wall so steep that it could not be entered were there not a breach in one spot. The sides of the crater are almost perpendicular, though it can be descended by pieces of broken lava. This crater has long ceased to emit flames, and the heat is perceptible only in a few crevices which give vent with a buzzing noise to aqueous vapors. The view from the top is characterised by peculiar beauty.

From the flanks of the Peak several violent eruptions have taken place in the course of the present century. In 1704 there occurred one in the district of Guimar, which buried several valleys, and approached within a short distance of the port of Orotava. Two years after, the lava issuing forth in a different quarter, buried the port of Garachico, then the finest and most frequented harbour in the island. In two hours this opulent and populous city was totally destroyed, not a single edifice being left standing. The port was filled up and converted into a promontory, and the whole surface of the surrounding country entirely changed. The volcanic power now remained dormant for nearly a century, till 1796, when the mountain of Chahorra, which had always been considered as an extinguished volcano, began pouring out, by four mouths, vast torrents of lava for three months and six days, but being fortunately in an uncultivated part of the island no serious injury followed. The commercial importance of Teneriffe depends chiefly on its wine, which is in considerable demand. From 10,000 to 15,000 pipes are annually exported.

TENES, the first king of Tenedos, who acquired his kingdom in consequence of his step-mother Philonome's lust, and his father's credulity. See TENEDIA and TENEDOS.

TENESIS, a district of ancient Ethiopia. Strabo.

TENESMUS, *n. s.* Barb. Lat. *tenesmus*. Defined below.

The stone shutting up the orifice of the bladder is attended with a *tenesmus*, or needing to go to stool.

Arbutnot.

TENESMUS, in medicine, a name given by

medical writers to a complaint which is a continual desire of going to stool, but without any stool being ready to be voided. This is properly no primary disease, but merely a symptomatic one, and differs in degree according to the disease on which it is an attendant. See MEDICINE.

TEN'ET, *n. s.* Lat. *tenet*, he holds. Sometimes written tenent. Position; principle; opinion.

While in church matters, profit shall be the touchstone for faith and manners, we are not to wonder if no gainful *tenet* be deposited. *Decay of Piety.*

That all animals of the land are in their kind in the sea, although received as a principle, is a *tenet* very questionable. *Broune's Vulgar Errors.*

This savours of something ranker than Socinianism, even the *tenets* of the fifth monarchy, and of sovereignty founded only upon saintship. *South.*

They wonder men should have mistook
The *tenets* of their master's book.

Prior.

TENIERS (David), the elder, a Flemish painter, born at Antwerp in 1582. He received the first rudiments of his art from the famous Rubens, and afterwards finished his studies at Rome. He attached himself to Adam Elsheimer for six years; and formed to himself a peculiar style, which his son cultivated so happily afterwards as to bring it to the utmost perfection. His pictures were small; and his subjects usually shops, laboratories, humorous conversations, and rural festivities. He died at Antwerp in 1649.

TENIERS (Abraham), son of David, was equal to his father and brother in the expression of his characters, and in the clara obscuro; though he was inferior in sprightliness of touch and lightness of pencil.

TENIERS (David), the younger, also an admirable painter, was the son of the former, and was born at Antwerp in 1610. He obtained the name of Ape of Painting, from his imitating the manner of different painters with such exactness as to deceive even the nicest judges. His principal talent lay in landscapes adorned with small figures. He also painted men drinking and smoking, chemists' laboratories, country fairs, and the like. His small figures are superior to his large ones. He died in 1694.

TENISON (Dr. Thomas), archbishop of Canterbury, was born at Cottenham in Cambridgeshire in 1636; and studied at Corpus Christi College in Cambridge. In his youth he applied himself to physic; but afterward went into orders, and became minister of St. Andrew's church, Cambridge. He showed himself very active against the growth of popery, by his writings, both in the reigns of Charles II. and James II. In 1680 he was made vicar of St. Martin's in the Fields, London, to which parish he made several donations; and, among others, endowed a free school and built a handsome library, which he furnished with useful books. King William and queen Mary, in 1689, appointed him archdeacon of London; in 1691 he was nominated bishop of Lincoln; and in 1694 he succeeded Dr. Tillotson as archbishop of Canterbury. He performed all the duties of a good primate for twenty years, and died in 1715.

TENNESSEE, one of the United States of North America, bounded north by Kentucky; east by North Carolina and Virginia; south by Georgia, Alabama territory, and Mississippi state; and west by the Mississippi. Long. 81° 28' to 91° 37' W. It is 420 miles long and 102 broad; containing 40,000 square miles. The number of militia in 1812 was 29,193. This state is divided by the Cumberland mountains into two divisions, East Tennessee and West Tennessee. The counties, population in 1810, and chief towns, are exhibited in the following table:—

EAST TENNESSEE.

Counties.	Pop.	Chief Towns.
Anderson . . .	3,959	Clinton
Bledsoe . . .	8,839	Pikeville
Blount . . .	3,259	Maryville
Campbell . . .	2,668	Jacksonburg
Carter . . .	4,190	Elizabethtown
Claiborne . . .	4,798	Tazewell
Cocke . . .	5,154	Newport
Cranger . . .	6,397	Rutledge
Greene . . .	9,713	Greenville
Hawkins . . .	7,643	Rogersville
Jefferson . . .	7,309	Dandridge
Knox . . .	10,171	Knoxville
Rhea . . .	2,504	Washington
Roane . . .	5,581	Kingston
Sevier . . .	4,595	Sevierville
Sullivan . . .	6,847	Blountsville
Washington . . .	7,740	Jonesborough

WEST TENNESSEE.

Counties.	Pop.	Chief Towns.
Bedford . . .	8,247	Shelbyville
Davidson . . .	15,608	Nashville
Dickson . . .	4,516	Charlotte
Franklin . . .	5,730	Winchester
Giles . . .	4,536	Pulaski
Hickman . . .	2,583	Vernon
Humphries . . .	1,511	Reynoldsburg

branch at Nashville. There are independent banks at Nashville and Franklin. These three banks have each a capital of 400,000 dollars. The legislature, in 1817, granted charters for ten new banks, with a capital of 400,000 dollars each, to be established at Murfreesborough, Jonesborough, Columbia, Maryville, Shelbyville, Rogersville, Fayetteville, Carthage, Nashville, and Kingston. Four colleges have been incorporated in this state at Knoxville, Nashville, Greenville, and in Washington county. Those at Knoxville and Nashville have never gone into operation. There are academies at Knoxville, Nashville, Carthage, Murfreesborough, Rogersville, Gallatin, Fayetteville, and near Franklin, Springfield, Lebanon, and Clarkesville. The principal denominations of Christians in Tennessee are Baptists, Methodists, and Presbyterians. The legislature is composed of a senate and house of representatives; the members of each, together with the governor, are chosen biennially on the first Thursday in August and the day succeeding. The meeting of the general assembly is on the third Monday in September.

Tennessee is marked by bold features. It is washed by the great river Mississippi on the west, and the fine rivers Tennessee and Cumberland pass through it in very serpentine courses. The western part is undulating; some of it level; in the middle it is hilly; and the eastern part, known by the name of East Tennessee, abounds in mountains, many of them lofty, and presenting scenery peculiarly grand and picturesque. Of these mountains the Cumberland, or great Laurel Ridge, is the most remarkable. Stone, Yellow, Iron Bald, Smoky, and Unaka mountains, join each other, and form, in a direction nearly north-east and south-west, the eastern boundary of the state. North-west of these, and separated from each other by valleys of from five to fifteen miles wide, are Bay's Mountain, Copper Ridge, Clinch Mountain, Powell's Mountain, and Welling's Ridge. The last four terminate north of Tennessee river. The principal rivers are the Tennessee, Cumberland, Holston, Clinch, French-Broad, Nolachucky, Hiwassee, Tellico, Duck, Reelfoot, Obian, Forked Deer, and Wolf. The mountains last mentioned are all encircled by valleys which open passages for rivers and roads, and which, together with the numerous cascades, render the views very sublime. Caves of great depth and extent are found throughout the state.

The geological formation of this state is wholly secondary, except a small portion of the eastern part which is transition, and numerous spots on the banks of rivers which are alluvial. A considerable portion of the state is bedded on limestone. A large deposit of gypsum has been lately discovered. Copperas, alum, nitre, and lead, are among the minerals. Some silver has been found. Coal is supposed to be plentiful. Saltpetre is so abundant as to form a great article of commerce. There are several mineral springs, and many valuable salt springs. The soil in a country so uneven must be very various. The western part of the state has a black rich soil; in the middle are great quantities of excellent land; in the eastern part of the mountains are lean, but many fertile valleys.

Murfreesborough is the seat of government. The other most considerable towns in West Tennessee are Nashville, Franklin, Fayetteville, Shelbyville, Columbia, Clarkesville, Carthage, and Gallatin; in East Tennessee, Knoxville, Jonesborough, Greenville, and Rogersville. The state bank of Tennessee is at Knoxville, with a

There is a great profusion of natural timber, poplar, hickory, walnut, oak, beach, sycamore, locust, cherry, sugar-maple, &c., and in many places are great quantities of cane remarkably thick and strong. The state also abounds with medicinal plants, such as snake root, ginseng, Carolina pink, angelica, senna, annise, spikenard, &c. Tennessee is also well supplied with animals and birds of various kinds, and the rivers abound in divers sorts of fish.

The climate is generally healthy. In East Tennessee the air is so tempered by the mountain air on one side, and by refreshing breezes from the gulf of Mexico on the other, that this part of the state has one of the most desirable climates in North America. The middle part resembles Kentucky in climate. The winter in Tennessee resembles the spring in New England. Snow seldom falls to a greater depth than ten inches, or lies longer than ten days. Cumberland river has been frozen over but three times since the country was settled. Cattle are rarely sheltered in winter. In the western parts there are some low bottoms on which the inhabitants are subject to bilious fevers; and fever and ague in the autumn.

The great business of the state is agriculture. The soil produces abundantly cotton and tobacco, which are the staple commodities. The inhabitants also raise a plentiful supply of grain, grass, and fruit. They export cotton, tobacco, and flour in considerable quantities; also salt petre and many other articles. The principal commerce is carried on through the Tennessee and Cumberland rivers, and from them through the Ohio and Mississippi to New Orleans. This state also supplies Kentucky, Ohio, &c., with cotton for inland manufactures; and from East Tennessee considerable numbers of cattle are sent to the sea-ports on the Atlantic. It is probable that a new avenue to commerce will soon be opened, by means of roads or a canal, between the Tennessee river and the navigable waters of the Tombigbee. The western part of this state, lying between the Tennessee river and the Mississippi, belongs to the Chickasaw Indians; and a large district in the south-east part is included in the Cherokee country.

TENNESSEE RIDGE, mountains in the state of Tennessee, between the rivers Tennessee and Cumberland.

TENNIS, *n. s.* Supposed by Skinner to be so named from the word *tonex*, take it, hold it, or there it goes, used by the French when they drive the ball. A play at which a ball is driven with a racket.

Those four garrisons, issuing forth upon the enemy, will so drive him from one side to another, and tennis him amongst them, that he shall find no where safe to keep his feet in, nor hide himself.

Spenser on Ireland.

The barber's man hath been seen with him, and the old ornament of his cheek hath already stuffed tennis balls.

Shakspeare.

It can be no more disgrace to a great lord to draw a fair picture than to play at tennis with his page.

Peucham.

A prince, by a hard destiny, became a tennis ball to the blind goddess.

Howel's Vocal Forest.

The inside of the ueva is black like the walls of a

tennis court, that the rays falling upon the retina may not, by being rebounded thence upon the ueva, be returned again; for such a repercussion would make the sight more confused.

More against Atheism.

We conceive not a tennis-ball to think, and consequently not to have any volition or preference of motion to rest.

Locke.

We have no exedra for the philosophers adjoining to our tennis court, but there are ale-houses.

Arbutnot and Pope.

TENNIS, from Fr. *tenex*, or from Tennois, an ancient town of France. A play at which a ball is driven by a racket. The size of a tennis court is generally about ninety-six or ninety-seven feet by thirty-three or thirty-four. A line or net hangs exactly across the middle, over which the ball must be struck. Upon the entrance of a tennis court, there is a long gallery which goes to the dedans, that is a kind of front gallery, into which, whenever a ball is struck, it tells for a certain stroke. This long gallery is divided into different compartments or galleries, each of which has its particular name, as follows; from the line towards the dedans are the first gallery door, second gallery, and the last gallery, which is called the service side. From the dedans to the last gallery are the figures 1, 2, 3, 4, 5, 6, at a yard distance each, by which the chaces are marked. On the one side of the line are also the first gallery door, second gallery, and last gallery; which is called the hazard side. Every man struck into the last gallery on this side reckons for a certain stroke the same as the dedans. Between the second and this last gallery are the figures 1, 2, to mark the chaces on the hazard side. Over this long gallery, or these compartments, is a covering, called the pent-house, on which they play the ball from the service-side, in order to begin a set of tennis, from which it is called a service. When they miss putting the ball (so as to rebound from the pent-house) over a certain line on the service-side, it is deemed a fault, two of which are reckoned for a stroke. If the ball rolls round the pent-house, on the opposite side of the court, so as to fall beyond a certain line described for that purpose, it is called passe, reckons for nothing on either side, and the player must serve again. On the right hand side of the court from the dedans is the tambour, a part of the wall which projects, and is so contrived in order to make a variety in the stroke, and render it more difficult to be returned by the adversary; for, when a ball strikes the tambour, it varies its direction, and requires some extraordinary judgment to return it over the line. The last thing on the right hand side is called the grill, wherein if the ball is struck, it is also fifteen, or a certain stroke. The game of tennis is played by what they call sets; a set of tennis consists of six games; but if they play what is called an advantage set, two above five games must be won successively by one of the parties. When the player gives his service at the beginning of a set, his adversary is supposed to return the ball; and, whenever it falls after the first rebound untouched, the chace is called accordingly; for example, if the ball at the figure 1, the chace is called at a yard, that is to say, at a yard from the dedans: this chace

remains till a second service is given; and if the player on the service-side lets the ball go after his adversary returns it, and if the ball falls on or between any of these figures or chaces, they must change sides, there being two chaces; and he who then will be on the hazard side, must play to win the first chace: which if he wins by striking the ball so as to fall, after its first rebound, nearer to the dedans than the figure 1, without his adversary's being able to return it from its first hop, he wins a stroke, and then proceeds in like manner to win the second chace, wherever it should happen to be. If a ball falls on the line with the first gallery door, second gallery, or last gallery, the chace is likewise called at such or such a place, naming the gallery door, &c. When it is just put over the line, it is called a chace at the line. If the player on the service-side returns a ball with such force as to strike the wall on the hazard-side so as to rebound, after the first hop over the line, it is also called a chace at the line. The chaces on the hazard-side proceed from the ball being returned either too hard or not quite hard enough; so that the ball, after its first rebound, falls on this side of the blue line, or line which describes the hazard-side chaces; in which case it is a chace at 1, 2, &c., provided there is no chace depending. When they change sides, the player, in order to win this chace, must put the ball over the line any where, so that his adversary does not return it. When there is no chace on the hazard-side, all balls put over the line from the service-side, without being returned, reckon for a stroke. This game is marked in a singular manner. The first stroke is called fifteen, the second thirty, the third forty, and the fourth game, unless the players get four strokes each; in that case, instead of calling it forty all, it is called deuce; after which, as soon as any stroke is got, it is called advantage; and, in case the stroke becomes equal again, deuce again, till one or the other gets two strokes following, which win the game. Although but one ball at a time is played with, a number of balls are made use of at this game to avoid trouble, and are handed to the players in baskets for that purpose; by which they can play as long as they please, without ever having occasion to look for a ball.

TEN'ON, *n. s.* Fr. *tenon*. The end of a piece of timber cut to be fitted into another piece.

Such variety of parts, solid with hollow; some with cavities as mortices to receive, others with *tenons* to fit them. *Ray.*

The *tenant* saw, being thin, hath a back to keep it from bending. *Moxon's Mechanical Exercises.*

TENOR, *n. s.* Lat. *tenor*; Fr. *teneur*. Continuity of state; constant mode; currency; course; drift; in music, see below.

We might perceive his words interrupted continually with sighs, and the *tenor* of his speech not knit together to one constant end, but dissolved, in itself, as the vehemency of the inward passion prevailed. *Sidney.*

When the world first out of chaos sprang,
So smiled the days and so the *tenor* ran
Of their felicity; a spring was there,
An everlasting spring the jolly year

Led round in his great circle; no wind's breath
As now did smell of winter or of death. *Crashaw.*

By the stern brow and waspish action,
Which she did use as she was writing of it,
It bears an angry *tenor*. *Shakspeare. As you like it.*

The treble cutteth the air too sharp to make the sound equal; and therefore a mean or *tenor* is the sweetest part. *Bacon's Natural History.*

Water and air he for the *tenor* chose,
Earth made the base, the treble flame arose. *Cowley.*

Still I see the *tenor* of man's woe
Held on the same, from woman to begin. *Milton.*

Inspire my numbers,
Till I my long laborious work complete,
And add perpetual *tenor* to my rhimes,
Deduced from Nature's birth to Cæsar's times.

Dryden.

Can it be poison! poison 's of one *tenor*,
Or hot, or cold. *Id. Don Sebastian.*

Does not the whole *tenor* of the divine law positively require humility and meekness to all men?

Sprat.

Reading it must be repeated again and again, with a close attention to the *tenor* of the discourse, and a perfect neglect of the divisions into chapters and verses. *Locke.*

There is so great an uniformity amongst them, that the whole *tenor* of those bodies, thus preserved, clearly points forth the month of May.

Woodward's Natural History.

In such lays as neither ebb nor flow,
Correctly cold, and regularly low,
That, shunning faults, one quiet *tenor* keep,
We cannot blame indeed—but we may sleep. *Pope.*

TENOR, or **TENOUR**, the purport or content of a writing or instrument in law, &c.

TENOR, in music, the first mean or middle part, or that which is the ordinary pitch of the voice, when neither raised to a treble nor lowered to a bass. See **TENOUR**.

TENOS, **TINE**, or **ISTENDIL**, a pleasant and fertile island of the Cyclades group, in the Grecian archipelago, between Myconi and Andros. Its circumference is about thirty-four miles; its population nearly 25,000 souls, almost all Greeks. The surface is hilly, and covered with rocks, but the soil is well cultivated and very fertile. The chief products are silk, wine, figs, oranges, and honey. The island has no good harbour. St. Nicolò is the chief town.

TENSE, *adj.* } Lat. *tensus*. Stretched;
TENSE'NESS, *n. s.* } stiff; not lax: tenseness is
TEN'SIBLE, *adj.* } contraction; tension: ten-
TEN'SILE, } sible, and tensile, capable
TEN'SION, *n. s.* } of extension: tension, the
TEN'SIVE, *adj.* } act of stretching, or state
TEN'SURE, *n. s.* } of being stretched: this
also is the meaning of *tensure*: tense is giving a sense of stiffness.

All bodies ductile and *tensile*, as metals that will be drawn into wires, have the appetite of not discontinuing. *Bacon.*

Gold is the closest and therefore the heaviest of metals, and is likewise the most flexible and *tensile*. *Id.*

This motion upon pressure, and the reciprocal thereof, motion upon *tensure*, we call motion of liberty, which is, when any body being forced to a prternatural extent restoreth itself to the natural. *Id.*

All bodies, ductile and *tensile*, as metals, that will be drawn into wires; wool and tow, that will be

drawn into yarn or thread; have in them the appetite of not discontinuing strong, which maketh them follow the force that pulleth them out, and yet so as not to discontinue or forsake their own body. *Id.*

For the free passage of the sound into the ear, it is requisite that the tympanum be *terse*, and hard stretched, otherwise the laxness of the membrane will certainly dead and damp the sound. *Holder.*

It can have nothing of vocal sound, voice being raised by stiff *tension* of the larynx; and, on the contrary, this sound by a relaxed posture of the muscles thereof. *Id.*

Still are the subtle strings in *tension* found,
Like those of lutes, to just proportion wound
Which of the air's vibration is the force.

Blackmore.

Should the pain and *tenseness* of the part continue, the operation must take place.

Sharp's Surgery.

From cholera is a hot burning pain; a beating pain from the pulse of the artery; a *tensive* pain from distension of the parts by the fulness of humours.

Floyer on Humours.

TENSE, *n. s.* Fr. *temps*; Lat. *tempus*. In grammar, tense, in strict speaking, is only a variation of the verb to signify time.

As foresight, when it is natural, answers to memory; so when methodical it answers to reminiscence, and may be called forecast; all of them expressed in the *tenses* given to verbs. Memory saith, I did see; reminiscence, I had seen; foresight, I shall see; forecast, I shall have seen. *Grew.*

Ladies, without knowing what *tenses* and participles are, speak as properly and as correctly as gentlemen. *Locke.*

He should have the Latin words given him in their first case and *tense*, and should never be left to seek them himself from a dictionary. *Watts.*

TENSE, in grammar, an inflection of verbs, whereby they are made to signify or distinguish the circumstance of time in what they affirm. See GRAMMAR.

TENT, *n. s.* & *v. a.* Fr. *tente*. A roll of lint put into a sore: to search as with such a roll.

Modest doubt is called

The beacon of the wise; the *tent* that searches
To the bottom of the worst.

Shakespeare. Troilus and Cressida.

I have some wounds upon me, and they smart.

—Well might they fester 'gainst ingratitude,
And *tent* themselves with death. *Id. Coriolanus.*

A declining orifice keep open by a small *tent* dipt in some medicaments, and after digestion withdraw the *tent*, and heal it. *Wiseman's Surgery.*

Some surgeons, possibly against their own judgments, keep wounds *tented*, often to the ruin of their patient. *Wiseman.*

TENT, *n. s.* & *v. n.* } Fr. *tente*; Lat. *tento-*
TENTED. *adj.* } *rium*: A soldier's move-

able lodging-place: to lodge as in a tent: covered or furnished with tents.

Because of the same craft he wrought with them;
for by occupation they were *tent* makers.

Acts xviii. 23.

The Turks, the more to terrify Corfu, taking a hill not far from it, covered the same with *tents*.

Knolles.

These arms of mine till now have used
Their dearest action in the *tented* field.

Shakespeare. Othello.

The smiles of knaves
Tent in my cheeks, and schoolboy's tears take up
The glasses of my sight. *Shakespeare. re.*

He saw a spacious plain, whereon
Were *tents* of various hue: by some were herds
Of cattle grazing. *Milton's Paradise Lost.*

To Chassis' pleasing plains he took his way,
There pitched his *tents*, and there resolved to stay.
Dryden.

The foe deceived, he passed the *tented* plain,
In Troy to mingle with the hostile train.

Pope's Odyssey.

A TENT, in war, is a pavilion or portable house. Tents are made of canvas, for officers and soldiers to lie under when in the field. The size of the officers' tents is not fixed; some regiments have them of one size and some of another; a captain's tent and marquee is generally ten feet and a half broad, fourteen deep, and eight high; the subalterns' are a foot less; the major's and lieutenant-colonel's a foot larger; and the colonel's two feet larger. The subalterns of foot lie two in a tent, and those of horse but one. The tents of private men are six feet and a half square, and five feet high, and hold five soldiers each. The tents for horse are seven feet broad and nine feet deep; they hold likewise five men and their horse accoutrements.

TENT, in surgery, a roll of lint made into the shape of a nail with a broad flat head, chiefly used in deep wounds and ulcers. They are of service, not only in conveying medicines to the most intimate recesses and sinuses of the wound, but to prevent the lips of the wound from uniting before it is healed from the bottom; and by their assistance grumous blood, sordes, &c. are readily evacuated.

TENTATIVE, *adj.* } Fr. *tentative*; Lat.
TENTATION, *n. s.* } *tento*. Trying; essaying: trial; temptation.

The first delusion Satan put upon Eve, and his whole *tentation*, when he said, Ye shall not die, was, in his equivocation, You shall not incur present death. *Browne's Vulgar Errors.*

This is not scientific, but *tentative*. *Berkley.*

TENTER, *n. s.*, *v. a.*, & *v. n.* Lat. *tendo*, *tentus*. A hook on which things are stretched: 'to be on the tenters' is to be on the stretch: be in difficulties: to tenter is to stretch by hooks: admit extension.

A blown bladder pressed riseth again; and when leather or cloth is *tentered*, it springeth back.

Bacon's Natural History.

Woollen cloth will *tenter*, lincn scarcely. *Bacon.*

In all my past adventures,
I ne'er was set so on the *tenters*;
Or taken tardy with dilemma,
That every way I turn does hem me. *Hudibras.*

TENTER, TRIER, or PROVER, a machine used in the cloth manufactory, to stretch out the pieces of cloth, stuff, &c., or only to make them even and set them square. It is usually about four feet and a half high, and for length exceeds that of the longest piece of cloth. It consists of several long square pieces of wood, placed like those which form the barriers of a manege; so, however, as that the lower cross pieces of wood may be raised or lowered as is found requisite, to be fixed at any height by means of pins. Along the cross pieces, both the upper and under one, are hooked nails, called tenter-hooks, driven in from space to space.

TENTER, TO PUT A PIECE OF CLOTH ON THE. While the piece is yet quite wet, one end is fastened to one of the ends of the tenter; then it is pulled by force of arms towards the other end, to bring it to the length required; that other end being fastened, the upper list is hooked on to the upper cross-piece, and the lowest list to the lowest cross-piece, which is afterwards lowered by force, till the piece have its desired breadth. Being thus well stretched, both as to length and breadth, they brush it with a stiff hair-brush, and thus let it dry. Then they take it off; and, till they wet it again, it will retain the length and breadth the tenter gave it.

TENTERDEN, a market-town in Tenterden hundred, lathe of Scray, Kent, five miles east by south from Cranbrook, and fifty-seven east by south of London. The church, standing at the north end of the town, has a lofty steeple, on which formerly was a beacon, for alarming the country in case of invasion. Here are two chapels for dissenters, a free-school, a town-hall in which assemblies are occasionally held, and a market-house. At the first introduction of the woollen manufacture, this place had a considerable trade in weaving, but at present the grazing business is the chief occupation of its inhabitants. This is a member of the cinque ports, and is annexed to the town of Rye; the corporation consists of a mayor, twelve jurats, and twelve common-councilmen. Market on Friday. Fairs, first Monday in May, for cattle and pedlary.

TENTH, AND FIRST FRUITS OF SPIRITUAL PREFERMENTS, a branch of the king's revenue. See **REVENUE.** These were originally a part of the papal usurpations over the clergy of this kingdom; which were annexed to the revenue of the crown. By statute 26 Hen. VIII. c. 3 (confirmed by stat. 1 Eliz. c. 4) queen Anne granted her royal charter, which was confirmed by the stat. 2 Anne c. 11, whereby all the revenue of first fruits and tenths is vested in trustees for ever to form a perpetual fund for the augmentation of poor livings. This is usually called Queen Anne's bounty; which has been still farther regulated by subsequent statutes.

TENTHREDO, the saw-fly, a genus of insects belonging to the order of hymenoptera. The mouth is furnished with jaws, which are horny, arched, dentated within; the right jaw being obtuse at the apex; the lip cylindrical, trifid; there are four feelers, unequal and filiform; the wings are plain and turned; the sting consists of two serrated laminæ, and the scutellum of two grains placed at a distance. Gmelin mentions 143 species. These insects are not very shy. Some by means of their saw deposit in the buds of flowers, others on the twigs of trees or shrubs, eggs from which are produced caterpillars. The implement with which they are armed is nowise formidable; as it appears only destined to the purpose of depositing their eggs.

TENTZELIUS (William Ernest), a learned German, born at Armstadt in Thuringia, in 1659. He wrote, 1. *Saxonia Numismatica*, in 4 vols.; and 2. *Supplementum Historiæ Gothanæ*, 3 tom. 4to.—Moreri.

TENUITY, n. s. } Fr. *tenuité*; Lat. *tenu-*
TENUOUS, adj. } *itas, tenuis.* Thinness;

exility; smallness; meanness: the adjective corresponding.

Firs and pines mount of themselves in height without side boughs; partly heat, and partly *tenuity* of juice, sending the sap upwards.

Bacon's Natural History.

The *tenuity* and contempt of clergymen will soon let them see what a poor carcass they are, when parted from the influence of that supremacy.

King Charles.

Another way of their attraction is by a *tenuous* emanation, or continued effluvia, which after some distance retracteth unto itself.

Browne's Vulgar Errors.

Consider the divers figurings of the brain; the strings or filaments thereof; their difference in *tenuity*, or aptness for motion. *Glanville's Scrysis.*

Aliment, circulating through an animal body, is reduced to an almost imperceptible *tenuity* before it can serve animal purposes. *Arbuthnot.*

At the height of four thousand miles the ather is of that wonderful *tenuity*, that if a small sphere of common air, of an inch diameter, should be expanded to the thinness of that ather, it would more than take up the orb of Saturn; which is many million times bigger than the earth. *Bentley.*

TENURE, n. s. Fr. *tenure*; Lat. *teno.* The legal manner in which a tenement is held.

The service follows the *tenure* of lands; and the lands were given away by the kings of England to those lords. *Spenser.*

The uncertainty of *tenure*, by which all worldly things are held, ministers very unpleasant meditation. *Rowleigh.*

Man must be known, his strength, his state,
And by that *tenure* he holds all of fate. *Dryden.*

TENURE, in the English law, signifies the manner whereby lands or tenements are held, or the service that the tenant owes to his lord. Almost all the real property of England is by the policy of the law supposed to be granted by, dependent upon, and holden of, some superior lord, by and in consideration of certain services to be rendered to the lord by the tenant or possessor of this property. The thing holden is therefore stiled a tenement, the possessors thereof tenants, and the manner of their possession a *tenure*. Thus all the lands of the kingdom are supposed to be holden, mediately or immediately, of the king; who is stiled the lord paramount, or above all. Such tenants as held under the king immediately, when they granted out portions of the lands to inferior persons, became also lords with respect to those inferior persons, as they were still tenants with respect to the king; and, thus partaking of a middle nature, were called mesne or middle lords. All *tenures* being thus derived from the king, those that held immediately under him, in right of his crown and dignity, were called his tenants in capite, or in chief. 'Tenements are of two kinds, frank-tenement and villenage. And, of frank-tenements, some are held freely in consideration of homage and knight-service; others in free-socage, with the service of fealty only. And again, of villenages, some are pure, and others privileged. He that holds in pure villenage shall do whatsoever is commanded him, and always be bound to an uncertain service. The other kind of villenage is called villein-socage; and these villein-socmen do villein-services, but such as are cer-

tain and determined.' Of which the sense seems to be as follows: first, where the service was free, but uncertain, as military service with homage, that tenure was called the tenure in chivalry, *per servitium militare*, or by knight-service. Secondly, where the service was not only free, but also uncertain, as by fealty only, by rent and fealty, &c., that tenure was called *liberum socagium*, or free soccage. These were the only free holdings or tenements; the others were villenous or servile: as, thirdly, where the service was base in its nature, and uncertain as to time and quantity, the tenure was *purum villenagium*, absolute or pure villenage. Lastly, where the service was base in its nature, but reduced to a certainty, this was still villenage, but distinguished from the other by the name of privileged villenage, *villanagium privelegiatum*; or it might still be called soccage (from the uncertainty of its services), but degraded by their baseness into the inferior title of *villanum socagium*, villein-soccage. 1. The military tenure, or that by knight-service, was done away by stat. 12 Car. II. For an account of this species of tenure see FEUDAL SYSTEM, and KNIGHT-SERVICE; and for its incidents, see RELIEF, PRIMER-SEISIN, WARDSHIP, MARRIAGE, FINES, and ESCHEAT. 2. The second species of tenure or free-soccage, not only subsists to this day, but has in a manner absorbed and swallowed up (since the statute of Charles II.) almost every other species of tenure. See SOCCAGE. The other grand division of tenure, mentioned by Bracton, is that of villenage, as contradistinguished from *liberum tenementum*, or frank-tenure. And this he subdivides into two classes, pure and privileged villenage; whence have arisen two other species of our modern tenures. 3. From the tenure of pure villenage have sprung the present copyhold tenures, or tenure by copy of court-roll at the will of the lord. See MANOR. Two main principles are held to be the supporters of a copyhold tenure, and without which it cannot exist: 1. That the lands be parcel of and situate within that manor under which it is held. 2. That they have been demised, or demisable, by copy of court-roll immemorially. For immemorial custom is the life of all tenures by copy; so that no new copyhold can, strictly speaking, be granted at this day. In some manors, where the custom hath been to permit the heir to succeed the ancestor in his tenure, the estates are styled copyholds of inheritance; in others, where the lords have been more vigilant to maintain their rights, they remain copyholds for life only; for the custom of the manor has in both cases so far superseded the will of the lord, that, provided the services be performed or stipulated for by fealty, he cannot in the first instance refuse to admit the heir of the tenant upon his death; nor, in the second, can he remove his present tenant so long as he lives, though he holds nominally by the precarious tenure of his lord's will. The fruits and appendages of a copyhold tenure, that it hath in common with free tenures, are fealty, services (as well in rents as otherwise), reliefs, and escheats. The two latter belong only to copyholds of inheritance; the former to those for life also. But, besides these, copyholds have also fieriots, wardship, and fines. Fieriots, which

are agreed to be a Danish custom, are a render of the best beast or other good (as the custom may be) to the lord on the death of the tenant. This is plainly a relic of villein tenure; there being originally less hardship in it, when all the goods and chattels belonged to the lord, and he might have seized them even in the villein's lifetime. These are incident to both species of copyhold; but wardship and fines to those of inheritance only. Wardship, in copyhold estates, partakes both of that in chivalry and that in soccage. Like that in chivalry, the lord is the legal guardian, who usually assigns some relation of the infant tenant to act in his stead; and he, like guardian in soccage, is accountable to his ward for the profits. Of fines, some are in the nature of primer-seisins, due on the death of each tenant; others are mere fines for alienations of the lands; in some manors only one of those sorts can be demanded, in some both, and in others neither. They are sometimes arbitrary and at the will of the lord, sometimes fixed by custom; but, even when arbitrary, the courts of law, in favor of the liberty of copyholders, have tied them down to be reasonable in their extent; otherwise they might amount to disherison of the estate. No fine therefore is allowed to be taken upon descents and alienations (unless in particular circumstances) of more than two years improved value of the estate. From this instance we may judge of the favorable disposition that the law of England (which is a law of liberty) hath always shown to this species of tenants, by removing, as far as possible, every real badge of slavery from them, however some nominal ones may continue. It suffered custom very early to get the better of the express terms upon which they held their lands; by declaring that the will of the lord was to be interpreted by the custom of the manor; and, where no custom has been suffered to grow up to the prejudice of the lord, as in this case of arbitrary fines, the law itself interposes in an equitable method, and will not suffer the lord to extend his power so far as to disinherit the tenant. 4. There is yet a fourth species of tenure, described by Bracton, under the name sometimes of privileged villenage, and sometimes of villein-soccage. See VILLENAGE, PRIVILEGED. There is still one other species of tenure, reserved by the statute of Charles II., which is of a spiritual nature, and called the tenure in FRANK ALMOIGN; see that article.

TEOS, one of the twelve Ionian cities, was situated on the south side of the Ionian peninsula, and distinguished by being the birth place of the poet Anacreon and the historian Hecataeus.

TEPID, *adj.* } Latin, *tepidus*. Luke-
TEPOR, *n. s.* } warm; warm in a small
degree: the noun substantive corresponding.

The tepid caves, and fens, and shores,
Their brood as numerous hatch. *Milton.*
He with his tepid rays the rose renews,
And licks the dropping leaves, and dries the dew. *Dryden.*

Such things as relax the skin are likewise sudorific; as warm water, friction, and tepid vapours.

Arbuthnot.
The small-pox, mortal during such a season, grew more favourable by the tepor and moisture in April. *Id.*

TEQUENDAMA, CATARACT OF, a remarkable fall of the Rio Bogota, in South America. This river receives numerous tributary streams as it passes over the plain of Bogota, and it is about 140 feet in breadth, a short distance above the fall. Approaching the crevice through which it dashes, its breadth is diminished to thirty-five; when, with accumulated force, it rushes down a perpendicular rock at two bounds, to the astonishing depth of 600 feet, into a dark unfathomable gulf, out of which the river again issues under the name of Rio Meta, and continues its course, by an immense descent, till it joins the Magdalena. In the fall of this river may be observed a strange variety of climate. The plain of Bogota is covered with crops of wheat, with oaks, elms, and other productions of a temperate region. At the foot of the fall are seen the palms of the equinoctial low lands. The face of the rock, which finishes and borders the vast plain of Bogota, near the cataract, is so steep that it takes three hours to descend from the river Funza to the Rio Meta; and the basin or gulf cannot be approached very close, as the rapidity of the water, the deafening noise of the fall, and dense mass of vapor, render it impossible to get nearer the edges of the abyss than 400 or 500 feet. The loneliness of the spot, the dreadful noise, and the beauty of the vegetation, render this situation one of the wildest and most picturesque scenes in the whole world.

TERAPHIM, or THERAPHIM, a word in the Hebrew language, which has exercised much the ingenuity of the critics. It occurs thirteen or fourteen times in the Old Testament, and is commonly interpreted idols.

TERCE, n. s. Fr. *tierce*; Lat. *triens*. A vessel containing forty-two gallons, or the third part of a butt or pipe of wine.

In the poet's verse

The king's fame lies, go now deny his *tierce*.

Ben Jonson.

TERCERA, an island forming part of the group of the Azores, near the coast of Africa. The Portuguese gave this name to it from its being the third in succession that was discovered. In consequence of its central situation, and the safety of the roadstead at Angra, it has been made the seat of government; and it is about fifty-four miles in circumference, surrounded with steep rocks, which render it inaccessible, except at a few points, which are strongly fortified. The interior is extremely agreeable, the summits of the mountains consisting, for the most part, of beautiful and fertile plains, abundantly supplied with fine water. Vines are cultivated, but the wine is by no means excellent. Agriculture and pasturage are the chief employments; and fruit, grain, and cattle, are in such abundance, that the population, though amounting to 50,000 souls, subsist in the greatest plenty, and export corn to Lisbon. The only two places of consequence are Angra and Praya.

TEREBELLA, the piercer, in entomology, a genus of insects belonging to the class of vermes and order of molusca. The body is filiform, the mouth placed before; the preputium puts forth a pedunculated tubulous gland. There are several

capillary tentacula about the mouth. There are ten species.

TEREBIN'THINATE, adj. } Fr. *terebin-*
TEREBIN'THINE. } *thine*; Lat. *te-*
rebinthum. Consisting of turpentine; mixed with turpentine.

Salt serum may be evacuated by urine, by *terebinthinas*: as tops of pine in all our ale. *Floyer.*

TEREBRATULÆ, in zoology, or rather ichthyology, a species of anomia which have been supposed not to exist now but as petrified shells. See **ANOMIA**. This, however, is a mistake. The anomia is an inhabitant of every region, and has existed in every age.

TEREBRATE, v. a. } Latin, *terebro*. To
TEREBRATION, n. s. } bore; perforate; pierce:
the noun substantive corresponding.

Terebration of trees makes them prosper better; and also it maketh the fruit sweeter and better.

Bacon.

Consider the threefold effect of Jupiter's trisulc, to burn, discuss, and *terebrate*.

Brown's Vulgar Errors.

Earth-worms are completely adapted to their way of life, for *terebrating* the earth and creeping.

Derham.

TEREDO, in entomology, a genus of vermes belonging to the order of testacea. The animal is a terebella; there are two valves, calcareous, hemispherical, and cut off before, and two lanceolated. The shell is tapering, bending, and capable of penetrating wood. There are only three species; viz. 1. *T. clava*, the nail worm. 2. *T. navalis*, the ship worm, has a very slender smooth cylindrical shell, inhabits the Indian seas, whence it was imported into Europe. It penetrates easily into the stoutest oak-planks, and produces dreadful destruction to the ships by the holes it makes in their sides; and it is to avoid the effects of this insect that vessels require sheathing. The head of this creature is coated with a strong armour, and furnished with a mouth like that of a leech; a little above this it has two horns which seem a kind of continuation of the shell; the neck is furnished with several strong muscles; the rest of the body is only covered by a very thin and transparent skin, through which the motion of the intestines is plainly seen by the naked eye. This creature is wonderfully minute when newly excluded from the egg, but it grows to the length of four or six inches, and sometimes more. When the bottom of a vessel, or any piece of wood which is constantly under water, is inhabited by these worms, it is full of small holes; but no damage appears till the outer parts are cut away. Then their shelly habitations come into view; in which there is a large space for enclosing the animal and surrounding it with water. There is an evident care in these creatures never to injure one another's habitations; by these means each case or shell is preserved entire. Dissection has shown that every individual has the parts of both sexes, and is therefore supposed to propagate by itself. 3. *T. utriculus*, the bottle worm.

TEREDON, in ancient geography, a town on the coast of the Arabic Gulf.—Dion Perieg.

TERENCE. See **TERENTIUS**.

TERENTIA, 1. the wife of Cicero, and mo-

ther of his son Marcus and his daughter Tulliola. While the orator was in Asia she behaved so ill that he divorced her. She afterwards married his enemy Sallust. 2. Terentia the wife of Mæcenas who behaved equally ill to that great man.

TERENTIANUS. See MAURUS.

TERENTIUS AFER (Publius or Terence), a celebrated comic poet of ancient Rome, born at Carthage in Africa. He was slave to Terentius Lucanus the senator, who gave him his liberty on account of his wit, his good mien, and great abilities. Terence, on his becoming a freedman, applied himself to the writing of comedies. Terence died while on a voyage into Greece, about the fifteenth year before the Christian era. There are six of his comedies extant, of which the best editions are the Elzevir one 1635, 12mo.; that cum integris notis Donati, et selectis variorum, 1686, 8vo.; Westervhiovius's, in 2 vols. 4to. 1726; and that of Bentley the same year, 4to. A very good English translation was published in 4to. 1768, by Mr. Colman.

TERGIVERSATION, *n. s.* Lat. *tergum* and *verso*. Shift; subterfuge; evasion.

Writing is to be preferred before verbal conference, as being freer from passions and tergiversations.

Bishop Bramhall.

The colonel, after all his tergiversations, lost his life in the king's service. *Clarendon.*

TERLIZZI, a large town of Italy, in the south-east of Naples. Its population is said to amount to 8000, and it stands on the high road leading from the town of Bari on the coast, in a north-west direction, across the Ofanto or Aufidus. This part of Italy, the ancient Apulia, is thinly peopled; and Terlizzi has few manufactures. It stands twenty miles south of the site of Cannæ, and sixty north-west of Tarentum.

TERM, *n. s. & v. a.* } Lat. *terminus*. Limit;
TERM'LESS, *adj.* } boundary: hence words
TERM'LY, *adv.* } expressing a certain
TERM'ER, *n. s.* } thing or meaning; language; condition; limited time: for legal terms see below: to term is, to name; call; describe: the adjective corresponding: termly is, term by term: a termier is one who travels up to the term.

Would curses kill, as doth the mandrake's groan, I would invent as bitter searching terms, As curst, as harsh, as horrible to hear. *Shakspeare.*

I am thy father's spirit,

Doomed for a certain term to walk the night. *Id.*

These betraying lights look not up towards termless joys, nor down towards endless sorrows. *Raleigh.*

To apply notions philosophical to plebeian terms, or to say, where the notions cannot be fitly reconciled, that there wanted a term, or nomenclature for it, be but shifts of ignorance. *Bacon.*

Corruption is a reciprocal to generation; and they two are as nature's two terms or boundaries, and the guides to life and death. *Id. Natural History.*

The clerks are partly rewarded by that means also, besides that termly fee which they are allowed. *Bacon.*

Nor have my title leaf on post or walls, Or in cleft sticks advanced to make calls For termers, or some clerk-like serving man.

Ben Jonson.

The term suiters may speed their business: for the end of these sessions delivereth them space enough to overtake the beginning of the terms. *Carew.*

God to Satan first his doom applied

Though in mysterious terms. *Milton.*

Too long vacation hastened on his term. *Id.*

Those men employed as justices daily in term time consult with one another. *Hale.*

What are these to those vast heaps of crimes

Which terms prolong? *Dryden.*

Live, though unhappy, live on any terms. *Id.*

In painting, the greatest beauties cannot always be expressed for want of terms. *Id.*

Men term what is beyond the limits of the universe imaginary space, as if nobody existed in it. *Locke.*

Those parts of nature into which the chaos was divided, they signified by dark and obscure names, which we have expressed in their plain and proper terms. *Burnet.*

We flattered ourselves with reducing France to our own terms by the want of money, but have been still disappointed by the great sums imported from America. *Addison.*

Why should Rome fall a moment ere her time?

No; let us draw her term of freedom out

In its full length, and spin it to the last. *Id.*

Did religion bestow heaven, without any terms or conditions, indifferently upon all, there would be no infidel. *Bentley.*

Had the Roman tongue continued vulgar, it would have been necessary, from the many terms of art required in trade and in war, to have made great additions to it. *Swift.*

TERM, in law, is generally taken for a limitation of time or estate; as a lease for term of life or years. Term is more particularly used for that time wherein our courts of justice are open; in opposition to which the rest of the year is called vacation.

TERM, in grammar, denotes some word or expression in a language. The word term (from terminus) is borrowed metaphorically, by the grammarians and philosophers, from the measurers or surveyors of lands: as a field is defined and distinguished by its termini or limits, so is a thing or matter spoken of by the word or term it is denoted by.

TERM, in the arts, or term of art, is a word which, besides the literal and popular meaning which it has or may have in common language, bears a further and peculiar meaning in some art or science.

The TERMS in law above enumerated are not observed by the high court of parliament, the chancery, and inferior courts; only the courts of king's bench, common pleas, and exchequer, which are the highest courts at common law. These terms are supposed by Mr. Selden to have been instituted by William the Conqueror; but Sir H. Spelman hath shown that they were gradually formed from the canonical constitutions of the church; being no other than those leisure seasons of the year which were not occupied by the great festivals or fasts, or which were not liable to the general avocations of rural business. Throughout all Christendom, in very early times, the whole year was one continued term for hearing and deciding causes.

Oxford terms.—These are four; which begin and end as below:—

LENT-TERM

Begins . . . January 14th.

Ends . . . Saturday before Palm Sunday.

EASTER-TERM

Begins . . . Wednesday after Low Sunday.
Ends . . . Thursday before Whit-Sunday.

TRINITY-TERM

Begins . . . Wednesday after Trinity-Sunday.
Ends . . . Saturday after the Act.

MICHAELMAS-TERM

Begins . . . October 10th.
Ends . . . December 16th.

N. B. The Act is the first Monday after the 6th of July. When the day of the beginning or ending happens on a Sunday, the terms begin or end the day after.

Cambridge terms.—These are three, as below :

LENT-TERM

Begins . . . January 13th.
Ends . . . Friday before Palm-Sunday.

EASTER-TERM

Begins . . . Wednesday after Low-Sunday.
Ends . . . Friday after Commencement.

MICHAELMAS-TERM

Begins . . . October 10th.
Ends . . . December 16th.

N. B. The commencement is the first Tuesday in July. There is no difference on account of the beginning or ending being Sunday.

TERMS, IRISH. In Ireland the terms are the same as at London, except Michaelmas term, which begins October 13th, and adjourns to November 3rd, and thence to the 6th.

TERMS, SCOTTISH. The court of session has two terms, the winter and summer. The winter begins on the 12th of November, and ends the 11th of March, only there is a recess of three weeks at Christmas. The summer term commences on the 12th of May, and ends the 11th of July. The court of exchequer has four terms. 1. Candlemas term begins January 15th, and ends February 3rd. 2. Whitsuntide term begins May 12th, and ends June 2nd. 3. Lammas term begins June 17th, and ends July 5th. 4. Martinmas term begins November 24th, and ends December 20th.

TERMAGANT, adj. & n. s. } Sax. *týr* and
TERMAGANCY, n. s. } *magan*, emi-
nently powerful; or *týr*, taken as a name of Mars. Tumultuous; turbulent: a turbulent person: turbulence; tumultuous violence.

'Twas time to counterfeit, or that hot *termagant*
Scot had paid me scot and lot too.

Shakspeare. Henry IV.

I would have such a fellow whipt for o'erdoing
Termagant; it outhers Herod. *Id. Hamlet.*

For zeal's a dreadful *termagant*,
That teaches saints to tear and rant. *Hudibras.*

She threw his periwig into the fire: Well, said
he, thou art a brave *termagant*. *Tatler.*

The eldest was a *termagant*, imperious, prodigal,
profligate wench. *Arbutnot's History of John Bull.*

The sprites of fiery *termagants* in flame
Mount up, and take a salamander's name. *Pope.*

By a violent *termagancy* of temper, she may never
suffer him to have a moment's peace. *Barker.*

TERMES, in entomology, a genus of insects belonging to the order of aptera according to Linnæus; but by others it is arranged more pro-

perly under the neuroptera. The mouth has two horny jaws; the lip is horny and quadrifid, the lacinie being linear and acute; there are four feelers, which are equal and filiform. The antennæ are moniliform in most species, and the eyes two. There are eight species according to Gmelin; viz. *T. arda*, *Capensis*, *destructor*, *divinatorius*, *fatalis*, *fatidicus*, *mordax*, and *pulsatorius*. But, as Gmelin has followed the classification of Linnæus in arranging the termes under the order of aptera, it is not improbable that several of those which are mentioned as species of the termes may belong to a different genus. It will be sufficient here to describe the *fatalis*, which we are enabled to do from very accurate information.

T. fatalis bellicosus, or the white ant, is of a yellow color above; the wings also yellowish; the costa is ferruginous; the stemmata are near the eyes, the central point being somewhat prominent. Of the white ant we have a very curious and interesting description in the Philosophical Transactions for 1781 by Mr. Henry Smeathman of Clement's Inn. According to this account the works of these insects surpass those of the bees, wasps, beavers, and other animals, as much at least as those of the most polished European nations exceed those of the least cultivated savages. In the interior construction of their habitations they appear greatly to exceed any work of human construction. The most striking parts of these structures are the royal apartments, the nurseries, magazines of provisions, arched chambers and galleries, with their various communications; the ranges of gothic-shaped arches, projected, and not formed by mere excavation, some of which are two or three feet high, but which diminish rapidly like the arches of aisles in perspective; the various roads, sloping staircases, and bridges, consisting of one vast arch, and constructed to shorten the distance between the several parts of the building, which would otherwise communicate only by winding passages. In some parts near Senegal their number, magnitude, and closeness of situation, make them appear like the villages of the natives. But these and many other curious instances of the great sagacity and powers of these insects cannot be understood without viewing the plates in which their feeble frames, and comparatively stupendous works, are delineated. See Philosophical Transactions above referred to. There are three distinct ranks among them. These are, first, the laborers, or working insects; next the soldiers, or fighting order, who do no kind of labor, and are about twice as long as the former, and equal in bulk to about fifteen of them; and, lastly, the winged or perfect insects, which may be called the nobility or gentry of the state; for they neither labor nor fight, being scarcely capable even of self-defence. 'These only are capable of being elected kings or queens; and nature has so ordered it that they emigrate within a few weeks after they are elevated to this state, and either establish new kingdoms or perish within a day or two.' The first order, the working insects, are most numerous, being in the proportion of 100 to one of the soldiers. In this state they are about a quarter of an inch long,

and twenty-five of them weigh about a grain; so that they are not so large as some of our ants. The second order, or soldiers, have a very different form from the laborers, and have been by some authors supposed to be the males, and the former neuters; but they are, in fact, the same insects as the foregoing, only they have undergone a change of form and approached one degree nearer to the perfect state. They are now much larger, being half an inch long, and equal in bulk to fifteen of the laborers. The third order, or the insect in its perfect state, varies its form still more than ever. The head, thorax, and abdomen, differ almost entirely from the same parts in the laborers and soldiers; and besides this the animal is now furnished with four fine large, brownish, transparent wings, with which it is, at the time of emigration, to wing its way in search of a new settlement. It differs so much from the other two that they have not hitherto been supposed to belong to the same community. In fact they are not to be discovered in the nest till just before the commencement of the rainy season; when they undergo the last change, which is preparative to the formation of new colonies. They are equal in bulk to two soldiers, and about thirty laborers; and, by means of the wings with which they are furnished, they roam about for a few hours; at the end of which time they lose their wings, and become the prey of innumerable birds, reptiles, and insects; while probably not a pair out of many millions of this unhappy race get into a place of safety, fulfil the first law of nature, and lay the foundation of a new community. In this state many fall into the neighbouring waters and are eaten with avidity by the Africans. The author found them delicate, nourishing, and wholesome, without sauce or other help from cookery than merely roasting them in the manner of coffee. The few fortunate pairs who happen to survive this annual massacre and destruction are represented by the author as being casually found by some of the laborers that are continually running about on the surface of the ground, and are elected kings and queens of new states. Those who are not so elected and preserved, certainly perish, and most probably in the course of the following day. By these industrious creatures the king and queen elect are immediately protected from their innumerable enemies, by enclosing them in a chamber of clay, where the business of propagation soon commences. Their 'voluntary subjects' then busy themselves in constructing wooden nurseries, or apartments entirely composed of wooden materials, seemingly joined together with gums. Into these they afterwards carry the eggs produced from the queen, lodging them there as fast as they can obtain them from her. After impregnation a very extraordinary change begins to take place in her person, or rather in her abdomen only. It gradually increases in bulk, and at length becomes of such an enormous size as to exceed the bulk of the rest of her body 1500 or 2000 times. She becomes 1000 times heavier than her consort, and exceeds 20,000 or 30,000 times the bulk of one of the laborers. In this state the matrix has a constant peristaltic or undulating motion; the consequence of which is

(as the author has counted them) the protrusion of 80,000 eggs in twenty-four hours.

TERMINALIA, in antiquity, feasts celebrated by the Romans in honor of the god Terminus.

TERMINALIA, in botany, a genus of plants belonging to the class of polygamia and order of monœcia. The male calyx is quinquepartite; there is no corolla; the stamina are ten. The hermaphrodite flower is the same with that of the male; there is one style; the fruit, which is a drupe or plum, is below, and shaped like a boat. There are two species; viz. 1. *T. Augustifolia*, the narrow-leaved, or benzoin plant; but though it has this name it does not yield benzoin. See **STYRAX**. 2. *T. Catappa*.

TERMINATE, *v. a. & v. n.* } Fr. *terminer* ;
TERMINATION, *n. s.* } Latin *termino*.
See TERM. To bound; limit; put an end to: be limited; or at an end: the noun substantive corresponding.

She speaks poniards, and every word stabs; if her breath were as terrible as her terminations, there were no living near her, she would infect to the north star.

Shakspeare.

It is not an idol *ratione termini*, in respect of *termination*; for the religious observation thereof is referred and subservient to the honour of God and Christ: neither is it such *ratione modi*, for it is kept holy by the exercise of evangelical duties.

White.

These are to be reckoned with the heathen, with whom you know we undertook not to meddle, treating only of the scripture-election *terminated* in those to whom the scripture is revealed.

Hammond.

Its earthly and salinous parts are so exactly dissolved, that its body is left imporous, and not discredited by atomical terminations.

Brown's Vulgar Errors.

Ere I the rapture of my wish renew,
 I tell you, then, it *terminates* in you.

Dryden's Aurengzebe.

Bodies that are solid, separable, *terminated*, and moveable, have all sorts of figures.

Locke.

TERMINI, in architecture, denotes a kind of statues or columns, adorned on the top with the figure of a man's, woman's, or satyr's head, as a capital; and the lower part ending in a kind of sheath or scabbard. Suidas thinks they should rather be called hermetes than termini, as they originated from the Athenian hermeses, which were used as ornaments, and not from the Roman termini, which were used as land-marks. See **HERMES**.

TERMINI, a considerable sea-port of Sicily, in the Val di Mazzara, on the north coast, and at the mouth of a river of this name. It stands on a rocky eminence, surrounded by a wall, and has, on the side of the sea, an old castle. The public establishments consist of a Monte di Pietà, two hospitals, a poor-house for females, several convents, and some rather richly ornamented churches. Here is a tolerable port, and the inhabitants have long been in the practice of exporting corn, olive oil, and other products. Though a place of some note in antiquity, it has at present few remains, but it has long been celebrated for its hot mineral springs. Inhabitants about 8700. Eighteen miles E. S. E. of Palermo. Long 13° 45' E., lat. 38° 5' N

TERMINTHUS, *n. s.* Greek *τέρμινθος*. A tumor.

Terminthus is of a blackish colour; it breaks, and within a day the pustule comes away in a slough.

Wiseman.

TERMINUS, in Pagan worship, an ancient deity among the Romans, who presided over the stones or land-marks called *termini*, which were held so sacred that it was accounted sacrilege to move them; and as the criminal became devoted to the gods it was lawful for any man to kill him. The worship of this deity was instituted by Numa Pompilius, who, to render land-marks, and consequently the property of the people, sacred, erected a temple on the Tarpeian mount to *Terminus*.

TERMIOVA, a town of Maritime Austria, in Istria, eighteen miles north-east of Pedena.

TERMITES. See **TERMES**.

TERMOLI. See **TERMINI**.

TERMUYDEN, a strong town of Holland, in the department of the Meuse and ci-devant province of Dutch Flanders, north-east of Sluys.

TERN, in ornithology. See **STERNA**.

TERNAI, the name given by Perouse to a very fine bay which he discovered on the coast of Tartary in lat. 45° 13' N., long. 135° 9' E. of Paris. The bottom is sandy, and diminishes gradually to six fathoms within a cable's length of the shore. The tide rises five feet; it is high water at eight hours fifteen minutes at full and change; and the flux and reflux do not alter the direction of the current at half a league from the shore.

TER'NARY, or } Latin *ternarius*, *ternio*.

TER'NION, *n. s.* } The number three.

These nineteen consonants stood in such confused order, some in *ternaries*, some in pairs, and some single.

Holder.

TERNATE, the northernmost of a chain of islands on the west coast of Gilolo, and formerly the seat of sovereignty over all the adjacent Molucca islands, Tidore, Baclian, Motir, and Machian. The first Mahometan sovereign of Ternate is said to have reigned from A. D. 1466 to 1486. In 1521 it was visited by the Portuguese, who took formal possession; but they were expelled in 1530. In 1579 it was touched at by Sir Francis Drake, who, according to the fashion of the day, took possession of it in the name of queen Elizabeth. Along with the kingdom of Portugal it devolved to the Spaniards, who lost Ternate in 1606; but retained a footing in the Molucca so late as 1663. In 1680 the Dutch compelled the sultan of Ternate to become tributary to them, and the princes of the other Moluccas were so thoroughly subdued that in the year 1778 the kings of Tidore and Baclian were deposed, and exiled to Batavia. It was taken from the Dutch in the course of the revolutionary war, but was restored at the peace of Amiens. It was again taken in August 1810, and was restored to the Dutch, with their other possessions in India, by the peace of Paris.

TERNAVASSO, a town of the French empire, in the department of the Po, and ci-devant province of Piedmont, six miles north-east of Carmagnola, and eight south of Chieri.

VOL. XXI.

TERNI, a town in the State of the Church, situated in a luxuriant valley, between two branches of the Nera. It has a cathedral and several churches, but no other public building of consequence. It is a place of antiquity, and still contains several interesting ruins. The cascades of the Eveline, called the *Caduta delle Marmore* are very fine. Population about 7000. Twelve miles south of Spalato, and forty-five north of Rome.

TERNSTROMIA, in botany, a genus of plants belonging to the class of polyandria and order of monogynia. The calyx is monophyllous and quinquepartite; the corolla is monopetalous, quinquepartite or sexpartite, globular, and bell-shaped; the berry is dry, bilocular, and valveless. There is only one species, viz. *T. meridionalis*.

TERPANDER, a celebrated Greek poet and musician. The Oxford marbles tell us that he was the son of Derdeneus of Lesbos, and that he flourished in the thirty-eighth year of these records; which nearly answers to the twenty-seventh Olympiad, and sixty-first year B. C. The marbles inform us likewise that he taught the nomes, or airs, of the lyre and flute, which he performed himself upon this last instrument in concert with other players on the flute. Several writers tell us that he added three strings to the lyre, which before his time had but four. See **LYRE**. Among the many signal services which *Terpander* is said to have done to music, none was of more importance than the notation that is ascribed to him for ascertaining and preserving melody, which before was traditional and wholly dependent on memory. The invention indeed of musical characters has been attributed by *Alypius* and *Gaudentius*, two Greek writers on music, and upon their authority by *Boethius*, to *Pythagoras*, who flourished full two centuries after *Terpander*. But *Plutarch* gave the invention to *Terpander*, and so does *Clemens Alexandrinus*. *Plutarch* says, 'no other proof need be urged of the excellence of *Terpander* in the art of playing upon the cithara than what is given by the register of the Pythic games, from which it appears that he gained four prizes successively at those solemnities. Of the works of this poet only a few fragments are now remaining.'

TERPSICHORE, in the mythology, one of the Nine Muses. She presided over dancing, of which she was reckoned the inventress. In painting she is drawn with a musical instrument in her hand, and crowned with laurel.—*Juv. vii. v. 35.*

TERRA (Lat. the earth), in the mythology, the wife of *Cælus* and mother of *Saturn* and *Ops*, or *Tellus*. See **OPS** and **TELLUS**.

TERRA DEL FUEGO, an island separated from the southern extremity of America, by a narrow sea called the Straits of Magellan; so called from the volcanoes observed on it. Of the south-west coast of *Terra del Fuego*, captain *Cook* says:—'With respect to inlets, islands, &c., it may be compared to the coast of Norway; for I doubt if there be an extent of three leagues where there is not an inlet or harbour which will receive and shelter the largest shipping. The

worst is that, till these inlets are better known, one has, as it were, to fish for anchorage. There are several lurking rocks on the coast; but happily none of them lie far from land, the approach to which may be known by sounding, supposing the weather so obscure that you cannot see it. For, to judge of the whole by the parts we have sounded, it is more than probable that there are soundings all along the coast, and for several leagues out to sea. Upon the whole, it is by no means the dangerous coast it has been represented. The currents between Cape Deseada and Cape Horn set from west to east, that is, in the same direction as the coast; but they are by no means considerable. To the east of the Cape their strength is much increased, and their direction is north-east to Staten Land. They are rapid in Strait le Maire and along the south coast of Staten Land, and set like a torrent round Cape St. John, where they take a north-west direction, and continue to run very strong both within and without New Year's Isle. While we lay at anchor within this island, I observed that the current was strongest during the flood; and that on the ebb its strength was so much impaired that the ship would sometimes ride head to the wind when it was at west and west-north-west. This is only to be understood of the place where the ship lay at anchor; for, at the very time we had a strong current setting to the westward, one of equal strength was found near the coast of Staten Land setting to the eastward; though probably this was an eddy current or tide.

The aspect of the country is dreary and uncomfortable, consisting of a chain of stupendous rocks, continually covered with snow. The inhabitants are said to be naturally as fair as Europeans, but go naked, and paint their bodies with the most gorgeous colors. Those on the south side are particularly barbarous; while those on the opposite side are simple and affable. The skins of wild animals are sometimes used to cover their bodies, upon occasions of extraordinary pomp; and their tents are made of poles, disposed in a conical form, covered with skins, or the bark or leaves of trees. Long. 51° 20' to 58° W., lat. 52° 30' to 55° 35' S.

TERRA FIRMA, an extensive tract of country in South America, which comprehends the three provinces of Darien, Veragua, and Panama or Terra Firma proper. Towards the east it is bounded by the province of Carthagena, the river St. Juan being the mutual boundary; on the west by the province of Costa Rica, in the kingdom of Guatamala; and on the north and south by the Atlantic and Pacific oceans. Its length from east to west is about 150 leagues, but if measured along the coast it is above 200. It is ninety leagues wide in the broadest part; and at the isthmus of Darien, where it is narrowest, its breadth is only eight leagues. It is watered by a variety of rivers.

TERRA JAPONICA, more commonly called catechu, a drug formerly supposed to be an extract from the seeds of the areca catechu, but lately discovered by Mr. Kerr, assistant surgeon to the civil hospital at Bengal, to be obtained from the mimosa catechu. Mr. Kerr gives the following account of the manner in which the extract is

made:—'After felling the trees the manufacturer carefully cuts off all the exterior white part of the wood. The interior colored wood is cut into chips, with which he fills a narrow-mouthed unglazed earthen pot, pouring water upon them until he sees it among the upper chips; when this is half evaporated, by boiling, the decoction, without straining, is poured into a flat earthen pot, and boiled to one-third part; this is set in a cool place for one day, and afterwards evaporated by the heat of the sun, stirring it several times in the day. When it is reduced to a considerable thickness it is spread upon a mat or cloth, which has previously been covered with the ashes of cowdung; this mass is divided into square or quadrangular pieces by a string, and completely dried by turning them frequently in the sun until they are fit for sale.' This extract is called cutt by the natives, by the English cutch, and by different authors terra japonica, catechu, khaath, cate, cachou, &c. 'In its pure state it is a dry pulverable substance, outwardly of a reddish color, internally of a shining dark brown, tinged with a reddish hue; in the mouth it discovers considerable astringency, succeeded by a sweetish mucilaginous taste.' According to Lewis 'it dissolves almost totally in water, excepting the impurities which are usually of the sandy kind, and amounting in the specimens I examined to about one-eighth of the mass. Of the pure matter, rectified spirit dissolves about seven-eighths into a deep red color; the part which it leaves undissolved is an almost insipid mucilaginous substance.' Catechu may be usefully employed for most purposes where an astringent is indicated, provided the most powerful be not required. But it is particularly useful in alvine fluxes; and, where these require the use of astringents, we are acquainted with no one equally beneficial. Besides this it is employed also in uterine profluvia, in laxity and debility of the viscera in general, in catarrhal affections, and various other diseases where astringents are necessary. It is often suffered to dissolve leisurely in the mouth, as a topical astringent for laxities and excoriation of the gums, for aphthous ulcers in the mouth, and similar affections. This extract is the basis of several fixed formulæ in our pharmacopœias, particularly of a tincture and an electuary; but one of the best forms under which it can be exhibited is that of a simple infusion in warm water, with a proportion of cinnamon or cassia; for it is thus at once freed from its impurities, and improved by the addition of the aromatic.

TERRA NUOVA, a considerable sea-port on the south coast of Sicily, in the Val di Noto, at the mouth of a river of this name. Among its public establishments are eight convents, an asylum, hospital, castle, and several well-built churches. Although the bay is somewhat exposed, there is good anchorage during the summer season, within a mile of the town, in eight or nine fathoms water. Terra Nuova is noted for its export of sulphur, dug up and manufactured in large quantities in the neighbourhood. Wine, corn, and fruits of various kinds, likewise form articles of export. Population 9000. Nineteen miles east of Licata, and fifty west of Syracuse.

TERRACE, *n. s.* } French *terrace*; Ital. *ter-*
TERRACED, *adj.* } *raccia*; of Lat. *terra*. A
small mount of earth covered with grass: the
adjective corresponding.

The reception of light into the body of the building must now be supplied, by *terracing* any story which is in danger of darkness.

Wotton's Architecture.

He made her gardens not only within the palaces, but upon *terrasses* raised with earth over the arched roofs, planted with all sorts of fruits. *Temple.*

Fear broke my slumbers: I no longer stay,
But mount the *terrace*, thence the town survey.

Dryden.

Clermont's *terraced* height and Esher's groves.

Thomson.

A **TERRACE** is a walk or bank of earth raised in a garden or court to a due elevation for a prospect. The name is also given to the roofs of houses that are flat, and whereon we may walk.

TERRACINA, an ancient city of Italy, in the pope's territory, in the Campagna of Rome, with a bishop's see. It was anciently called Anxur, and was the capital of Volsci. See **ANXUR** and **TERRACINA**. Its principal church was originally a temple of Jupiter, who was supposed to have a great partiality for the town, and is therefore styled Anxurus by Virgil. It is seated on the sea-coast, on the side of a mountain, forty-six miles south-east of Rome. Long. 13° 15' E., lat. 41° 24' N.

TERRÆ FILIUS, son of the earth, a student of the university of Oxford, formerly appointed in public acts to make satirical and jesting speeches against the members thereof, to tax them with any growing corruptions, &c.

TERRANTONA, a town of Spain in Arragon, eight miles south-east of Ainsa.

TERRAQUEOUS, *adj.* Lat. *terra* and *agua*. Composed of land and water.

The *terraqueous* globe is, to this day, nearly in the same condition that the universal deluge left it.

Woodward.

TERRAS, or **TRAAAS**, in mineralogy, a species of argillaceous earth. It differs but little in its principles from puzzolana, but is much more compact and hard, porous and spongy. It is generally of a whitish yellow color, and contains more heterogeneous particles, a spar, quartz, shoerl, &c., and something more of calcareous earth; it effervesces with acids, is magnetic, and fusible per se. When pulverised it serves as a cement, like puzzolana. It is found in Germany and Sweden. A species of red earth has been found in the parish of St. Elizabeth in Jamaica, which turns out to be an excellent substitute for terras or puzzolana earth, and may therefore be of great value to the inhabitants of the West Indies. One measure of this earth, mixed with two of well slaked lime and one of sand, form a cement that answers extremely well for building any dam or bridge, or any structure in water; for it will soon harden and become like a stone.

TERRASSON (Andrew), a French divine and priest of the oratory, born at Lyons, and much admired for his eloquence. His Sermons in 4 vols. 12mo. are esteemed. He died at Paris in 1723.

TERRASSON (Abbé John), brother of Andrew a French writer, born at Lyons in 1669. He distinguished himself in the dispute concerning Homer between La Motte and Madam Dacier, by writing a Dissertation contre l'Iliade. He wrote a political and moral romance called Sethos, full of learning and philosophy; and another capital work of his is a French translation of Diodorus Siculus. He died in 1750.

TERRASSON (Anthony), a relation of the two preceding, was born at Paris in 1705. He was eminent as an advocate, and wrote the History of Roman Jurisprudence, in folio, for which he was appointed censor royal, and a professor in the royal college. He also wrote Miscellanies of History, Literature, &c., 12mo. He died in 1782.

TERRÉ-BLUE, *n. s.* Fr. *terre* and *bleu*. A sort of earth.

Terre-blue is a light, loose, friable kind of lapis armenus. *Woodward on Fossils.*

TERRELLA, or little earth, is a magnet turned of a spherical figure, and placed so as that its poles, equators, &c., do exactly correspond with those of the world.

TERRENE, *adj.* Lat. *terrenus*. Earthly; terrestrial.

They think that the same rules of decency which serve for things done unto *terrene* powers, should universally decide what is fit in the service of God.

Hooker.

Our *terrene* moon is now eclipsed.

And it portends alone the fall of Antony.

Shakespeare.

God set before him a mortal and immortal life, a nature celestial and *terrene*; but God gave man to himself.

Raleigh.

Over many a tract
Of heaven they marched, and many a province wide,
Tenfold the length of this *terrene*.

Milton's Paradise Lost.

TERREOUS, *adj.* } Lat. *terreus*. Earthy; }
TERRESTRIAL, } consisting of earth: this }
TERRISTRIFY, *v. a.* } also terrestrial and ter- }
TERRESTRIOUS, *adj.* } restrius signify: ter- }
restrius is to reduce to an earthly state.

Far passing the height of men *terrestrial*,

Like an huge giant of the Titan race. *Spenser.*

Terrestrial heaven! danced round by other hea-
vens

That shine, yet bear their bright officious lamps,

Light above light. *Milton.*

There is but little similitude betwixt a *terreous*
humidity and plantal germinations.

Glanville's Scopsis.

According to the temper of the *terreous* parts at the bottom, variously begin intumescencies.

Broune's Vulgar Errors.

Though we should affirm, that heaven were but earth celestified, and earth but heaven *terrestriified*; or, that each part above had an influence on its divided affinity below; yet to single out these relations is a work to be effected by revelation. *Id.*

This variation proceedeth from *terrestrius* eminences of earth respecting the needle. *Broune.*

Thou broughtest Briareus with his hundred hands
So called in heaven; but mortal men below

By his *terrestrial* name Ægeon know. *Dryden.*

I did not confine these observations to land, or *terrestrial* parts of the globe, but extended them to the fluids. *Woodward.*

TERRÉ-PLEIN, or **TERRE-PLAIN**, in fortification, the top, platform, or horizontal surface of the

the rampart upon which the cannon are placed, and where the defenders perform their office. It is so called because it lies level, having only a little slope outwardly to counteract the recoil of the cannon. Its breadth is from twenty-four to thirty feet; being terminated by the parapet on the outer side, and inwardly by the inner talus.

TERRE-VERTE, *n. s.* Fr. *terre-verte*. A sort of earth.

Terre-verte owes its colour to a slight admixture of copper. *Woodward on Fossils.*

Terre-verte, or green earth, is light; it is a mean betwixt yellow-ochre and ultramarine.

Dryden's Dufresnoy.

TERRE-VERTE, in the color trade, green earth, is much used by painters, both singly for a good standing green, and in mixture with other colors. It is an indurated clay, of a deep bluish green color, and is found in the earth not in continued strata or beds, as most of the other earths are, but in large flat masses of different sizes imbedded in other strata; these break irregularly in the cutting, and the earth is generally brought out of the pit in lumps of different sizes. It is of a fine regular and even structure, and not very hard. It is of an even and glossy surface, very smooth to the touch, and in some degree resembling the morochthus or French chalk, but adhering firmly to the tongue. It does not stain the hands in touching it; but being drawn along a rough surface it leaves an even white line with a greenish cast. It does not ferment with acids, and it burns to a dusky brown color. It is dug in the island of Cyprus, and in many parts of France and Italy. That from the neighbourhood of Verona has been esteemed the best in the world; but of late there has been some dug in France that equals it. There is also an earth dug on Mendip Hills, in the sinking for coal, which, though wholly unobserved, is nearly, if not wholly, of equal value. When scraped, and the finer parts separated, it is ready to be made up with oil for the use of the painters, and makes the most true and lasting green of any body they use.

TERRIBLE, *adj.* } Fr. *terrible*; from
TERRIBLY, *adv.* } Lat. *terribilis*. Dread-
TERRIBLENESS, *n. s.* } ful; formidable; causing
fear: hence great, so as to overpower or offend: the adverb and noun substantive corresponding.

Having quite lost the way of nobleness, he strove to climb to the height of *terribleness*. *Sidney.*

Was this a face to be exposed
In the most *terrible* and nimble stroke
Of quick, cross lightning? *Shakespeare. King Lear.*

Being indisposed by the *terrible* coldness of the season, he reposed himself till the weather should mend. *Clarendon.*

Fit love for gods,
Not *terrible*, though *terroure* be in love. *Milton.*

I began to be in a *terrible* fear of him, and to look upon myself as a dead man. *Tillotson.*

The polished steel gleams *terribly* from far,
And every moment nearer shows the war. *Dryden.*

Thy native Latium was thy darling care,
Prudent in peace, and *terrible* in war. *Prior.*

Their *terribleness* is owing to the violent contusion and laceration of the parts. *Sharp's Surgery.*

The poor man squalled *terribly*. *Swift.*

TERRICOLIST (from *terra* and *colō*), one who cultivates or inhabits the earth.—*Ash.*

TERRIER, *n. s.* Fr. *terrier*; From Latin *terra*. A dog that follows his game underground.

The fox is earthed, but I shall send my two *terriers* in after him. *Dryden's Spanish Friar.*

King James's canons require that the bishops procure a *terrier* to be taken of such lands. *Ayliffe.*

TERRIER, in zoology. See **CANIS**.

TERRIFY, *v. a.* } Latin *terror* and *facio*.

TERRIFIC, *adj.* } To fright; shock with fear; to make afraid: the adjective corresponding.

Thou scarest me with dreams, and *terrifiest* me through visions. *Job vii. 14*

In nothing *terrified* by your adversaries.

Phil. i. 28.

Neither doth it besem this most wealthy state to be *terrified* from that which is right with any charges of war. *Knolles.*

The serpent, subtlest beast of all the field,
Of huge extent sometimes, with brazen eyes
And hairy mane *terrific*. *Milton's Paradise Lost.*

Though he was an offender against the laws, yet in regard they had treated him illegally, in scourging him and Silas uncondemned, against the privilege of Romans, he *terrifies* them with their illegal proceedings. *Kettlewell*

The British navy through ocean vast
Shall wave her double cross, t' extremest climes
Terrific. *Philip.*

The amazing difficulty of his account will rather *terrify* than inform him, and keep him from setting heartily about such a task as he despairs ever to go through with. *South.*

Meteors for various purposes to form;
The breeze to cheer; to *terrify*, the storm.

Blackmore.

TERRITORY, *n. s.* Fr. *territoire*; law Lat. *territorium*. Land; country; dominion; district.

Linger not in my *territories* longer than swiftest expedition will give thee time to leave our royal court. *Shakespeare.*

They erected a house within their own *territory*, half-way between their fort and the town.

Hayward.

Ne'er did the Turk invade our *territory*,
But fame and terror doubled still their files. *Denham.*

He saw wide *territory* spread
Before him, towns and rural works between.

Milton.

Ars and sciences took their rise, and flourished only in those small *territories* where the people were free. *Swift.*

TERROR, *n. s.* Lat. *terror*; Fr. *terreur*. Fear communicated or received.

They shot through both the walls of the town and the bulwark also, to the great *terror* of the defendants. *Knolles.*

It is the cowish *terror* of his spirit,
That dares not undertake. *Shakespeare. King Lear.*

O sight
Of *terror*, foul and ugly to behold,
Horrid to think, how horrible to feel! *Milton.*

So spake the griesly *terror*. *Id.*

Those enormous *terrors* of the Nile. *Prior.*

The pleasures of the land and *terroure* of the main.

Blackmore.

TERRORISTS, a name too justly given to that furious party of the French jacobins, who,

Juring the dictatorship of Robespierre, supported and applauded all his worst measures, while he murdered the greatest and best men of France, constantly calling out 'let terror be the order of the day,' and thus paved the path of blood that led to the establishment of the imperial despotism. See FRANCE.

TERSE, *adj.* Lat. *tersus*; Fr. *ters*. Smooth. Not in use.

Many stones precious and vulgar, although *terse* and smooth, have not this power attractive.

Brown's Vulgar Errors.

To raw numbers and unfinished verse,
Sweet sound is added now to make it *terse*. *Dryden.*
These accomplishments in the pulpit appear by a quaint, *terse*, florid style, rounded into periods without propriety or meaning. *Swift's Miscellanies.*

Various of numbers, new in every strain;
Diffused, yet *terse*, poetical, though plain. *Harte.*

TERTIAN, *n. s.* Lat. *tertiana*. Is an ague intermitting but one day, so that there are two fits in three days.

Tertians of a long continuance do most menace this symptom. *Harvey on Consumptions.*

TERTIAN FEVER. See MEDICINE.

TERTIUS, a prænomen very common among the Romans, who often distinguished their children by their numbers in the order of their birth, as Secundus, Tertius, Quartus, Quintus, Sextus, Septimus, Octavius, Decimus, &c.

TERTRE (John Baptist), a learned dominican, born at Calais in 1610. After having figured as a soldier, he entered into the monastic state, and became a zealous missionary in America, whence he returned in 1658. He wrote a General History of the French West India Islands, in 4 vols. 4to., and died at Paris in 1687.

TERTRE (Francis Joachim Duport Du), a learned French Jesuit, born at St. Malo in 1715. He wrote, 1. An Abridgment of the History of England, in 3 vols. 12mo. 2. An Abridgment of the History of Spain, in 5 vols. 12mo.; and other works. He died in 1759.

TERTULLIAN, or Quintus Septimus Florens Tertullianus, a celebrated priest of Carthage, was the son of a centurion in the militia, who served as a proconsul of Africa. He was educated in the Pagan religion; but being convinced of its errors, embraced Christianity, and became a zealous defender of the faith. He married, it is thought, after his baptism. Afterwards he took orders, and went to Rome: where, during the persecution under the emperor Severus, he published his Apology for the Christians; and, at the beginning of the third century, he embraced the sect of the Montanists. He lived to a very great age, and died in the reign of Caracalla, about the year 216. Many of his works are still extant. The best editions are those of Rigault; especially that of Venice in 1746, folio.

TERENCIUS, in antiquity, a very small brass coin, in use among the Romans. The inconvenience of such very small pieces being soon found, the teruncius became disused, but its name was still retained in reckoning, and thus it became a money of account. The teruncius at first was a quarter of the as or libra: hence, as the as contained twelve ounces, the teruncius

contained three, whence the name, which is formed of the Latin tres uncie. Teruncius was also used for the quarter of the denarius; so that when the denarius was at ten asses, the teruncius was worth two and a half: and, when the denarius was risen to sixteen, the teruncius was worth four. See DENARIUS.

TESCHEN, a town and circle of Austrian Silesia, comprehending the eastern part of that province, with an area of 740 square miles, and 152,000 inhabitants. It is very hilly on the south side, where the Carpathian chain commences, but the north is flat and marshy, so that throughout it is better adapted for grazing than tillage. The inhabitants are mostly of Slavonian origin.

TESCHEREMISSES, a nation of Tartars. See TARTARY.

TESHOO LOOMBOO, or Skiggatze Jeung, the seat of the Teshoo Lama, and the capital of all that part of Tibet immediately subject to his authority. Lat. 29° 4' N., long. 89° 7' E.

This place is properly a large stone monastery, consisting of 300 or 400 houses, the habitations of the gylongs, besides temples, mausoleums, and the palace of the sovereign pontiff. The buildings are none less than two stories high, flat roofed, and crowned with a parapet rising considerably above the roof, composed of heath and brushwood. The fortress of Shiggatze Jeung stands on a prominent ridge of rock, and commands the pass. From hence are roads to Bootan and Bengal, to Lahdack and Cashmere; to the mines of lead, copper, cinnabar, and gold; by Tingri Meidaun to Nepal; to Lassa and China. The distance to Catmandoo, the capital of Nepal, by the marching road, is estimated at 400 miles. In 1780 the journey of the deceased lama's attendants, from Pekin to Teshoo Loomboo, occupied seven months and eight days. On the north is situated the territory of Taranath Lama, bordering upon Russia and Siberia, and whose influence more especially extends over the Kilmuaks, or hordes of Calmuc Tartars.

The rock of Teshoo Loomboo is by far the loftiest in this neighbourhood. From the summit the eye commands a very extensive prospect, but no striking traces of population are to be discovered, the natives crowding into the hollow recesses. From the north side the celebrated river Brahmapootra, styled in the language of Tibet Erchoomboo, is visible. It here flows in a widely-extended bed through many channels, forming a multitude of islands. Its principal channel is described as being narrow, deep, and never fordable. In 1783 there were reckoned on the establishment of the monastery at Teshoo Loomboo no less than 3700 gylongs for the performance of daily prayer in the goomba or temple. Four lamas, chosen from among them, superintend and direct their religious ceremonies. Their stated periods of devotion are the rising of the sun, moon, and sunset. Youth, intended for the service of the monastery, are received into it at the age of eight or ten years. On admission they are enjoined sobriety, forego the society of women, and confine themselves to the austere practices of the cloister. There are also a considerable number of nunneries, the regulations of which are equally strict. And at this

place there is an extensive establishment, under the direction of the monastery, for the manufacture of images, in which they excel the Chinese.

The annual consumption of tea in the territory of Teshoo Loomboo amounts to the value of £70,000. At the capital 300 Hindoos, Gosains, and Sunyasses, are daily fed by the bounty of the lama. The whole system exhibits a hierarchy of long duration, great opulence, and many practical benefits to the people. The gylongs, or monks, having devoted themselves to the duties of religion, obtain a large portion of respect from their countrymen, who follow worldly avocations. Being attached by a common bond of union, the one portion to labor, and the other to pray, they enjoy in peace and harmony the bounties of nature; and find it unnecessary to employ a single man in arms, either to defend their territory, or maintain their rights.

TESSELLATED, *adj.* Lat. *tessella*. Variegated by squares.

Van Helmont produced a stone very different from the tessellated pyrites. *Woodward on Fossils.*

TESSELLATED PAVEMENTS, those of rich Mosaic work made of curious square marbles, bricks, or tiles, called tessellæ from their resembling dice.

TESSERA, in Roman antiquity, denoted in its primary sense a cube or dye; so called from the Greek word *τεσσαρα* or *τεσσαρα*, four; respect being had to its number of sides, distinct from the two horizontal planes above and below. And it was thus distinguished from the talus, which, being round at each end, contained only four planes or faces on which it could stand; and therefore when thrown had no more than two side faces in view. Hence ludere talis et ludere tesseris are spoken of by Roman writers as two different games. The syllable tes occurs often in Roman inscriptions. The word tessera was applied to many other things, not so much from a similitude in the figure, as from the relation they bore to some other thing of which they were the sign or token; as the points on the upper plane of the dye denoted the good or ill success of the cast. 1. *T. frumentaria* was a small tally given by the emperors to the populace at Rome, entitling them to the reception of a quantity of corn from the public at stated seasons. The person who had the inspection of these was called tesserarius. They were made of wood and of stone. There was another kind of tessera which entitled persons to a sight of the public games and other diversions, usually made in the form of an oblong square.

2. *T. hospitalis* was either public or private. As to the former, we find, among the inscriptions published by Gruter, instances of two municipal towns which put themselves under the patronage of the Roman governor; and the reciprocal engagement between them, engraved on two copper plates, in the form of an oblong square, with a pediment at the top, is called in both tessera hospitalis. The design of it was to cultivate or maintain a lasting friendship between private persons and their families; and gave a mutual claim to the contracting parties and their descendants of a reception and kind treatment at each other's houses, as occasion offered.

For which end those tesserae were so contrived as best to preserve the memory of that transaction to posterity; and one method of doing this was by dividing one of them lengthwise into two equal parts; upon each of which one of the parties wrote his name, and interchanged it with the other. From this custom came the prevailing expression tesseram hospitalem confringere, applied to persons who violated their engagements.

3. *T. militaris* was a signal given by the general, or chief commander of an army, as a direction to the soldiers for executing any duty or service required of them. This, upon urgent occasions, was only vocal; but, in ordinary cases, it was written on a tablet, commonly made of wood. Besides these civil and military tesserae, there are others which relate to religious affairs, and may be called sacred.

TEST, *n. s.* } Fr. *test*; Ital. *testa*. The **TESTED**, *adj.* } cupel by which refiners try their metals; trial; examination; any means of trial; judgment; distinction: tested is tried by a test.

Let there be some more test made of my metal, Before so noble and so great a figure Be stamp't upon it.

Shakspeare. Measure for Measure.

Not with fond shekels of the tested gold.

Shakspeare.

Whom should my muse then fly to, but the best Of kings for grace; of poets, for my test?

Ben Jonson.

They who thought worst of the Scots, did not think there would be no fruit or discovery from that test.

Clarendon.

What use of oaths, of promise, or of test, Where men regard no god but interest?

Waller.

To be read herself she need not fear: Each test, and every light, her muse will bear.

Dryden.

Our penal laws no sons of yours admit, Our test excludes your tribe from benefit.

Id.

Thy virtue, prince, has stood the test of fortune Like purest gold, that, tortured in the furnace, Comes out more bright, and brings forth all its weight.

Addison.

Unerring Nature, still divinely bright, One clear, unchanged, and universal light, Life, force and beauty, must to all impart, At once the source, and end, and test of art.

Pope.

The **TEST** is a vessel used in metallurgy for absorbing the scoria of metallic bodies when melted. See **CUPEL**. Some of the German writers recommended, both for tests and cupels, a sort of friable opaque stone, called white spath, which appears to be a species of gypsum, or of the stones from which plaster of Paris is prepared. The spath is directed to be calcined with a gentle fire, in a covered vessel, till the slight crackling which happens at first has ceased, and the stone has fallen in part into powder: the whole is then reduced into subtle powder, which is passed through a fine sieve, and moistened with so much of a weak solution of green vitriol as is sufficient for making it hold together. Gellert, however, finds, that if the stone is of the proper kind, which can be known only by trials, calcination is not necessary. Scheffer observes, that these kinds of tests are liable to soften or fall asunder in the fire, and that this inconvenience may be remedied by the mixing with the

uncalcined stone somewhat less than equal its weight, as eight-ninths of such as has been already used and is penetrated by the scoria of the lead, taking only that part of the old test which appears of a green gray color, and rejecting the red crust on the top. Tests or cupels made of the spath are said not to require so much caution in nealing and heating them as the common ones; it appears, however, from Scheffer's account, that they are less durable than those made of the ashes of bones, though greatly superior to those of wood-ashes. Vegetable ashes, which stand pretty well the testing of silver, can scarcely bear any great quantity of gold, this metal requiring a considerably stronger fire than the other; but bone-ashes answer so effectually, and are among us so easily procurable, that it is not needful for the refiner to search for any other materials; though those who work off large quantities of lead, in order to gain a little silver or gold contained in it, may possibly, in places remote from populous cities, avail themselves of substances similar to the spath above-mentioned. The test, for its greater security, is fixed in the mould in which it was formed; which is sometimes a shallow vessel made of crucible earth or cast-iron, more commonly an iron-hoop, with three bars arched downwards across the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or more, according to the quantity of metal to be tested at once. The ashes or earthy powder, moistened as for making cupels, are pressed down in the mould so as to completely fill it or rise a little above the sides; with care to make the mass equally solid, and to put in at once, or at least after the bottom has been pressed close, as much of the matter as will be sufficient for the whole; for any additional quantity will not unite thoroughly with the test, but be apt to part from it in the fire. The edges are pared smooth, and a portion cut out from the middle with a bent knife, so as to leave a proper cavity, which is smoothed by strewing some dry powder on the surface, and rolling on it a wooden, or rather a glass ball. The process of testing is often performed in the same manner as that of cupellation; but, where great quantities of base metal are to be worked off from a little gold, recourse is had to a more expeditious method, that of testing before the bellows. An oval test is placed in a cavity, made in a hearth of a convenient height, and some moistened sand or ashes pressed round it to keep it steady; the nose of a bellows is directed along its surface, in such a manner, that if ashes are sprinkled in the cavity of the test, the bellows may blow them completely out; some have an iron plate fixed before the bellows, to direct the blast downwards. To keep the surface of the test from being injured in putting in the metal, some cloths or pieces of paper are interposed. The fuel consists of billets of barked oak laid on the sides of the test, with others laid crosswise on these; the bellows impel the flame on the metal, clear the surface of ashes or sparks of coal, hasten the scorification of the lead, and blow off the scoria, as fast as it forms, to one end of the test, where it runs out through a notch made for that purpose. About

two-thirds of the scorified lead may be thus collected; the rest being partly absorbed by the test, and partly dissipated by the action of the bellows. Care must be taken not to urge the blast too strongly, lest some portion of the gold should be carried away by the fumes impetuously forced off from the lead, and some minute particles of it entangled and blown off with the scoriæ.

TEST ACT, in law, was the statute. 25 Car. II. cap. 2, which directs all officers, civil and military, to take the oaths, and make the declaration against transubstantiation, in the court of king's bench or chancery, the next term, or at the next quarter-sessions, or (by subsequent statutes) within six months after their admission; and also within the same time to receive the sacrament of the Lord's Supper, according to the usage of the church of England, in some public church, immediately after divine service or sermon, and to deliver into court a certificate thereof, signed by the minister and churchwarden, and also to prove the same by two credible witnesses, upon forfeiture of £500, and disability to hold the said office. It has been the honor of the ministry of the duke of Wellington to procure the repeal of this most objectionable and absurd law.

TESTACEA, in the Linnæan system of zoology, the third order of vermes. This order comprehends all the shell-fish arranged by Linnæus under thirty-six genera. Shell-fish are animals with a soft body, covered by or enclosed in a firm, hard, and as it were, stony habitation, composed, according to their three separate orders, 1st, Of many parts which are arranged under the name of multivalve; 2d, Of two parts which are called bivalves; 3d, Of one part or piece only, which we call univalves. Those parts, pieces, or valves, are more or less moveable at the animal's pleasure. See CONCHOLOGY.

TESTACEOUS, *adj.* Fr. *testacé*; Lat. *testaceus*. Consisting of shells; composed of shells; having continuous, not jointed shells; opposed to crustaceous.

Testaceous, with naturalists, is a term given only to such fish whose strong and thick shells are entire, and of a piece; because those which are joined, as the lobsters, are crustaceous: but, in medicine, all preparations of shells and substances of the like kind are thus called. *Quincy.*

Several shells were found upon the shores, of the crustaceous and *testaceous* kind.

Woodward's Natural History.

TESTACEOUS, in medicine, all preparations of shells, and such like substances, are called testaceous. Such are powders of crabs' claws and eyes, pearls, &c. Dr. Quincy and others suppose the virtue of all testaceous medicines to be alike; that they seldom or never enter the lacteals, but that the chief of their action is in the first passages; in which, however, they are of great use in absorbing acidities. Hence they become of use in fevers, and especially in rectifying the many distempers in children which generally owe their origin to such acidities.

TESTACEOUS, in zoology, is synonymous with testacea.

The vast mountains of calcareous earth which

occur in different parts of the world, owe their origin, in general, it is supposed, to the destruction of marine testaceous animals, which in long process of time formed these extensive and accumulated heaps; Fourcroy, in his Chemical Elements, has given a beautiful account of this process of nature, to which we refer.—See Dr. John Thomson's edition, part iii. chap. 7, sect. 1.

According to our navigators, there are in the Southern Ocean perpendicular coralline rocks, formed entirely of sea-shells, which are of such magnitude as to render the navigation of those seas extremely dangerous. The shells of some of the testaceous animals in the South Sea are of a vast size. The kemo shell on the coast of Sumatra is frequently found three or four feet in diameter, and as white as ivory. See Marsden's History of the Island of Sumatra, page 10.

It may be remarked that, while testaceous shells are formed with carbonate of lime, the shells of crustaceous animals and the shells of bird's eggs contain also a portion of phosphate of lime. Its use in the former is not known; but the design of nature in furnishing the shells of eggs with phosphoric acid is very apparent. The body of the egg contains neither phosphoric acid nor lime; it was necessary, therefore, that nature should provide means of furnishing both these substances, which it does at the expense of the shell; which becomes thinner and thinner during the whole time of incubation, till the living embryo hath appropriated a sufficient quantity for the formation of its bones. Part of the albumen combines with the shell for this purpose, and another portion forms feathers.

One thousand parts of egg-shells are composed of—

Carbonate of lime	396
Phosphate of lime	57
Gluten and moisture	47
	1000

If fowls are kept in a state of confinement, where they cannot get at any calcareous earth, they lay their eggs without shells.

TESTAMENT, n. s. } Fr. *testament*; Lat
TESTAMENTARY, adj. } *testamentum*. A will; any writing directing the disposal of the possessions of a man deceased: given by, or contained in, a will.

He bringeth arguments from the love which always the testator bore him, imagining that these, or the like proofs, will convict a *testament* to have that in it which other men can no where by reading find.

Hooker.

All the temporal lands, which men devout
 By *testament* have given to the church,
 Would they strip from us. *Shakspeare. Henry V.*

How many *testamentary* charities have been defeated by the negligence or fraud of executors; by the suppression of a will: the subornation of witnesses, or the corrupt sentence of a judge!

Aterbury.

He ordained by his last *testament*, that his *Ancid*
 should be burnt. *Il.*

TESTAMENT, or LAST WILL, according to the old Roman lawyers, is, *voluntatis nostræ justa sententia, de eo quod quis post mortem suam fieri velit*; which may be thus rendered in Eng-

lish, 'the legal declaration of a man's intentions, which he wills to be performed after his death.' It is called *sententia*, to denote the circumspection and prudence with which it is supposed to be made; it is *voluntatis nostræ sententia*, because its efficacy depends on its declaring the testator's intention, whence in English it is emphatically styled his will; it is *justa sententia*; that is, drawn, attested, and published, with all due solemnities and forms of law: it is *de eo quod quis post mortem suam fieri velit*, because a testament is of no force till after the death of the testator. These testaments are divided into two sorts; written, and verbal or nuncupative, being declared by the testator in extremis, before a sufficient number of witnesses, and afterwards reduced to writing. But as nuncupative wills and codicils (which were formerly more in use than at present when the art of writing is become more general) are liable to great impositions, and may occasion many perjuries, the statute of frauds, 29 Car. II. c. 3, enacts, 1. That no written will shall be revoked or altered by a subsequent nuncupative one, except the same be in the lifetime of the testator reduced to writing, and read over to him, and approved; and unless the same be proved to have been so done by the oaths of three witnesses at the least, who, by statute 4 and 5 Anne, c. 16, must be such as are admissible upon trials at common law. 2. That no nuncupative will shall in anywise be good, where the estate bequeathed exceeds £30 unless proved by three such witnesses, present at the making thereof (the Roman law requiring seven), and unless they, or some of them, were specially required to bear witness thereto by the testator himself; and unless it was made in his last sickness, in his own habitation or dwelling-house, or where he had been previously resident ten days at the least, except he be surprised with sickness on a journey, or from home, and dies without returning to his dwelling. 3. That no nuncupative shall be proved by the witnesses after six months from the making, unless it were put in writing within six days. Nor shall it be proved till fourteen days after the death of the testator, nor till process has first issued to call in the widow, or next of kin, to contest it if they think proper. As to written wills, they need not any witness of their publication. We speak not here of devises of lands, which are entirely another thing, a conveyance by statute, unknown to the feudal or common law, and not under the same jurisdiction as personal estates. But a testament of chattels, written in the testator's own hand, though it has neither his name nor seal to it, nor witnesses present at its publication, is good; provided sufficient proof can be had that it is his hand-writing; and, though written in another man's hand, and never signed by the testator, yet if proved to be according to his instructions, and approved by him, it hath been held a good testament of the personal estate. No testament is of any effect till after the death of the testator; *Nam Omne testamentum morte consummatum est, et volunta testatoris est ambulatoria usque ad mortem*. And therefore, if there be many testaments, the last will overthrows all the former; but the republication of a former will revokes

one of a later date and establishes the first again. Regularly, every person hath full power and liberty to make a will that is not under some special prohibition by law or custom; which prohibitions are principally upon three accounts; for want of sufficient discretion; for want of sufficient liberty and free-will; and on account of criminal conduct. 1. In the first species are to be reckoned infants, under the age of fourteen if males, and twelve if females; which is the rule of the civil law. Madmen, or otherwise non compotes, idiots or natural fools, persons grown childish by reason of old age or distemper, such as have their senses besotted with drunkenness. 2. Such persons as are intestate for want of liberty or freedom of will, by the civil law, are of various kinds; as prisoners, captives, and the like. But the law of England does not make such persons absolutely intestate; but only leaves it to the discretion of the court to judge, upon the consideration of their particular circumstances of duress, whether or no such persons could be supposed to have liberum animi testandi. A married woman is not only utterly incapable of devising lands, being excepted out of the statute of wills, 34 and 35 Hen. VIII. c. 5, but also she is incapable of making a testament of chattels, without the licence of her husband. The queen-sort is an exception to this general rule; for she may dispose of her chattels by will, without the consent of her lord; and any feme-covert may make her will of goods which are in her possession in auter droit, as executrix or administratrix; for these can never be the property of her husband; and if she has any pin-money, or separate maintenance, it is said she may dispose of her savings thereof by testament, without the control of her husband. But if a feme-sole make her will, and afterwards marries, such subsequent marriage is esteemed a revocation in law, and entirely vacates the will. 3. Persons incapable of making testaments on account of their criminal conduct are, in the first place, all traitors and felons, from the time of conviction; for then their goods and chattels are no longer at their own disposal, but forfeited to the king. Neither can a felo de se make a will of goods and chattels, for they are forfeited by the act and manner of his death; but he may make a devise of his lands, for they are not subject to any forfeiture. Outlaws also, though it be but for debt, are incapable of making a will so long as the outlawry subsists; for their goods and chattels are forfeited during that time. As for persons guilty of other crimes, short of felony, who are by the civil law precluded from making testaments (as usurers, libellers, and others of a worse stamp), at the common law their testaments may be good. And, in general, the rule is, and has been so at least ever since Glanvil's time, quod libera sit eujusque ultima voluntas. Testaments may be avoided three ways: 1. If made by a person laboring under any of the incapacities before-mentioned; 2. By making another testament of a later date; and, 3. By cancelling or revoking it. For though I make a last will and testament irrevocable in the strongest words, yet I am at liberty to revoke it.

TESTATE, *adj.* } Lat. *testatus*. Having
TESTATOR, *n. s.* } made a will: he or she who
TESTATRIX. } makes a will.
He bringeth arguments from the love or goodwill which always the *testator* bore him. *Hooker*.
The same is the case of a *testator* giving a legacy by kindness, or by promise and common right. *Taylor*.

By the canon law, the bishop had the lawful distribution of the goods of persons dying *testate* and intestate. *Ayliffe*.

TESTER, *n. s.* Fr. *teste*, a head; this coin probably being distinguished by the head stamped upon it. A sixpence; the cover of a bed.

Come manage me your cavalier: hold, there is a *tester* for thee. *Shakspeare. Henry IV.*

A crown goes for sixty pence, a shilling for twelve pence, and a *tester* for six pence. *Locke*.

Those who bore bulwarks on their backs,
And guarded nations from attacks,
Now practise every pliant gesture,
Op'ning their trunk for every *tester*. *Swift's Miscellany*.

Young man, your days can ne'er be long,
In flower of age you perish for a song:
Plums and directors, Shylock and his wife,
Will elub their *testers* now to take thy life. *Pope*.

TESTER, TESTON, the name of a coin struck in France by Louis XII., in 1513, and in Scotland in the time of Francis II., and Mary queen of Scotland, so called from the head of the king, which was engraved upon it. The silver it contained was eleven deniers eighteen grains, its weight seven deniers $11\frac{1}{2}$ grains, and its value ten sols. The coinage of it was prohibited by Henry III. in 1575, when the value of it was augmented to fourteen sols six deniers. The *teston* or *tester* among us was rated at 12*d.* in the reign of Henry VIII., and afterwards reduced to 6*d.*

TESTES, in anatomy, the testicles. See TESTICLE, and ANATOMY.

TESTICLE, *n. s.* Lat. *testiculus*. Stone.

That a beaver, to escape the hunter, bites off his *testicles* or stones, is a tenet very ancient.

Browne's Vulgar Errors.

The more certain sign from the pains reaching to the groins and *testicles*. *Wiscman's Surgery*.

TESTIFY, *v. n.* & *v. a.* } Lat. *testificor*. To

TESTIFICATION, *n. s.* } witness; prove; give evidence: give evidence on a point: the noun substantive corresponding.

One witness shall not *testify* against any, to cause him to die. *Numb. xxxv. 30.*

Jesus needed not that any should *testify* of man; for he knew what was in man. *John ii. 25.*

We speak that we do know, and *testify* that we have seen; and ye receive not our witness. *Id. iii. 11.*

When together we have all received those heavenly mysteries wherein Christ imparteth himself unto us, and giveth visible *testification* of our blessed communion with him, we should, in hatred of all heresies, factions, and schisms, declare openly ourselves united. *Hooker*.

The event was dire,

As this place *testifies*. *Milton's Paradise Lost*.

She appeals to their closets, to their books of devotion, to *testify* what care she has taken to establish her children in a life of solid piety and devotion.

Law

In places solemnly dedicated for that purpose, is a more direct service and *testification* of our homage to God.

South.

TESTIMONY, *n. s. & v. a.* Lat. *testimonium*. Evidence given; proof by witness; public or open attestation: to witness.

The proof of every thing must be by the *testimony* of such as the parties produce.

Spenser.

If I bring you sufficient *testimony*, my ten thousand ducats are mine.

Shakspeare. Cymbeline.

Let him be but *testimonied* in his own bringings forth, and he shall appear a scholar, a statesman, and a soldier.

Shakspeare.

To quote a modern Dutchman, where I may use a classic author, is as if I were to justify my reputation, and neglect all persons of note and quality that know me, and bring the *testimonial* of the scullion in the kitchen.

Selden.

We maintain the uniform *testimony* and tradition of the primitive church.

White.

Evidence is said to arise from *testimony*, when we depend upon the credit and relation of others for the truth or falsehood of any thing.

Wilkins.

By his prescription a sanctuary is framed, An ark; and in the ark his *testimony*;

The records of his covenant.

Milton.

Thou for the *testimony* of truth hast born Universal reproach.

Id.

I could not answer it to the world, if I gave not your lordship my *testimony* of being the best husband.

Dryden.

It is possible to have such *testimonials* of divine authority as may be sufficient to convince the more reasonable part of mankind, and pray what is wanting in the testimonials of Jesus Christ?

Burnet's *Theory of the Earth*.

A clerk does not exhibit to the bishop letters missive or *testimonial*, testifying his good behaviour.

Ayliffe.

Hospitable people entertain all the idle vagrant reports, and send them out with passports and *testimonials*, and will have them pass for legitimate.

Government of the Tongue.

TESTUDO, the tortoise, in zoology, a genus belonging to the class of amphibia, and order of reptilia. The body has a tail, and is defended with a bony or coriaceous covering. The mouth has naked mandibles without teeth. There are thirty-three species, of which

TESTUDO MIDAS, the common sea turtle, is the most remarkable. It is found in the island of Ascension and other places in the South Sea. The shell is so very strong that it can carry more than 600 lbs. on its back, or as many men as can stand on it loaded. It digs round holes in the sand, in which it lays a vast number of eggs yearly, to the amount of 1000, it is said. It broods on them during the night. Its flesh is of a greenish color, makes excellent food, and is the favorite dish of sailors as well as of epicures. It lives on cuttle and shell fish, and grows to a prodigious size, some having been found to weigh 480 lbs. The Americans find so good account in catching turtle, that they have made themselves very expert at it; they watch them from their nests on shore, in moon-light nights; and, before they reach the sea, turn them on their backs, and leave them till morning; when they are sure to find them, since they are utterly unable to recover their former posture; at other times they hunt them in boats, with a peculiar kind of spear, striking them with it through the

shell; and, as there is a cord fastened to the spear they are taken much in the same manner as the whales.

TESTUDO, in antiquity, was particularly used among the poets, &c., for the ancient lyre; because it was originally made by its inventor Mercury, of the back or hollow of the testudo aquatica, or sea tortoise, which he accidentally found on the banks of the river Nile. See LYRE.

TESTUDO, in the military art of the ancients, was a kind of cover or screen which the soldiers, e. g. a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other.

TESTUDO was also a kind of large wooden tower which moved on several wheels, and was covered with bullock hides, serving to shelter the soldiers when they approached the walls to mine them, or batter them with rams. It was called testudo, from the strength of its roof, which covered the workmen as the shell does the tortoise.

TESTY, *adj.* } Fr. *testie*; Ital. *testurdo*.

TESTINESS, *n. s.* } Fretful; peevish: the noun substantive corresponding.

Must I stand and crouch under your *testy* humour?

Shakspeare.

King Pyrrhus cured his splenetic And *testy* courtiers with a kick.

Hudibras

Testiness is a disposition or aptness to be angry.

Loeke.

In all thy humours, whether grave or mellow, Thou'rt such a touchy, *testy*, pleasing fellow; Hast so much wit, and mirth, and spleen about thee, There is no living with thee, nor without thee.

Addison.

TETANUS, a dreadful spasmodic disorder, in which the whole body becomes rigid and inflexible. It most commonly proves mortal. See MEDICINE.

TETBURY, a market-town in the county of Gloucester, and on the verge of the county of Wilts. It once boasted of a good trade in the woollen manufactory, which has of late years declined materially; indeed the place is rendered uncommonly dull, in consequence of the desertion of trade. The town is much esteemed for the salubrity of its air, and richness of its soil; the streets are capacious and clean, and the houses principally built of small stone, covered with mortar. The church, which was rebuilt in 1781, is a rich and beautiful specimen of modern Gothic architecture. There is a spacious market-house and a convenient town hall. The Bristol Avon river takes its rise in this parish, which it leaves immediately, and passing by Brokenborough, Malmesbury, Chippenham, Bradford, and Bath, (where it becomes navigable), runs to Bristol, and thence on to the spacious bosom of the channel. The town is governed by the feoffees and a bailiff, who is chosen annually. Market day is Wednesday. Fairs Ash Wednesday, and 22d of July, for cattle, sheep, and horses; Wednesday before old Lady day, Wednesday before old Michaelmas, and Wednesday after, for hiring servants. Population 2734.

TETCHY, *adj.* Ital. *testaccio*. Froward; peevish: or a corruption of testy or touchy, perhaps.

A grievous burthen was thy birth to me,
Tetchy and wayward was thy infancy.

Shakspeare. Richard III.

A silly schoolboy, coming to say my lesson to the world, that peevish and tetchy master.

Graunt.

TETE A TETE, *n. s.* Fr. *tête à tête*. Cheek by jowl.

Long before the squire and dame
Are *tête à tête*.

Prior.

Deluded mortals, whom the great
Chuse for companions *tête à tête*;
Who at their dinners, en famille,
Get leave to sit whene'er you will.

Swift's Miscellanies.

TETHER, *n. s.* See TEDDER. A string by which horses are held from pasturing too wide.

Hamlet is young,
And with a larger tether he may walk
Than may be given you.

Shakspeare.

Fame and censure with a tether,
By fate, are always linked together.

Swift's Miscellanies.

Imagination has no limits; but where it is confined we find the shortness of our tethers.

Swift.

TETHYS, in the mythology, the greatest of all the sea goddesses, the daughter of Coelus or Uranus, and Terra, and the wife of Oceanus, and mother of the river gods, the sea nymphs, &c.

TETHYS, in entomology, a genus of insects belonging to the class of vermes, and order of mollusca. The body is oblong, fleshy, and without feet; the mouth consists of a cylindrical proboscis under the duplicature of a lip; and there are two foramina at the left side of the neck. The species are two, both inhabitants of the ocean.

TETRACERA, in botany, a genus of plants belonging to the class of polyandria, and order of tetragynia, and in the natural system ranging under the doubtful. The calyx is hexaphyllous, and the capsules four. There is only one species, viz. *T. volubilis*.

TETRADYNAMIA (*τεσσαρες*, four, and *δυναμις*, power), four powers; the fifteenth class of Linnæus's sexual system, consisting of plants with hermaphrodite flowers having six stamina, four of which are long, and two short; it corresponds to the siliquose of Ray, and cruciformes of Tournefort. All the species are distinguished by cruciform flowers. It comprehends two orders, gymnospermia, those plants which have naked seeds, being four in number; (except phryma which is monospermous); and angiospermia, which contains those plants the seeds of which are enclosed in a capsule. See BOTANY, Index.

TETRAEDRON, or TETRAHEDRON, in geometry, is one of the five platonic or regular bodies or solids, comprehended under four equilateral and equal triangles. Or it is a triangular pyramid of four equal and equilateral faces.

TETRAGON, in astrology, denotes an aspect of two planets with regard to the earth, when they are distant from each other a fourth part of a circle, or 90°. The tetragon is expressed by the character □, and is otherwise called a square or quartile aspect.

TETRAGON, in geometry, a quadrangle, or a figure having four angles. Such as a square, a

parallelogram, a rhombus, and a trapezium. It sometimes also means peculiarly a square.

TETRAGONAL, *adj.* Gr. *τετραγωνος*. Four square.

From the beginning of the disease, reckoning on unto the seventh day, the moon will be in a tetragonal or quadrate aspect, that is, four sigus removed from that wherein the disease began; in the fourteenth day it will be in an opposite aspect, and at the end of the third septenary tetragonal again.

Browne's Vulgar Errors.

TETRAGONIA, in botany, a genus of plants belonging to the class of icosandria, and order of monogynia; and in the natural system ranging under the thirteenth order, succulentæ. The calyx is divided into three, four, or five parts. There is no corolla; the drupæ is beneath, and the nut three or eight-celled. There are seven species; the puticosa, decumbens, herbacea, echinata, expansa, crystallina, and japonica.

TETRAGRAMMATON (*τετραγραμματον*, a denomination given by the Greeks to the Hebrew name of God יהוה, Jehova, because in the Hebrew it consists of four letters.

TETRAGYNIA, (*τεσσαρες*, four, and *γυνη*, a woman), the name of an order in the fourth, fifth, sixth, eighth, and thirteenth classes in the sexual system; consisting of plants which, to the classic character, whatever it is, add the circumstance of having four styles or female organs. Herb paris and grass of Parnassus furnish examples. See BOTANY.

TETRANDRIA (*τεσσαρες*, four, and *ανηρ*, a man or husband), the name of the fourth class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers, which have four stamina or male organs that are of equal length. In this last circumstance consists the main difference, according to Linnæus, between the plants of the class in question and those of the fourteenth class didynamia, in which the four stamina are of unequal length, two of them being long, and two short. The orders of this numerous class are three, founded upon the number of styles or female organs. Scabious, teazel, barren wort, the stary plants of Ray, and the greater number of genera in this class, have one style; dodder and hyecoum have two; holly and a few others have four.

TETRAO, in ornithology, a genus of birds belonging to the order of gallinæ, and thus characterised by Linnæus: there is a spot near the eyes naked or papillose, or covered, though more rarely with feathers. Gmelin has enumerated about sixty-six species. The genus tetrao comprehended both the grouse partridge and quail; but Dr. Latham, with great judgment and propriety, has made two genera of them, under the names of tetrao, comprehending the grouse; and perdx, comprehending the partridge and quail. See PERDX. Dr. Latham thus distinguishes the genus tetrao: the bill is like a crooked cone, with a naked scarlet skin above each eye, and the feet feathered to the toes. He reckons twenty species. The four following are found in Britain:—

1. *T. lagopus*, the white game, or ptarmigan, is fifteen inches in length, and weighs nineteen ounces. Its plumage is of a pale brown or ash

color, elegantly crossed or mottled with small dusky spots and minute bars; the head and neck with broad bars of black, rust color, and white: the belly and wings are white, but the shafts of the greater quill-feathers black. In the male the gray color predominates, except on the head and neck, where there is a great mixture of red, with bars of white. The females and young birds have a great deal of rust color in them. The tail consists of sixteen feathers; the two middle of which are ash colored, mottled with black, and tipped with white; the two next black, slightly marked with white at their ends, the rest wholly black; the feathers incumbent on the tail are white, and almost entirely cover it. Ptarmigans are found in these kingdoms only on the summits of the highest hills of the Highlands of Scotland, of the Hebrides, and Orkneys; and a few still inhabit the lofty hills near Keswick in Cumberland, as well as the mountains of Wales. They live amidst the rocks, perching on the gray stones, the general color of the strata in those exalted situations. They are very silly birds; so tame as to bear driving like poultry; and, if provoked to rise, take very short flights, making a great circuit like pigeons. Like the grouse, they keep in small packs; but never, like those birds, take shelter in the heath, but beneath loose stones. To the taste they scarcely differ from a grouse. These birds are called by Pliny lagopi, their feet being clothed with feathers to the claws, as the hare's are with fur: the nails are long, broad, and hollow. The first circumstance guards them from the rigor of the winter; the latter enables them to form a lodge among the snow, where they lie in heaps to protect themselves from the cold. The feet of the grouse are clothed in the same manner; but those of the last two species here described, which perch upon trees, are naked, the legs only, being feathered, not being in want of such a protection.

2. *T. Scoticus*, the red game, or moor-fowl, is peculiar to the British islands. The male weighs about nineteen ounces; and is in length fifteen inches and a half. The bill is black: the irides hazel colored. The throat is red. The plumage on the head and neck is of a light tawny red; each feather is marked with several transverse bars of black. The back and scapular feathers are of a deeper red; and on the middle of each feather is a large black spot; the breast and belly are of a dull purplish brown, crossed with numerous narrow dusky lines; the quill-feathers are dusky; the tail consists of sixteen feathers of an equal length, all of them (except the four middlemost) are black, and the middle feathers are barred with red; the thighs are of a pale red, barred obscurely with black; the legs and feet clothed to the very claws with thick soft white feathers. The claws are whitish, very broad and strong. The female weighs only fifteen ounces. The colors in general are duller than those of the male; the breast and belly are spotted with white; and the tips of some of the coverts of the wings are of the same color. These birds pair in the spring, and lay from six to ten eggs. The young brood follow the hen the whole summer; in the winter they join in flocks of forty or fifty, and become remarkably shy and wild;

they always keep on the tops of the hills, are scarcely ever found on the sides, and never descend into the valleys. Their food is the mountain berries and the tops of the heaths. See SHOOTING.

3. *T. tetrax*, black grouse, or black cock, like the woodcock, is fond of woody and mountainous situations; feeding on bilberries and other mountain fruits, and in the winter on the tops of the heath. In the summer they frequently descend from the hills to feed on corn. They never pair: but in the spring the male gets upon some eminence, crows and claps his wings; on which signal all the females within hearing resort to him. The hen lays seldom above six or seven eggs. When the female is obliged, during the time of incubation, to leave her eggs in quest of food, she covers them up so artfully with moss or dry leaves that it is very difficult to discover them. On this occasion she is extremely tame and tranquil, however wild and timorous at other times. She often keeps to her nest, though strangers attempt to drag her away. As soon as the young ones are hatched, they are seen running with extreme agility after the mother, though sometimes they are not entirely disengaged from the shell. The hen leads them forward for the first time into the woods, to show them ant's eggs and the wild mountain berries, which, while young, are their only food. As they grow older their appetites grow stronger, and they then feed upon the tops of the heather and the cones of the pine tree. In this manner they soon come to perfection. An old black cock is in length twenty-two inches, and weighs nearly four pounds. The bill is dusky; and the plumage of the whole body black, glossed over the neck and rump with a shining blue. The coverts of the wings are of a dusky brown; the inner coverts white; the thighs and legs are covered with dark brown feathers; the toes resemble those of the former species. The tail consists of sixteen black feathers, and is much forked; the exterior feathers bend greatly outwards, and their ends seem as if cut off. The female weighs only two pounds; and its length is one foot six inches. The head and neck are marked with alternate bars of dull red and black; the breast with dusky black and white, but the last predominates. The back, coverts of the wings, and tail, are of the same color as the neck, but the red is deeper. The tail is slightly forked; it consists of eighteen feathers variegated with red and black. The feathers under the tail are white, marked with a few bars of black and orange. This bird hatches its young late in the summer. It lays from six to eight eggs, of a dull yellowish white color, marked with numbers of very small ferruginous specks; and towards the smaller end with some blotches of the same hue.

4. *T. urogallus*, the woodcock, inhabits woody and mountainous countries; in particular, forests of pines, birch trees, and junipers; feeding on the tops of the former and berries of the latter; the first often infects the flesh with such a taste as to render it scarcely eatable. In the spring it calls the females to its haunts with a loud and shrill voice; and is at that time so very inattentive.

tive to its safety as to be very easily shot. It stands perched on a tree, and descends to the females on their first appearance. They lay from eight to sixteen eggs; eight at the first and more as they advance in age. These birds are common in Scandinavia, Germany, France, and several parts of the Alps. They are found in no other part of Great Britain but the Highlands of Scotland, and are very rare even in those parts. They are there called capercalzie, auer-calzie, and in the old law books caperkally; the last signifying the horse of the woods: this species being, in comparison of others of the genus, pre-eminently large. The length of the male is two feet nine inches; its weight sometimes fourteen pounds. The female is much less, the length being only twenty-six inches. The sexes differ also greatly in colors. The bill of the male is of a pale yellow; the head, neck, and back, are elegantly marked with slender lines of gray and black running transversely. The upper part of the breast is of a rich glossy green; the rest of the breast and the belly black, mixed with some white feathers; the sides are marked like the neck; the coverts of the wings crossed with undulated lines of black and reddish brown; the exterior webs of the greater quill-feathers are black: the tail consists of eighteen feathers, the middle of which is the longest; these are black, marked on each side with a few white spots. The legs are very strong, and covered with brown feathers; the edges of the toes are pectinated. Of the female the bill is dusky; the throat red; the head, neck, and back, are marked with transverse bars of red and black; the breast has some white spots on it, and the lower part is of a plain orange color; the belly is barred with pale orange and black; the tips of the feathers are white. The tail is of a deep rust color, barred with black, tipped with white, and consists of sixteen feathers. See SHOOTING.

TETRAPET'ALOUS, *adj.* Gr. τεσσαρες and πεταλον. Such flowers as consist of four leaves round the style.

All the *tetrapetalous* siliquose plants are alkalescent. *Arbutnot.*

TETRAPODOLOGY (τετραπος, and λογος) that branch of zoology which treats of quadrupeds, in the Linnæan system called mammalia.

TETRAPOLIS, an ancient name of Antioch in Syria, because it contained four cities.

TETRARCH, *n. s.* Fr. *tetrarque*; Lat. *tetrarcha*; Gr. τετραρχης. A Roman governor of the fourth part of a province.

All the earth,
Her kings and *tetrarchs*, are their tributaries:
People and nations pay them hourly stipends.

Ben Jonson.

A **TETRARCH** is a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title tetrarch; but it was afterwards applied to any petty king or sovereign; and became synonymous with ethnarch.

TETRASTICK, *n. s.* Gr. τετραστιχος. An epigram or stanza of four verses.

The *tetrastick* obliged Spenser to extend his sense to the length of four lines, which would have been more closely confined in the couplet. *Pope.*

TETRASTYLE, in the ancient architecture, a building, and particularly a temple, with four columns in its front.

TETRICAL, *adj.* } Fr. *tetrique*; Lat. *te-*
TETRICOUS. } *tricus*. Froward; per-
verse; sour.

In this the *tetrical* bassa finding him to excel, gave him as a rare gift to Solymán.

Knolles's History of the Turks.

TETRODON, in ichthyology, a genus of fishes arranged by Linnæus under the class of amphibia, and order of nantes; but placed by Gmelin under the class of pisces, and order of branchiostegi. The jaws are bony, stretched out, and cloven at the point; the aperture of the gills is linear; the body is mucated beneath, and there are no ventral fins. There are thirteen species; of which the most remarkable is *T. lineatus*, called by Mr. Hasselquist *fahaka*, which is the Egyptian and Arabic name. It has of late been found in the Nile about Cairo, but was never known in former times. It is said to grow to a prodigious size. When just caught it pricks the skin if it is taken in the bare hands, and produces small pustules in the same manner as nettles. The flesh is poisonous. Mr. Foster confirms the account of the poisonous nature of a species of tetrodon in his account of New Caledonia.

TETTER, *n. s.* Sax. *τετερη*. A scab; a scurf; a ringworm.

A most instant *tetter* barked about,
Most lazar like, with vile and loathsome crust,
All my smooth body.

Shakspeare. Hamlet.

A scabby *tetter* on their pelts will stick. *Dryden.*

TETUAN, a sea-port of Morocco, in the province of El Garb, on the Mediterranean, within the Straits of Gibraltar. A branch of the Atlas, passing through the province of Tedla, comes within a few miles of the town. The environs are planted with vineyards and gardens, and the oranges are reckoned very superior. Several European consuls and merchants were settled here till 1770, when an Englishman having shot a Moor the emperor banished all Europeans, and would no longer permit any to reside there. A considerable communication, however, is maintained with Gibraltar, whence ships often repair, when the wind is unfavorable for making Tangiers; and our fleets, entering the Mediterranean, often water and victual in the bay. Thirty miles south-east of Tangiers.

TETZEL, or **TESTZEL** (John), a monk of the sixteenth century, whose honest bigotry may be classed among the proximate causes of the Reformation. He was born at Piern upon the Elbe, and, having taken the habit of St. Dominick, received a commission from the archbishop of Mayence, to preach up the indulgences of Leo X. The extravagant power and virtue which he attributed to his commodities, declaring that they were sufficient to procure impunity for a sinner, though he had even violated the mother of God herself! first roused the indignation of Luther, and drew upon him those attacks which were at length transferred from the effect to the cause, and diverted from combating the absurdities themselves to exposing the corruption of the system by which they were sanctioned. The eyes of the

papal government were at length, when too late, opened to the mischief which Tetzal had occasioned, and he received so severe a rebuke from the legate that he is said to have died of a broken heart in 1519.

TEUCER, the son of Scamander by Ida the founder and first king of Phrygia, from whom his subjects were called Teuceri. Dardanus married his daughter Batca, and succeeded him.—Virg. *Æn.* iii. 108.

TECCER, a son of Telamon and brother of Ajax. He built a town in the isle of Cyprus, which he called Salamis from his birth-place.

TEUCRI, a name given the Trojans from Teucer their first king.

TEUCRUM, germander, in botany, a genus of plants belonging to the class of didynamia, and order of gymnospermia; and in the natural system ranging under the forty-second order, verticillatæ. The corolla has no upper lip, is divided into two parts beyond the base, and is divaricated where the stamina issue out. There are thirty species; of which three are natives of Great Britain, viz.

1. *T. chamædrys*, the smaller creeping germander, has fibrous, very creeping, spreading roots; many four cornered, very branched, trailing stalks, nearly a foot long; oval, cuneiform, cut, crenated leaves on short foot-stalks; and reddish flowers, growing almost in a verticillus, on whorls, round the stalk, three on each peduncle; appearing in June and July.

2. *T. scocondonia*, wood sage, or germander, is distinguished by leaves which are heart-shaped, serrated, and petiolated; by racemi, which are lateral and ranged in one row; and by an erect stem. The flowers are straw-colored, and the filaments red. The plant has a bitter taste, and smells like hops with a little mixture of garlic. It is used in brewing in the isle of Jersey instead of hops.

3. *T. scordium*, the common water germander, has creeping perennial roots, sending up many square, procumbent, or trailing stalks, branching diffusely; oblong, indented, serrated, close-sitting, opposite leaves; and small reddish flowers, generally two together, from the sides of the stalks and branches, in July and August. This plant was formerly considered as medicinal, but has now fallen into disuse. It grows naturally in marshy places, in the isle of Ely and other parts of England, and most parts of Europe; and is sometimes admitted into gardens, in moist places, for variety, and as a medicinal plant.

TEURART, an ancient town of Africa, in Fez, seated on a mountain, near the river Za; it was an anciently a very important city.

TEUTHIS, in ichthyology, a genus of fishes belonging to the order of abdominales. The head is somewhat truncated on the fore part; the branchial membrane has five rays; the teeth equal, rigid near each other, forming a regular series. There are two species, viz. 1. *T. hepatus*; and 2. *T. Java*.

TEUTHRAS, king of Mysia. See **TELEPHUS**.

TEUTOBOCHUS, a gigantic king of the Teutones.

TEUTONES, or **TEUTONI**, an ancient people, always by historians joined with the Cimbri;

both seated, according to Mela, beyond the Elbe, on the Sinus Codanus, or Baltic; and there, it is supposed, lay the country of the Teutones, now Ditmarsch; diversity of dialects producing the different terms Teut, Tut, Dit, Tid, and Thod, which in the ancient German language signified people. Of these Teutones Virgil is to be understood in the epithet Teutonicus, an appellation which more lately came to be applied to the Germans in general, and later still the appellation Alemanni.

The **TEUTONIC LANGUAGE** is supposed to have been the language of the ancient Germans, and hence is reckoned amongst the mother tongues. See **PHILOLOGY**.

TEUTONIC ORDER, an order of military knights, established towards the close of the twelfth century, in the Holy Land, where, after the death of Barbarossa, the Germans behaved with so much bravery, that Henry king of Jerusalem, the patriarch, and several other princes, determined to reward their valor by instituting the order. They had at first the title of the knights of St. George, and afterwards were called Equites Mariani, or knights of St. Mary. Among their other obligations it was required that every knight should be of noble parentage; that the order should defend the Christian religion and the Holy Land; that they should exercise hospitality towards the Christians in general, but particularly those of their own country; and that they should with all their power endeavour to propagate and extend the Christian faith and the religion of Jesus. In 1190, having become rich by donations from the superstitious, they elected their first grand master, Henry Walpot, a German, who had distinguished himself by his zeal and valor. In 1191 pope Celestine III. confirmed their privileges already granted, giving them the title of the Teutonic knights of the hospital of St. Mary the Virgin. By the conditions of this bull they owed perpetual continence, obedience, and poverty; obligations which it may well be imagined were not very strictly kept. See **POLAND**, and **PRUSSIA**.

TEWEL, *n.s.* Fr. *tuyau* or *tuyal*. Defined below.

In the back of the forge, against the fire-place, is fixed a thick iron plate, and a taper pipe in it about five inches long, called a *tewel*, or *tewel* iron, which comes through the back of the forge; into this *tewel* is placed the bellows. *Mozon.*

TEWIT, in ornithology. See **TRINGA**.

TEWKESBURY, a market town and borough of England, in the county of Gloucester, situated on the eastern bank of the Avon, near its confluence with the Severn. The access to the town is by several commodious bridges. That over the Avon is a stone structure of considerable length. The town is large, handsome, and populous. It consists mostly of three principal streets, with several lanes and alleys branching off, which are mostly well paved and lighted. The houses in the town are chiefly built of brick, but the old habitations with projecting stones, and pyramidal roofs, have been mostly pulled down. The act for paving and lighting the streets was obtained in 1786; and, from that period, a growing spirit of improvement has diffused itself among the inhabitants. Of the

public buildings the principal is the Abbey church, almost the only remains of the ancient monastery. This structure displays an interesting example of early Norman architecture, combined with specimens of other kinds. It is built in the cathedral form, and consists of a nave, choir, transept, and central tower, with the addition of several chapels. The nave and choir are separated from the aisles by eighteen massive columns sustaining the roof, and four substantial piers which support the tower. The arches above the columns in the nave and over the piers are plain and semicircular, but those of the choir are pointed. Above the crown of the former arches runs a triforium, opening into the nave by a series of double round headed arches, two over each arch. The roof of the nave is ornamented with groins springing from crocket heads over each pillar; and at the intersections are various angels and other figures, playing on different musical instruments. At the west end is a large window, with a pointed arch, which appears to have been introduced within a semicircular arch in 1656. The aisles are lighted with pointed arched windows. These were probably altered to that shape about the beginning of the fourteenth century. In 1796 this was again altered, fitted up with new pews, and otherwise improved, at an expense of £2000. The effect of this portion of the fabric is singularly beautiful. The east end is hexagonal, and is separated from the aisles by six massive short columns, which support pointed arches. Beneath these are some large monuments, and over the arches are windows filled with painted glass. On the south side of the altar are three stone stalls, part of which displays some elegant carving. The ceiling is adorned with a profusion of tracery, and at each intersection is a carved flower or knot of foliage. Branching out from the north and south aisles of the choir are five or six small private chapels or oratorios, containing the tombs or ashes of their respective founders. The Lady chapel is entirely destroyed; but a large arch, through which it was entered from the church, is still seen on the outside. The cloisters were on the south side of the nave, and some fragments of them still remain. The tower is lofty, and, according to the abbey chronicles, was once terminated by a wooden spire, which fell on Easter day 1559: the most remarkable specimens of its architecture are three tiers of arcades; in the upper part the arches of the middlemost tier are intersected. The whole length of the church is 300 feet, of the transept 120. The breadth of the choir and side aisles is seventy feet; of the west front 100. The height from the area to the roof is 120 feet; the height of the tower is 152 feet. The monuments in Tewkesbury church have attracted the attention of various antiquaries. Between two of the pillars on the north side of the choir is an elegant and light chapel of stone, erected by abbot Parker in 1097, over the tomb of Robert Fitz-Hamon, who was slain at Falaise, in Normandy, in 1107, and originally buried in the chapter-house, whence his bones were removed by abbot Robert in 1241. On the north side of the altar is a monument of the most delicate sculpture and

beautiful proportions, in four stages of open arched work, with a tomb beneath, surrounded by an embattled border, and the sides ornamented alternately with single and double arches. This splendid monument appears to have been erected to the memory of Hugh le Despencer, and his wife Elizabeth, daughter of William Montacute earl of Salisbury. Other elegant monuments we have not room to particularise. Tewkesbury abbey was founded in the year 715, by two Saxon brothers, Dodo and Odo, who were then dukes of great opulence and high consideration in the kingdom of Mercia, and the first lords of the manor here. Besides the church, Tewkesbury contains meeting-houses for Independents, Quakers, Baptists, and Methodists. The town-hall is a handsome building. The old town hall, or Tolsey, originally served as a market place; but, after that building was removed, twenty persons entered into an agreement with the corporation to erect the present market-house, in consideration of a grant of the profits of the stalls, &c., for ninety-nine years. The curious old structure which had for centuries been used as the borough jail was originally the companie or bell tower annexed to the abbey: this was pulled down in 1817, and a most substantial and elegant school, for the education of children on the national or Bell's system, erected in its place. The new jail is a neat and suitable building, situate at the top of the High-street. The house of industry is singularly spacious and commodious, and situate on Holme hill, near the entrance of the town from Gloucester. The charitable institutions in the town are a free grammar school, endowed charity school, schools on the national and Lancasterian plans, a great number of alms-houses, a dispensary, a lying-in charity, and numerous other benevolent associations. Tewkesbury had once a considerable share in the clothing business, but this trade has long since declined. It was likewise noted for its mustard. At present the chief manufacture carried on in the town is that of stocking framework knitting, particularly in cotton. A considerable trade is also carried on in malting, and the making of nails. Tewkesbury was incorporated by a charter granted by queen Elizabeth, and confirmed by James I.; but, in the reign of James II., the corporate officers surrendered their seal to that monarch, who in his second year re-incorporated them by the names of the mayor, alderman, and common council. The revolution which immediately followed prevented the charter from being carried into effect, and the town remained in a state of uncertainty as to its government till the thirteenth of William III., when it was settled in the present form. By this, the government of the town is vested in two bailiffs and four justices, annually chosen, and a recorder. The corporate body consists of twenty-four principal burgesses, and the same number of assistants; but, as each principal burgess holds also the office of assistant, the members of the corporation are now uniformly confined to twenty-four persons, instead of forty-eight as formerly. The town sends two members to parliament, the privilege of which was obtained from James I. in 1609. The right of election

is possessed by the freemen and freeholders. It was at Tewkesbury that the last battle was fought between the adherents of the houses of York and Lancaster, which it is well known proved fatal to the latter. The field on which it was fought is still called the bloody meadow, and is situated about half a mile from the town. In the civil wars, in the reign of Charles I., Tewkesbury was the scene of many severe contests. Markets on Wednesday and Saturday, and various annual fairs. Ten miles north of Gloucester, and 102 W. N. W. of London.

TEW'TAW, *v. a.* Formed from *tew* by reduplication. To beat; to break.

The method and way of watering, pilling, breaking, and *tewtawing* of hemp and flax, is a particular business. *Mortimer.*

TEXAS, a tract of country in North America, claimed by the United States as a part of Louisiana, and by Spain as a part of the Internal provinces, included in the intendency of San Luis Potosi. It is bounded north by Red River, east by the state of Louisiana, south by the gulf of Mexico, and west by the del Norte; containing upwards of 100,000 square miles. There are some scattering Spanish presidios in this country, yet it is for the most part a wilderness. The population was estimated in 1807 at 7000. The interior towards Red River is barren, but the part towards the gulf of Mexico resembles the southern part of Louisiana.

TEXEL, an island of the Netherlands, at the entrance of the Zuyder Zee, separated from North Holland by the narrow channel called the Mars-diep. Its form is oblong, twelve miles in length, and about six in breadth, and it is secured from the sea by strong dikes. The soil is well fitted for sheep pasture, and it has long been noted for its cheese. Besides the town of Texel, it contains six villages, and has in all about 5000 inhabitants. It has a large and secure harbour, with a fort which commands the entrance; it has likewise a commodious roadstead on the east. It was in the neighbourhood of the Texel that admiral Blake defeated the Dutch under Van Tromp, in 1653: in 1673 another battle was fought near this, between the Dutch and the combined fleets of England and France, with doubtful success; a result far different from that of an encounter near the Texel in the end of August 1799, between the British and Dutch fleets, when the latter, disaffected to the republican government, surrendered after a slight resistance.

TEXT, *n. s.* } Fr. *texte*; Latin
 TEXTMAN, *n. s.* } *textus*. That on
 TEXTUARY, *adj.* & *n. s.* } which a comment is written; a sentence of scripture: textman and textuary mean one versed in texts: textury also means contained in the text; or serving as a text.

In religion

What error, but some sober brow
 Will bless it, and approve it with a *text*?

Shakspeare.

Some prime articles of faith are not delivered in a literal or catechistical form of speech, but are collected and concluded by argumentation out of sentences of scripture, and by comparing of sundry texts with one another, *White.*

Men's daily occasions require the doing of a thousand things, which it would puzzle the best *textman* readily to bethink himself of a sentence in the Bible, clear enough to satisfy a scrupulous conscience of the lawfulness of. *Sanderson.*

He extends the exclusion unto twenty days, which in the *textuary* sense is fully accomplished in one. *Browne.*

I see no ground why this reason should be *textuary* to ours, or that God intended him an universal headship. *Glanville.*

We expect your next

Should be no comment, but a *text*,
 To tell how modern beasts are *text*. *Waller.*

His mind he should fortify with some few *texts*, which are home and apposite to his case. *South.*

TEXTURE, *n. s.* } Lat. *textus*. The act or
 TEXTILE, *adj.* } manner of weaving; a
 TEXTURINE. } web or thing woven; particular combination of parts: the adjective corresponding.

The placing of the tangible parts in length or transverse, as in the warp and woof of *textiles*. *Bacon's Natural History.*

The materials of them were not from any herb, as other *textiles*, but from a stone called *amiantus*. *Wilkins.*

Spirits—

Nor in their liquid *texture* mortal wound
 Receive, no more than can the fluid air. *Milton.*

Under state of richest *texture* spread. *Id.*
 Skins, although a natural habit unto all before the invention of *texture*, were something more unto Adam. *Browne.*

It is a wonderful artifice, how newly hatched maggots, not the parent animal, because she emits no web, nor hath any *texturine* art, can convolve the stubborn leaf, and bind it with the thread it weaves from its body. *Derham.*

A veil of richest *texture* wrought she wears. *Pope.*

Others, far in the grassy dale,
 Their humble *texture* weave. *Thomson's Spring.*

TEXTURE properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other, as in the webs of spiders, or in the cloths, stuffs, &c. Texture is also used in speaking of any union or constituent particles of a concrete body, whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, compressing, attracting, or any other way. In which sense we say, a close compact texture, a lax porous texture, a regular or irregular texture, &c
